where $p=i$ ---- if $m=1$ and $p=-i$ ---- if $m=2$, and the Bessel function $K^{(2)}(z)$ is computed in the right half-plane only. Continuation of $K^{(2)}(z)$ to the left half-plane is computed in terms of the Bessel function $I^{(2)}(z)$. These functions are evaluated using a variety of different techniques, depending on the region under consideration.

When $N$ is greater than 1, extra values of $H^{(m)}(z)$ are computed using recurrence relations.
For very large \(|z|\) or \(((\nu)+N-1)\), argument reduction will cause total loss of accuracy, and so no computation is performed. For slightly smaller \(|z|\) or \(((\nu)+N-1)\), the computation is performed but results are accurate to less than half of machine precision. If \(|z|\) is very small, near the machine underflow threshold, or \(((\nu)+N-1)\) is too large, there is a risk of overflow and so no computation is performed. In all the above cases, a warning is given by the routine.

4. References

5. Parameters

1: \(M\) -- INTEGER Input
   On entry: the kind of functions required.
   \((1)\)
   If \(M = 1\), the functions are \(H_{\nu}(z)\).
   \((2)\)
   If \(M = 2\), the functions are \(H_{\nu}(z)\).
   Constraint: \(M = 1\) or 2.

2: \(FNU\) -- DOUBLE PRECISION Input
   On entry: the order, \((\nu)\), of the first member of the sequence of functions. Constraint: \(FNU \geq 0.0\).

3: \(Z\) -- COMPLEX(KIND(1.0D0)) Input
   On entry: the argument \(z\) of the functions. Constraint: \(Z \neq (0.0, 0.0)\).

4: \(N\) -- INTEGER Input
   On entry: the number, \(N\), of members required in the sequence \(H_{\nu}, H_{\nu+1}, \ldots, H_{\nu+N-1}\). Constraint: \(N \geq 1\).

5: \(SCALE\) -- CHARACTER*1 Input
   On entry: the scaling option.
   If \(SCALE = 'U'\), the results are returned unscaled.
   If \(SCALE = 'S'\), the results are returned scaled by the
-iz
factor e when M = 1, or by the factor e when M = 2.
Constraint: SCALE = 'U' or 'S'.

6: CY(N) -- COMPLEX(KIND(1.0D)) array Output
On exit: the N required function values: CY(i) contains (M)
H
, for i=1,2,...,N.
(nu)+i-1

7: NZ -- INTEGER Output
On exit: the number of components of CY that are set to zero
due to underflow. If NZ > 0, then if Imz>0.0 and M = 1, or
Imz<0.0 and M = 2, elements CY(1), CY(2),...,CY(NZ) are set
to zero. In the complementary half-planes, NZ simply states
the number of underflows, and not which elements they are.

8: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not
familiar with this parameter (described in the Essential
Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see
Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
On entry M /= 1 and M /= 2,
or FNU < 0.0,
or Z = (0.0, 0.0),
or N < 1,
or SCALE /= 'U' or 'S'.

IFAIL= 2
No computation has been performed due to the likelihood of
overflow, because ABS(Z) is less than a machine-dependent
threshold value (given in the Users’ Note for your
implementation).
IFAIL= 3
No computation has been performed due to the likelihood of
overflow, because FNU + N - 1 is too large — how large
depends on Z and the overflow threshold of the machine.

IFAIL= 4
The computation has been performed, but the errors due to
argument reduction in elementary functions make it likely
that the results returned by S17DLF are accurate to less
than half of machine precision. This error exit may occur if
either ABS(Z) or FNU + N - 1 is greater than a machine-
dependent threshold value (given in the Users’ Note for
your implementation).

IFAIL= 5
No computation has been performed because the errors due to
argument reduction in elementary functions mean that all
precision in results returned by S17DLF would be lost. This
error exit may occur when either of ABS(Z) or FNU + N - 1 is
greater than a machine-dependent threshold value (given in
the Users’ Note for your implementation).

IFAIL= 6
No results are returned because the algorithm termination
condition has not been met. This may occur because the
parameters supplied to S17DLF would have caused overflow or
underflow.

7. Accuracy

All constants in subroutine S17DLF are given to approximately 18
digits of precision. Calling the number of digits of precision in
the floating-point arithmetic being used t, then clearly the
maximum number of correct digits in the results obtained is
limited by p=min(t,18). Because of errors in argument reduction
when computing elementary functions inside S17DLF, the actual
number of correct digits is limited, in general, by p-s, where
s=\max(1,\log |z|,|\log (nu)|) represents the number of digits
lost due to the argument reduction. Thus the larger the values of
|z| and (nu), the less the precision in the result. If S17DLF is
called with N>1, then computation of function values via
recurrence may lead to some further small loss of accuracy.

If function values which should nominally be identical are
computed by calls to S17DLF with different base values of (nu)
and different N, the computed values may not agree exactly.
Empirical tests with modest values of (nu) and z have shown that
the discrepancy is limited to the least significant 3-4 digits of
precision.
8. Further Comments

The time taken by the routine for a call of S17DLF is approximately proportional to the value of \( N \), plus a constant. In general it is much cheaper to call S17DLF with \( N \) greater than 1, rather than to make \( N \) separate calls to S17DLF.

Paradoxically, for some values of \( z \) and \( (\nu) \), it is cheaper to call S17DLF with a larger value of \( N \) than is required, and then discard the extra function values returned. However, it is not possible to state the precise circumstances in which this is likely to occur. It is due to the fact that the base value used to start recurrence may be calculated in different regions for different \( N \), and the costs in each region may differ greatly.

9. Example

The example program prints a caption and then proceeds to read sets of data from the input data stream. The first datum is a value for the kind of function, \( M \), the second is a value for the order \( FNU \), the third is a complex value for the argument, \( Z \), and the fourth is a value for the parameter \( SCALE \). The program calls the routine with \( N = 2 \) to evaluate the function for orders \( FNU \) and \( FNU + 1 \), and it prints the results. The process is repeated until the end of the input data stream is encountered.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
3. Description

This routine evaluates an approximation to the modified Bessel Function of the second kind $K(x)$.

Note: $K(x)$ is undefined for $x \leq 0$ and the routine will fail for such arguments.

The routine is based on five Chebyshev expansions:

For $0 < x \leq 1$,

$K(x) = -\ln x \cdot a\sum r=0^{2} T_r(t) + b\sum r=0 T_r(t)$, where $t = 2x - 1$;

For $1 < x \leq 2$,

$K(x) = e^{-x} \cdot c\sum r=0 T_r(t)$, where $t = 2x - 3$;

For $2 < x \leq 4$,

$K(x) = e^{-x} \cdot d\sum r=0 T_r(t)$, where $t = x - 3$;

For $x > 4$,

$K(x) = e^{-x} \cdot e_{9-x}\sum r=0 T_r(t)$, where $t = \frac{9-x}{1+x}$

For $x$ near zero, $K(x) \approx -(\gamma) - \ln x$, where $(\gamma)$ denotes Euler's constant. This approximation is used when $x$ is sufficiently small for the result to be correct to machine precision.
For large $x$, where there is a danger of underflow due to the smallness of $K$, the result is set exactly to zero.

4. References

5. Parameters

1: $X$ -- DOUBLE PRECISION
   Input
   On entry: the argument $x$ of the function. Constraint: $X > 0$.

2: IFAIL -- INTEGER
   Input/Output
   On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
   On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
   $X \leq 0.0$, $K$ is undefined. On soft failure the routine returns zero.

7. Accuracy

Let $(\delta)$ and $(\epsilon)$ be the relative errors in the argument and result respectively.

If $(\delta)$ is somewhat larger than the machine precision (i.e., if $(\delta)$ is due to data errors etc), then $(\epsilon)$ and $(\delta)$ are approximately related by:

$$| \frac{xK(x)}{K(x)} | \approx \frac{1}{| \delta |}.$$ 

Figure 1 shows the behaviour of the error amplification factor $| xK(x) |$. 
Figure 1
Please see figure in printed Reference Manual

However, if (delta) is of the same order as machine precision, then rounding errors could make (epsilon) slightly larger than the above relation predicts.

For small x, the amplification factor is approximately | --- |, which implies strong attenuation of the error, but in general (epsilon) can never be less than the machine precision.

For large x, (epsilon)^x = x(delta) and we have strong amplification of the relative error. Eventually K, which is asymptotically 0

-e
\sqrt{x}

given by ---, becomes so small that it cannot be calculated without underflow and hence the routine will return zero. Note that for large x the errors will be dominated by those of the Fortran intrinsic function EXP.

8. Further Comments

For details of the time taken by the routine see the appropriate the Users’ Note for your implementation.

9. Example

The example program reads values of the argument x from a file, evaluates the function at each value of x and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S18ADF returns the value of the modified Bessel Function $K_1(x)$ via the routine name.

2. Specification

```plaintext
DOUBLE PRECISION FUNCTION S18ADF (X, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X
```

3. Description

This routine evaluates an approximation to the modified Bessel Function of the second kind $K_1(x)$.

Note: $K_1(x)$ is undefined for $x \leq 0$ and the routine will fail for such arguments.

The routine is based on five Chebyshev expansions:

For $0 < x \leq 1$,

$$
K_1(x) = -\frac{\ln x}{x} + \sum_{r=0}^{1} a_r T_r(t),
$$

where $t = 2x - 1$.

For $1 < x \leq 2$,

$$
K_1(x) = e^{-x} \sum_{r=0}^{1} c_r T_r(t),
$$

where $t = 2x - 3$.

For $2 < x \leq 4$,

$$
K_1(x) = e^{-x} \sum_{r=0}^{1} d_r T_r(t),
$$

where $t = x - 3$. 

Where $T_r(t)$ are Chebyshev polynomials of the first kind.
For $x > 4$,
\[
K(x) = \frac{-x}{e^{9-x}} > \frac{e^{-t}}{1 + x}, \quad \text{where } t = \frac{r}{1 + x}, \quad \sqrt{x} r = 0
\]

For $x$ near zero, $K(x) \approx -\frac{1}{x}$. This approximation is used when $x$ is sufficiently small for the result to be correct to machine precision. For very small $x$ on some machines, it is impossible to calculate $-\frac{1}{x}$ without overflow and the routine must fail.

For large $x$, where there is a danger of underflow due to the smallness of $K$, the result is set exactly to zero.

4. References

5. Parameters

1: X -- DOUBLE PRECISION
   Input
   On entry: the argument $x$ of the function. Constraint: $X > 0$.

2: IFAIL -- INTEGER
   Input/Output
   On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
   On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
   $X \leq 0.0$, $K$ is undefined. On soft failure the routine returns zero.

IFAIL= 2
CHAPTER 15. CHAPTER N

X is too small, there is a danger of overflow. On soft failure the routine returns approximately the largest representable value.

7. Accuracy

Let \( (\Delta) \) and \( (\varepsilon) \) be the relative errors in the argument and result respectively.

If \( (\Delta) \) is somewhat larger than the machine precision (i.e., if \( (\Delta) \) is due to data errors etc), then \( (\varepsilon) \) and \( (\Delta) \) are approximately related by:

\[
\begin{vmatrix}
\frac{|xK(x) - K(x)|}{0 1} \\
|K(x)|
\end{vmatrix}
\approx \frac{|\Delta|}{K(x)}.
\]

Figure 1 shows the behaviour of the error amplification factor

\[
\begin{vmatrix}
\frac{|xK(x) - K(x)|}{0 1} \\
|K(x)|
\end{vmatrix}
\]

However if \( (\Delta) \) is of the same order as the machine precision, then rounding errors could make \( (\varepsilon) \) slightly larger than the above relation predicts.

For small \( x \), \( (\varepsilon) \approx (\Delta) \) and there is no amplification of errors.

For large \( x \), \( (\varepsilon) \approx x(\Delta) \) and we have strong amplification of the relative error. Eventually \( K \), which is asymptotically given by \( \frac{1}{e^{\frac{-x}{x}}} \), becomes so small that it cannot be calculated without underflow and hence the routine will return zero. Note that for large \( x \) the errors will be dominated by those of the Fortran intrinsic function EXP.
8. Further Comments

For details of the time taken by the routine see the Users' Note for your implementation.

9. Example

The example program reads values of the argument $x$ from a file, evaluates the function at each value of $x$ and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
\[ I(x) = e^{a \sum_{r=0}^{\infty} \frac{t(t)}{r!}} \quad (4) \]

For \(4 < x \leq 12\),
\[ I(x) = e^{b \sum_{r=0}^{\infty} \frac{t}{r!}} \quad (4) \]

For \(x > 12\),
\[ I(x) = e^{c \sum_{r=0}^{\infty} \frac{t}{r!}} \quad (12) \]

For small \(x\), \(I(x) \approx 1\). This approximation is used when \(x\) is sufficiently small for the result to be correct to machine precision.

For large \(x\), the routine must fail because of the danger of overflow in calculating \(e^x\).

4. References

5. Parameters

1: X -- DOUBLE PRECISION Input
   On entry: the argument \(x\) of the function.

2: IFAIL -- INTEGER Input/Output
   On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
   On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:
IFAIL = 1

X is too large. On soft failure the routine returns the approximate value of I (x) at the nearest valid argument.

7. Accuracy

Let (delta) and (epsilon) be the relative errors in the argument and result respectively.

If (delta) is somewhat larger than the machine precision (i.e., if (delta) is due to data errors etc), then (epsilon) and (delta) are approximately related by:

\[
\frac{|xI(x)|}{|I(x)|} \approx \frac{1}{\epsilon_0} (\delta).
\]

Figure 1 shows the behaviour of the error amplification factor

\[
\frac{|xI(x)|}{|I(x)|} \approx \frac{1}{\epsilon_0}.
\]

However if (delta) is of the same order as machine precision, then rounding errors could make (epsilon) slightly larger than the above relation predicts.

For small \( x \) the amplification factor is approximately \( \frac{1}{\epsilon_0} \), which implies strong attenuation of the error, but in general (epsilon) can never be less than the machine precision.

For large \( x \), \( \epsilon_0 \approx x (\delta) \) and we have strong amplification of errors. However the routine must fail for quite moderate values of \( x \), because \( I(x) \) would overflow; hence in practice the loss of accuracy for large \( x \) is not excessive. Note that for large \( x \) the errors will be dominated by those of the Fortran intrinsic function EXP.
8. Further Comments

For details of the time taken by the routine see the Users' Note for your implementation.

9. Example

The example program reads values of the argument x from a file, evaluates the function at each value of x and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

S18 -- Approximations of Special Functions
S18AFF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S18AFF returns a value for the modified Bessel Function $I_1(x)$, via the routine name.

2. Specification

    DOUBLE PRECISION FUNCTION S18AFF (X, IFAIL)
    INTEGER IFAIL
    DOUBLE PRECISION X

3. Description

This routine evaluates an approximation to the modified Bessel Function of the first kind $I_1(x)$.

Note: $I_{-x} = -I_1(x)$, so the approximation need only consider $x >= 0$.

The routine is based on three Chebyshev expansions:

For $0 < x <= 4$, 

    --', (x)^2
\[ I(x) = x^{\frac{a}{t}} \text{ for } 4 < x \leq 12, \]
\[ I(x) = e^{\frac{x-8}{t}} \text{ for } x > 12, \]
\[ I(x) \approx x \text{ for small } x, \]
\[ I(x) = 2(\frac{-1}{x}) \text{ for large } x. \]

For small \( x \), \( I(x) \approx x \). This approximation is used when \( x \) is sufficiently small for the result to be correct to machine precision.

For large \( x \), the routine must fail because \( I(x) \) cannot be represented without overflow.

4. References

5. Parameters

1: \( X \) -- DOUBLE PRECISION
   \text{ Input}
   \text{ On entry: the argument } x \text{ of the function.}

2: \( IFAIL \) -- INTEGER
   \text{ Input/Output}
   \text{ On entry: } IFAIL \text{ must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.}
   \text{ On exit: } IFAIL = 0 \text{ unless the routine detects an error (see Section 6).}

6. Error Indicators and Warnings

Errors detected by the routine:
IFAIL= 1

X is too large. On soft failure the routine returns the
approximate value of I (x) at the nearest valid argument.

7. Accuracy

Let (delta) and (epsilon) be the relative errors in the argument
and result respectively.

If (delta) is somewhat larger than the machine precision (i.e.,
if (delta) is due to data errors etc), then (epsilon) and (delta)
are approximately related by:

\[
\frac{|xI(x) - I(x)|}{|I(x)|} \approx \frac{(\epsilon)}{(\delta)}
\]

Figure 1 shows the behaviour of the error amplification factor

However if (delta) is of the same order as machine precision,
then rounding errors could make (epsilon) slightly larger than
the above relation predicts.

For small x, (epsilon) ~ (delta) and there is no amplification of
errors.

For large x, (epsilon) ~ x(epsilon) and we have strong amplification
of errors. However the routine must fail for quite moderate
values of x because I (x) would overflow; hence in practice the

loss of accuracy for large x is not excessive. Note that for
large x, the errors will be dominated by those of the Fortran
intrinsic function EXP.

---

S18 -- Approximations of Special Functions
S18DCF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S18DCF returns a sequence of values for the modified Bessel functions $K_n(z)$ for complex $z$, non-negative $(\nu)$ and $(\nu)+n, n=0,1,...,N-1,$ with an option for exponential scaling.

2. Specification

```fortran
SUBROUTINE S18DCF (FNU, Z, N, SCALE, CY, NZ, IFAIL)
INTEGER N, NZ, IFAIL
DOUBLE PRECISION FNU
COMPLEX(KIND(1.0D0)) Z, CY(N)
CHARACTER*1 SCALE
```

3. Description

This subroutine evaluates a sequence of values for the modified Bessel function $K_n(z)$, where $z$ is complex, $-(\pi) < \arg z \leq (\nu)$, $(\nu)$ is the real, non-negative order. The $N$-member sequence is generated for orders $(\nu), (\nu)+1,...,(\nu)+N-1$. Optionally, the sequence is scaled by the factor $e^{i\pi\nu}$.

The routine is derived from the routine CBESK in Amos [2].

Note: although the routine may not be called with $(\nu)$ less than zero, for negative orders the formula $K_{-(\nu)}(z)=K_{(\nu)}(z)$ may be used.
When \( N \) is greater than 1, extra values of \( K(z) \) are computed using recurrence relations.

For very large \(|z|\) or \(((\nu)+N-1)\), argument reduction will cause total loss of accuracy, and so no computation is performed. For slightly smaller \(|z|\) or \(((\nu)+N-1)\), the computation is performed but results are accurate to less than half of machine precision. If \(|z|\) is very small, near the machine underflow threshold, or \(((\nu)+N-1)\) is too large, there is a risk of overflow and so no computation is performed. In all the above cases, a warning is given by the routine.

4. References

5. Parameters

1: \( \text{FNU -- DOUBLE PRECISION Input} \)  
   On entry: the order, \((\nu)\), of the first member of the sequence of functions. Constraint: \( \text{FNU} \geq 0.0 \).

2: \( Z -- \text{COMPLEX(KIND(1.0D0)) Input} \)  
   On entry: the argument \( z \) of the functions. Constraint: \( Z \neq (0.0, 0.0) \).

3: \( N -- \text{INTEGER Input} \)  
   On entry: the number, \( N \), of members required in the sequence \( K(\nu)(z) \), \( K((\nu)+1)(z) \), ..., \( K((\nu)+N-1)(z) \). Constraint: \( N \geq 1 \).

4: \( \text{SCALE -- CHARACTER*1 Input} \)  
   On entry: the scaling option. 
   If \( \text{SCALE} = 'U' \), the results are returned unscaled. 
   If \( \text{SCALE} = 'S' \), the results are returned scaled by the \( z \) factor \( e^{z} \). Constraint: \( \text{SCALE} = 'U' \) or \( 'S' \).

5: \( \text{CY(N) -- COMPLEX(KIND(1.0D)) array Output} \) On exit: the \( N \) required function values: \( \text{CY}(i) \) contains
K (z), for i=1,2,...,N.
(nu)+i-1

6: NZ -- INTEGER Output
On exit: the number of components of CY that are set to zero
due to underflow. If NZ > 0 and Rez>=0.0, elements CY(1),CY
(2),...,CY(NZ) are set to zero. If Rez<0.0, NZ simply states
the number of underflows, and not which elements they are.

7: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not
familiar with this parameter (described in the Essential
Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see
Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
On entry FNU < 0.0,
or Z = (0.0, 0.0),
or N < 1,
or SCALE /= 'U' or 'S'.

IFAIL= 2
No computation has been performed due to the likelihood of
overflow, because ABS(Z) is less than a machine-dependent
threshold value (given in the Users’ Note for your
implementation).

IFAIL= 3
No computation has been performed due to the likelihood of
overflow, because FNU + N - 1 is too large - how large
depends on Z and the overflow threshold of the machine.

IFAIL= 4
The computation has been performed, but the errors due to
argument reduction in elementary functions make it likely
that the results returned by S18DCF are accurate to less
than half of machine precision. This error exit may occur if
either $\text{ABS}(z)$ or $\text{FNU} + N - 1$ is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

IFAIL= 5
No computation has been performed because the errors due to argument reduction in elementary functions mean that all precision in results returned by S18DCF would be lost. This error exit may occur when either $\text{ABS}(z)$ or $\text{FNU} + N - 1$ is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

IFAIL= 6
No results are returned because the algorithm termination condition has not been met. This may occur because the parameters supplied to S18DCF would have caused overflow or underflow.

7. Accuracy

All constants in subroutine S18DCF are given to approximately 18 digits of precision. Calling the number of digits of precision in the floating-point arithmetic being used $t$, then clearly the maximum number of correct digits in the results obtained is limited by $p=\min(t,18)$. Because of errors in argument reduction when computing elementary functions inside S18DCF, the actual number of correct digits is limited, in general, by $p-s$, where $s=\max(1,\log_{10}|z|,\log_{10} (\text{nu}))$ represents the number of digits lost due to the argument reduction. Thus the larger the values of $|z|$ and $(\text{nu})$, the less the precision in the result. If S18DCF is called with $N>1$, then computation of function values via recurrence may lead to some further small loss of accuracy.

If function values which should nominally be identical are computed by calls to S18DCF with different base values of $(\text{nu})$ and different $N$, the computed values may not agree exactly. Empirical tests with modest values of $(\text{nu})$ and $z$ have shown that the discrepancy is limited to the least significant 3-4 digits of precision.

8. Further Comments

The time taken by the routine for a call of S18DCF is approximately proportional to the value of $N$, plus a constant. In general it is much cheaper to call S18DCF with $N$ greater than 1, rather than to make $N$ separate calls to S18DCF.

Paradoxically, for some values of $z$ and $(\text{nu})$, it is cheaper to
call S18DCF with a larger value of N than is required, and then discard the extra function values returned. However, it is not possible to state the precise circumstances in which this is likely to occur. It is due to the fact that the base value used to start recurrence may be calculated in different regions for different N, and the costs in each region may differ greatly.

Note that if the function required is \( K_0(x) \) or \( K_1(x) \), i.e.,
\[
\begin{align*}
(nu) &= 0.0 \text{ or } 1.0, \\
\end{align*}
\]
where \( x \) is real and positive, and only a single function value is required, then it may be much cheaper to call S18ACF, S18ADF, S18CCF(*) or S18CDF(*), depending on whether a scaled result is required or not.

9. Example

The example program prints a caption and then proceeds to read sets of data from the input data stream. The first datum is a value for the order FNU, the second is a complex value for the argument, Z, and the third is a value for the parameter SCALE. The program calls the routine with \( N = 2 \) to evaluate the function for orders FNU and FNU + 1, and it prints the results. The process is repeated until the end of the input data stream is encountered.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
3. Description

This subroutine evaluates a sequence of values for the modified Bessel function $I_{\nu}(z)$, where $z$ is complex, $-(\pi) < \text{arg} z \leq \nu$ ($\pi$), and $\nu$ is the real, non-negative order. The $N$-member sequence is generated for orders $\nu$, $\nu+1$, ..., $\nu+N-1$.

Optionally, the sequence is scaled by the factor $e^{-|\text{Re}z|}$.

The routine is derived from the routine CBESI in Amos [2].

Note: although the routine may not be called with $\nu$ less than zero, for negative orders the formula

$$I_{\nu}(z) = I_{-\nu}(z) + \frac{\sin(\pi \nu)}{(\pi \nu)} K_{\nu}(z)$$

may be used (for $-(\nu)$, $\nu$, $\pi$, $\nu$, $\pi$, $\nu$, see S18DCF).

When $N$ is greater than 1, extra values of $I_{\nu}(z)$ are computed using recurrence relations.

For very large $|z|$ or $(\nu+N-1)$, argument reduction will cause total loss of accuracy, and so no computation is performed. For slightly smaller $|z|$ or $(\nu+N-1)$, the computation is performed but results are accurate to less than half of machine precision. If $\text{Re}(z)$ is too large and the unscaled function is required, there is a risk of overflow and so no computation is performed. In all the above cases, a warning is given by the routine.

4. References

5. Parameters

1: FNU -- DOUBLE PRECISION Input
   On entry: the order, $\nu$, of the first member of the sequence of functions. Constraint: FNU $\geq 0.0$. 

```fortran
DOUBLE PRECISION FNU
COMPLEX(KIND(1.0D0)) Z, CY(N)
CHARACTER*1 SCALE
```
2: Z -- COMPLEX(KIND(1.0DO))  
   On entry: the argument z of the functions.

3: N -- INTEGER  
   On entry: the number, N, of members required in the sequence
   \( I(z), I(z+1), \ldots, I(z+N-1) \) of the functions. Constraint: \( N \geq 1 \).

4: SCALE -- CHARACTER*1  
   On entry: the scaling option.
   If SCALE = 'U', the results are returned unscaled.
   If SCALE = 'S', the results are returned scaled by the factor \( e^{-|Re(z)|} \).
   Constraint: SCALE = 'U' or 'S'.

5: CY(N) -- COMPLEX(KIND(1.0D)) array  
   On exit: the N required function values: CY(i) contains
   \( I(z+i-1) \) for \( i=1,2,\ldots,N \).

6: NZ -- INTEGER  
   On exit: the number of components of CY that are set to zero due to underflow.
   If NZ > 0, then elements CY(N-NZ+1),CY(N-NZ+2),...,CY(N) are set to zero.

7: IFAIL -- INTEGER  
   On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
   On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1  
On entry FNU < 0.0,

or N < 1,
or SCALE /= 'U' or 'S'.

IFAIL= 2
No computation has been performed due to the likelihood of overflow, because real(Z) is greater than a machine-dependent threshold value (given in the Users' Note for your implementation). This error exit can only occur when SCALE = 'U'.

IFAIL= 3
The computation has been performed, but the errors due to argument reduction in elementary functions make it likely that the results returned by S18DEF are accurate to less than half of machine precision. This error exit may occur when either ABS(Z) or FNU + N - 1 is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

IFAIL= 4
No computation has been performed because the errors due to argument reduction in elementary functions mean that all precision in results returned by S18DEF would be lost. This error exit may occur when either ABS(Z) or FNU + N - 1 is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

IFAIL= 5
No results are returned because the algorithm termination condition has not been met. This may occur because the parameters supplied to S18DEF would have caused overflow or underflow.

7. Accuracy

All constants in subroutine S18DEF are given to approximately 18 digits of precision. Calling the number of digits of precision in the floating-point arithmetic being used t, then clearly the maximum number of correct digits in the results obtained is limited by p=min(t,18). Because of errors in argument reduction when computing elementary functions inside S18DEF, the actual number of correct digits is limited, in general, by p-s, where s=max(1,|log |z||,|log (nu)|) represents the number of digits lost due to the argument reduction. Thus the larger the values of |z| and (nu), the less the precision in the result. If S18DEF is called with N>1, then computation of function values via recurrence may lead to some further small loss of accuracy.

If function values which should nominally be identical are computed by calls to S18DEF with different base values of (nu)
and different $N$, the computed values may not agree exactly. Empirical tests with modest values of $(\nu)$ and $z$ have shown that the discrepancy is limited to the least significant 3-4 digits of precision.

8. Further Comments

The time taken by the routine for a call of S18DEF is approximately proportional to the value of $N$, plus a constant. In general it is much cheaper to call S18DEF with $N$ greater than 1, rather than to make $N$ separate calls to S18DEF.

Paradoxically, for some values of $z$ and $(\nu)$, it is cheaper to call S18DEF with a larger value of $N$ than is required, and then discard the extra function values returned. However, it is not possible to state the precise circumstances in which this is likely to occur. It is due to the fact that the base value used to start recurrence may be calculated in different regions for different $N$, and the costs in each region may differ greatly.

Note that if the function required is $I_0(x)$ or $I_1(x)$, i.e.,

$$(\nu)=0.0 \text{ or } 1.0, \text{ where } x \text{ is real and positive, and only a single function value is required, then it may be much cheaper to call S18AEF, S18AFF, S18CEF(*) or S18CFF(*), depending on whether a scaled result is required or not.}$$

9. Example

The example program prints a caption and then proceeds to read sets of data from the input data stream. The first datum is a value for the order $FNU$, the second is a complex value for the argument, $Z$, and the third is a value for the parameter $SCALE$. The program calls the routine with $N = 2$ to evaluate the function for orders $FNU$ and $FNU + 1$, and it prints the results. The process is repeated until the end of the input data stream is encountered.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
CHAPTER 15. CHAPTER N

not included in the Foundation Library.

1. Purpose

S19AAF returns a value for the Kelvin function \( \text{ber} \ x \) via the
routine name.

2. Specification

```plaintext
DOUBLE PRECISION FUNCTION S19AAF (X, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X
```

3. Description

This routine evaluates an approximation to the Kelvin function
\( \text{ber} x \).

Note: \( \text{ber} (-x) = \text{ber} x \), so the approximation need only consider
\( x > 0.0 \).

The routine is based on several Chebyshev expansions:

For \( 0 \leq x \leq 5 \),

\[
\begin{align*}
\text{ber} x &= \sum_{r=0}^{(5)} \left( \frac{x}{r} \right)^{4r} T_r(t) \\
&= \sum_{r=0}^{(5)} \left( \frac{x}{r} \right)^{4r} T_r \left( 2 \left( \frac{x}{r} \right) - 1 \right)
\end{align*}
\]

For \( x > 5 \),

\[
\begin{align*}
\text{ber} x &= \frac{x^{\sqrt{2}}}{\sqrt{\pi} x^{\frac{1}{2}}} \left[ (1 + a(t)) \cos(\alpha) + b(t) \sin(\alpha) \right] \\
&\quad - \frac{x^{-\sqrt{2}}}{\sqrt{\pi} x^{\frac{1}{2}}} \left[ (1 + c(t)) \sin(\beta) + d(t) \cos(\beta) \right]
\end{align*}
\]

where \( (\alpha) = \frac{\pi}{2} \) and \( (\beta) = \frac{\pi}{2} + \frac{\pi}{2} \).
and a(t), b(t), c(t), and d(t) are expansions in the variable 

\[
t = \frac{1}{x}.
\]

When \( x \) is sufficiently close to zero, the result is set directly to \( \text{ber} = 0 = 1.0 \).

For large \( x \), there is a danger of the result being totally inaccurate, as the error amplification factor grows in an essentially exponential manner; therefore the routine must fail.

4. References

5. Parameters

1: \( X \) -- DOUBLE PRECISION Input
   On entry: the argument \( x \) of the function.

2: IFAIL -- INTEGER Input/Output
   On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
   On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL = 1
   On entry ABS(X) is too large for an accurate result to be returned. On soft failure, the routine returns zero.

7. Accuracy

Since the function is oscillatory, the absolute error rather than the relative error is important. Let \( E \) be the absolute error in the result and \( (\delta) \) be the relative error in the argument. If \( (\delta) \) is somewhat larger than the machine precision, then we have:

\[
\left| x \right| \ll \varepsilon
\]
\[ E^{-\frac{x}{\sqrt{2}}} = \frac{\delta}{\sqrt{2}} \]

(provided \( E \) is within machine bounds).

For small \( x \) the error amplification is insignificant and thus the absolute error is effectively bounded by the machine precision.

For medium and large \( x \), the error behaviour is oscillatory and

\[ \frac{1}{\sqrt{2}} \]

its amplitude grows like \( \frac{x}{\sqrt{2}} \). Therefore it is not possible to calculate the function with any accuracy when

\[ \frac{x}{\sqrt{2}} > \frac{\delta}{2\pi} \]

the minimum value of \( x \) for which the function overflows.

8. Further Comments

For details of the time taken by the routine see the Users' Note for your implementation.

9. Example

The example program reads values of the argument \( x \) from a file, evaluates the function at each value of \( x \) and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

S19 -- Approximations of Special Functions
S19ABF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose
S19ABF returns a value for the Kelvin function $\text{bei} \, x$ via the routine name.

2. Specification

```plaintext
DOUBLE PRECISION FUNCTION S19ABF (X, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X
```

3. Description

This routine evaluates an approximation to the Kelvin function $\text{bei} \, x$.

Note: $\text{bei}(-x)=\text{beix}$, so the approximation need only consider $x\geq 0.0$.

The routine is based on several Chebyshev expansions:

For $0\leq x \leq 5$,

\[
\text{bei} \, x = \sum_{r=0}^{4} a_r T_r(t), \quad t = 2^{(-r)} - 1;
\]

For $x > 5$,

\[
\text{bei} \, x = e^{x/\sqrt{2}} \left[ (1 - a(t)) \sin(\alpha) - b(t) \cos(\alpha) \right]
\]

\[
\times \left[ (1 - c(t)) \cos(\beta) - d(t) \sin(\beta) \right]
\]

\[
\sqrt{2\pi x}
\]

where $\alpha = \frac{\pi}{8}$, $\beta = \frac{\pi}{8}$.

and \( a(t), b(t), c(t), \) and \( d(t) \) are expansions in the variable
\[
t = \frac{-1}{x}.
\]

When \( x \) is sufficiently close to zero, the result is computed as
\[
\frac{2}{x} \sin(x) \approx -i.
\]
If this result would underflow, the result returned is
\[
\frac{4}{x} \sin(x) = 0.0.
\]

For large \( x \), there is a danger of the result being totally inaccurate, as the error amplification factor grows in an essentially exponential manner; therefore the routine must fail.

4. References

5. Parameters

1: \( X \) -- DOUBLE PRECISION
   Input
   On entry: the argument \( x \) of the function.

2: \( IFAIL \) -- INTEGER
   Input/Output
   On entry: \( IFAIL \) must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
   On exit: \( IFAIL = 0 \) unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

\( IFAIL = 1 \)
On entry \( \text{ABS}(X) \) is too large for an accurate result to be returned. On soft failure, the routine returns zero.

7. Accuracy

Since the function is oscillatory, the absolute error rather than the relative error is important. Let \( E \) be the absolute error in the function, and \( \Delta \) be the relative error in the argument. If \( \Delta \) is somewhat larger than the machine precision, then we have:
\[
\begin{array}{|c|c|}
\hline
x & E = -(-\text{ber} x + \text{bei} x)(\delta) \\
\hline
1 & 1 \\
\sqrt{2} & 1 \\
\hline
\end{array}
\]

(provided \( E \) is within machine bounds).

For small \( x \) the error amplification is insignificant and thus the absolute error is effectively bounded by the machine precision.

For medium and large \( x \), the error behaviour is oscillatory and

\[
\frac{x}{\sqrt{\pi}} \approx e^{-\frac{x}{\sqrt{2}}}.
\]

its amplitude grows like \( e^{-\frac{x}{\sqrt{2}}} \). Therefore it is

impossible to calculate the functions with any accuracy when

\[
\frac{x}{\sqrt{\pi}} > \frac{\delta}{\sqrt{\pi}}. \]

Note that this value of \( x \) is much smaller than the minimum value of \( x \) for which the function overflows.

8. Further Comments

For details of the time taken by the routine see the Users’ Note for your implementation.

9. Example

The example program reads values of the argument \( x \) from a file, evaluates the function at each value of \( x \) and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

---

S19 -- Approximations of Special Functions

S19ACF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.
1. Purpose

S19ACF returns a value for the Kelvin function \( \ker x \), via the routine name.

2. Specification

```plaintext
DOUBLE PRECISION FUNCTION S19ACF (X, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X
```

3. Description

This routine evaluates an approximation to the Kelvin function \( \ker x \).

Note: for \( x<0 \) the function is undefined and at \( x=0 \) it is infinite so we need only consider \( x>0 \).

The routine is based on several Chebyshev expansions:

For \( 0<x\leq1 \),

\[
\begin{align*}
\ker x &= -f(t) \log x + \frac{(\pi)^2}{16} x g(t) + y(t) \\
&\quad \text{where } f(t), g(t) \text{ and } y(t) \text{ are expansions in the variable } t=2x -1;
\end{align*}
\]

For \( 1<x\leq3 \),

\[
\begin{align*}
\ker x &= \exp(-\frac{11}{16}x)q(t) \\
&\quad \text{where } q(t) \text{ is an expansion in the variable } t=x-2;
\end{align*}
\]

For \( x>3 \),

\[
\begin{align*}
\ker x &= \frac{-x}{\sqrt{2x}} \left(\frac{1}{x} \right) \\
&\quad \text{where } e^{(x^2/4-1/16)} - [((1+(-c(t))\cos(beta))-d(t)\sin(beta)] \\
&\quad \text{with } \beta = \pi \text{ and } c(t), d(t) \text{ are expansions in the variable } t=x-2;
\end{align*}
\]
where \((\beta) = \ldots \), and \(c(t)\) and \(d(t)\) are expansions in the variable \(t = -1\).

When \(x\) is sufficiently close to zero, the result is computed as

\[
\text{ker } x = -(\gamma) - \log(\sqrt{-x}) + \log(\sqrt{2})
\]

and when \(x\) is even closer to zero, simply as

\[
\text{ker } x = -(\gamma) - \log(-)\sqrt{2}
\]

For large \(x\), \(\text{ker } x\) is asymptotically given by

\[
\sqrt{-x}\sqrt{\pi - \sqrt{2}}
\]

this becomes so small that it cannot be computed without underflow and the routine fails.

4. References

5. Parameters

1: \(X\) -- DOUBLE PRECISION Input
   On entry: the argument \(x\) of the function. Constraint: \(X > 0\).

2: \(IFAIL\) -- INTEGER Input/Output
   On entry: \(IFAIL\) must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

   On exit: \(IFAIL = 0\) unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:
IFAIL= 1
On entry X is too large, the result underflows. On soft failure, the routine returns zero.

IFAIL= 2
On entry X ≤ 0, the function is undefined. On soft failure the routine returns zero.

7. Accuracy

Let E be the absolute error in the result, (epsilon) be the relative error in the result and (delta) be the relative error in the argument. If (delta) is somewhat larger than the machine precision, then we have:

\[ \left| \frac{x}{\sqrt{2}} \right| E = \left| \frac{-\ker x + \kei x}{1 + 1} \right| (\delta), \]

\[ \left| \frac{\ker x + \kei x}{x + 1} \right| \]

\[ \left( \epsilon \right) = \left| \frac{-\ker x}{1 + 1} \right| (\delta). \]

For very small x, the relative error amplification factor is approximately given by

\[ \left| \frac{1}{\log x} \right| \]

which implies a strong attenuation of relative error. However, (epsilon) in general cannot be less than the machine precision.

For small x, errors are damped by the function and hence are limited by the machine precision.

For medium and large x, the error behaviour, like the function itself, is oscillatory, and hence only the absolute accuracy for the function can be maintained. For this range of x, the

\[ \frac{(\pi)x}{\sqrt{2}} \]

amplitude of the absolute error decays like

\[ \frac{-x}{\sqrt{2}} \]

which implies a strong attenuation of error. Eventually, ker x,

\[ \frac{-(\pi)}{\sqrt{2}} \]

which asymptotically behaves like

\[ \frac{-x}{\sqrt{2}} \]

becomes so
small that it cannot be calculated without causing underflow, and
the routine returns zero. Note that for large x the errors are
dominated by those of the Fortran intrinsic function EXP.

8. Further Comments

Underflow may occur for a few values of x close to the zeros of
ker x, below the limit which causes a failure with IFAIL = 1.

9. Example

The example program reads values of the argument x from a file,
evaluates the function at each value of x and prints the results.

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.

1. Purpose

S19ADF returns a value for the Kelvin function keix via the
routine name.

2. Specification

DOUBLE PRECISION FUNCTION S19ADF (X, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X

3. Description

This routine evaluates an approximation to the Kelvin function
keix.

Note: for x<0 the function is undefined, so we need only consider
x>=0.

The routine is based on several Chebyshev expansions:
For 0<=x<=1,
\[
keix = \frac{2}{4} \pi x \left[ f(t) + \frac{1}{4} [-g(t) \log x + v(t)] \right]
\]
where \( f(t), g(t), \) and \( v(t) \) are expansions in the variable \( t = 2x - 1 \);

For 1<x<=3,
\[
keix = \exp(-\frac{x}{4}) u(t)
\]
where \( u(t) \) is an expansion in the variable \( t = x - 2 \);

For x>3,
\[
keix = \sqrt{\frac{\pi}{2x}} \left( 1 + \frac{x}{\sqrt{2}} \right) c(t) \sin(\beta) + \frac{x}{\sqrt{2}} d(t) \cos(\beta)
\]
where \( \beta = \frac{\pi}{4} \), and \( c(t) \) and \( d(t) \) are expansions in the variable \( t = \frac{1}{x} - 1 \);

For x<0, the function is undefined, and hence the routine fails and returns zero.

When \( x \) is sufficiently close to zero, the result is computed as
\[
keix = \frac{2}{4} \pi x \left( 1 - \gamma - \log \frac{\pi}{2} \right)
\]
and when \( x \) is even closer to zero simply as
\[
keix = \frac{\pi}{4}.
\]
For large $x$, $\text{keix}$ is asymptotically given by $\frac{-x}{\sqrt{2}}$ and this becomes so small that it cannot be computed without underflow and the routine fails.

4. References

5. Parameters

1: X -- DOUBLE PRECISION Input
   On entry: the argument $x$ of the function. Constraint: $X \geq 0$.

2: IFAIL -- INTEGER Input/Output
   On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
   On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
   On entry $X$ is too large, the result underflows. On soft failure, the routine returns zero.

IFAIL= 2
   On entry $X < 0$, the function is undefined. On soft failure the routine returns zero.

7. Accuracy

Let $E$ be the absolute error in the result, and $(\delta)$ be the relative error in the argument. If $(\delta)$ is somewhat larger than the machine representation error, then we have:

$$\frac{|x|}{E} = (-\text{ker} x + \text{kei} x) |(\delta)|.$$
For small $x$, errors are attenuated by the function and hence are limited by the machine precision.

For medium and large $x$, the error behaviour, like the function itself, is oscillatory and hence only absolute accuracy of the function can be maintained. For this range of $x$, the amplitude of

$$\sqrt{\frac{\pi}{2}} x^{-\frac{1}{2}}$$

the absolute error decays like

$$\sqrt{\frac{\pi}{2}} e^{-x\sqrt{2}}$$

which implies a strong attenuation of error. Eventually, $ke^{ix}$, which is

$$\sqrt{\frac{\pi}{2}} e^{-x\sqrt{2}}$$

asymptotically given by

$$\sqrt{\frac{\pi}{2}} e^{-x\sqrt{2}}$$

becomes so small that it cannot be calculated without causing underflow and therefore the routine returns zero. Note that for large $x$, the errors are dominated by those of the Fortran intrinsic function EXP.

8. Further Comments

Underflow may occur for a few values of $x$ close to the zeros of $ke^{ix}$, below the limit which causes a failure with $IFAIL = 1$.

9. Example

The example program reads values of the argument $x$ from a file, evaluates the function at each value of $x$ and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%% S20 -- Approximations of Special Functions S20ACF
S20ACF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.
1. Purpose

S20ACF returns a value for the Fresnel Integral \( S(x) \), via the routine name.

2. Specification

```fortran
DOUBLE PRECISION FUNCTION S20ACF (X, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X
```

3. Description

This routine evaluates an approximation to the Fresnel Integral

\[
S(x) = \int_0^x \frac{\sin(t)}{\sqrt{\pi}} dt.
\]

Note: \( S(x) = -S(-x) \), so the approximation need only consider \( x \geq 0 \).

The routine is based on three Chebyshev expansions:

For \( 0 < x \leq 3 \),

\[
S(x) = \sum_{r=0}^{3} a_r T_4(t), \quad t = 2(x - 1) - 1
\]

For \( x > 3 \),

\[
S(x) = \frac{f(x)}{x^2} \cos\left(\frac{\pi}{2} x\right) - \frac{g(x)}{x^3} \sin\left(\frac{\pi}{2} x\right)
\]

where \( f(x) = \sum_{r=0}^{3} b_r T_4(t) \),

\[
T_4(t) = \frac{1}{\sqrt{2}} \left(2t^4 - 3t^2 + 1\right)
\]

and \( g(x) = \sum_{r=0}^{3} c_r T_4(t) \) with \( t = 2(x - 1) - 1 \).
CHAPTER 15. CHAPTER N

For small $x$, $S(x) \approx \frac{1}{x}$. This approximation is used when $x$ is sufficiently small for the result to be correct to machine precision. For very small $x$, this approximation would underflow; the result is then set exactly to zero.

$$\frac{1}{\pi}$$

For large $x$, $f(x) \approx \frac{1}{2}$ and $g(x) \approx \frac{1}{2}$. Therefore for $$\frac{1}{\pi}$$

moderately large $x$, when $\frac{1}{2}$ is negligible compared with $\frac{-1}{\pi x}$, the second term in the approximation for $x > 3$ may be dropped. For very large $x$, when $\frac{1}{\pi x}$ becomes negligible, $S(x) \approx \frac{1}{2}$. However, there will be considerable difficulties in calculating $\cos\left(\frac{\pi}{2}x\right)$ accurately before this final limiting value can be used. Since $\cos\left(\frac{\pi}{2}x\right)$ is periodic, its value is essentially determined by the fractional part of $x$. If $x = N + (\theta)$ where $N$ is an integer and $0 \leq \theta < 1$, then $\cos\left(\frac{\pi}{2}x\right)$ depends on $(\theta)$ and on $N$ modulo 4. By exploiting this fact, it is possible to retain significance in the calculation of $\cos\left(\frac{\pi}{2}x\right)$ either all the way to the very large $x$ limit, or at least until the integer part of $\frac{x}{2}$ is equal to the maximum integer allowed on the machine.

4. References

5. Parameters

1: $X$ -- DOUBLE PRECISION

Input

On entry: the argument $x$ of the function.
2: IFAIL -- INTEGER
     Input/Output
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.
     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

There are no failure exits from this routine. The parameter IFAIL
has been included for consistency with other routines in this
chapter.

7. Accuracy

Let (delta) and (epsilon) be the relative errors in the argument
and result respectively.

If (delta) is somewhat larger than the machine precision (i.e.,
if (delta) is due to data errors etc), then (epsilon) and (delta)
are approximately related by:

\[ (\text{epsilon}) \approx \frac{(\pi) \ 2}{S(x)} \cdot (\text{delta}) \]

Figure 1 shows the behaviour of the error amplification factor

\[ \frac{(\pi) \ 2}{S(x)} \]

However if (delta) is of the same order as the machine precision,
then rounding errors could make (epsilon) slightly larger than
the above relation predicts.

For small x, (epsilon) \approx 3(delta) and hence there is only moderate
amplification of relative error. Of course for very small x where
the correct result would underflow and exact zero is returned,
relative error-control is lost.
For moderately large values of $x$,
\[
| (\pi/2) | = 2x \sin\left(\frac{\pi}{2}x\right) |(\text{delta})| \\
| (2) |
\]
and the result will be subject to increasingly large amplification of errors. However the above relation breaks down for large values of $x$ (i.e., when $x$ is of the order of the machine precision in this region the relative error in the result is essentially bounded by $\frac{x}{(\pi)x}$).

Hence the effects of error amplification are limited and at worst the relative error loss should not exceed half the possible number of significant figures.

8. Further Comments
None.

9. Example

The example program reads values of the argument $x$ from a file, evaluates the function at each value of $x$ and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
DOUBLE PRECISION FUNCTION S20ADF (X, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X

3. Description
This routine evaluates an approximation to the Fresnel Integral
\[
C(x) = \int_0^x \frac{\cos\left(\frac{t}{\sqrt{2}}\right) dt}{\left(\frac{\pi}{2}\right)}
\]

Note: \( C(x) = -C(-x) \), so the approximation need only consider \( x \geq 0.0 \)

The routine is based on three Chebyshev expansions:

For \( 0 < x \leq 3 \),
\[
C(x) = x^4 \sum_{r=0}^{(3)} a_r T_r(t), \quad t = 2(\sqrt{2} - 1) - 1
\]

For \( x > 3 \),
\[
C(x) = \sum_{r=0}^{(3)} \left( \frac{1}{\pi^2} \right)^{1/2} \frac{1}{\sqrt{x}} f(x) + \frac{1}{\pi^2} \frac{1}{\sqrt{x}} g(x)
\]
where
\[
f(x) = \sum_{r=0}^{(3)} b_r T_r(t), \quad t = 2(\sqrt{2} - 1) - 1
\]
and
\[
g(x) = \sum_{r=0}^{(3)} c_r T_r(t), \quad t = 2(\sqrt{2} - 1) - 1
\]

For small \( x \), \( C(x) \approx x \). This approximation is used when \( x \) is sufficiently small for the result to be correct to machine precision.

For large \( x \), \( f(x) \approx \frac{1}{\pi^2} \) and \( g(x) \approx \frac{1}{\pi^2} \frac{1}{\sqrt{2}} \). Therefore for
\[
\left(\frac{\pi}{2}\right)
\]
moderately large $x$, when \( \frac{1}{2^3} \) is negligible compared with \( \frac{1}{2} \), the second term in the approximation for $x > 3$ may be dropped. For very large $x$, when \( \frac{1}{\pi x} \) becomes negligible, $C(x) \approx -\frac{1}{2}$. However there will be considerable difficulties in calculating \( \sin\left(\frac{\pi}{2}x\right) \) accurately before this final limiting value can be used. Since $\sin\left(\frac{\pi}{2}x\right)$ is periodic, its value is essentially determined by the fractional part of $x$. If $x = N + \theta$, where $N$ is an integer and $0 \leq \theta < 1$, then $\sin\left(\frac{\pi}{2}x\right)$ depends on $(\frac{\pi}{2})$ $(\theta)$ and on $N$ modulo 4. By exploiting this fact, it is possible to retain some significance in the calculation of \( \sin\left(\frac{\pi}{2}x\right) \) either all the way to the very large $x$ limit, or at least until the integer part of $\frac{x}{2}$ is equal to the maximum integer allowed on the machine.

4. References

5. Parameters

1: $X$ -- DOUBLE PRECISION
   On entry: the argument $x$ of the function.

2: $IFAIL$ -- INTEGER
   On entry: $IFAIL$ must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
   On exit: $IFAIL = 0$ unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings
There are no failure exits from this routine. The parameter IFAIL has been included for consistency with other routines in this chapter.

7. Accuracy

Let (delta) and (epsilon) be the relative errors in the argument and result respectively.

If (delta) is somewhat larger than the machine precision (i.e. if (delta) is due to data errors etc), then (epsilon) and (delta) are approximately related by:

\[
| \frac{(\pi/2) \cos(\pi/2 - x)}{C(x)} | (\text{epsilon}) \approx \frac{\text{(delta)}}{C(x)}.
\]

Figure 1 shows the behaviour of the error amplification factor

\[
| \frac{(\pi/2) \cos(\pi/2 - x)}{C(x)} | (\text{epsilon}) = |2x \cos(\pi/2 - x)| (\text{delta}).
\]

However if (delta) is of the same order as the machine precision, then rounding errors could make (epsilon) slightly larger than the above relation predicts.

For small x, (epsilon) \approx (delta) and there is no amplification of relative error.

For moderately large values of x,

\[
| \frac{(\pi/2) \cos(\pi/2 - x)}{C(x)} | (\text{epsilon}) \approx |2x \cos(\pi/2 - x)| (\text{delta}).
\]

and the result will be subject to increasingly large amplification of errors. However the above relation breaks down for large values of x (i.e., when \( \frac{x}{2} \) is of the order of the machine precision).
machine precision); in this region the relative error in the
result is essentially bounded by \( \frac{\pi x}{2} \).

Hence the effects of error amplification are limited and at worst
the relative error loss should not exceed half the possible
number of significant figures.

8. Further Comments
None.

9. Example
The example program reads values of the argument \( x \) from a file,
evaluates the function at each value of \( x \) and prints the results.

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.
\[
\frac{1}{dt} \quad R(x, y) = -\frac{1}{C} \quad \frac{1}{2} \quad \sqrt{\int_{t+x(t+y)}^{y}}
\]

where \( x \geq 0 \) and \( y \neq 0 \).

This function, which is related to the logarithm or inverse hyperbolic functions for \( y \leq x \) and to inverse circular functions if \( x \leq y \), arises as a degenerate form of the elliptic integral of the first kind. If \( y < 0 \), the result computed is the Cauchy principal value of the integral.

The basic algorithm, which is due to Carlson [2] and [3], is to reduce the arguments recursively towards their mean by the system:

\[
\begin{align*}
x &= x, \\
y &= y, \\
(\mu) &= (x + 2y) / 3, \\
S &= (y - x) / 3(\mu). \\
\end{align*}
\]

\[
(\lambda) = y + 2 \sqrt{x y} \\
x &= (x + (\lambda)) / 4, \\
y &= (y + (\lambda)) / 4. \\
\]

The quantity \(|S|\) for \( n=0, 1, 2, 3, \ldots \) decreases with increasing \( n \), eventually \(|S| \sim 1/4 \). For small enough \( S \) the required function value can be approximated by the first few terms of the Taylor series about the mean. That is

\[
\begin{pmatrix}
2 & 3 & 4 & 5 \\
3S & S & 3S & 9S
\end{pmatrix}
\]
\[ R(x,y) = \frac{1}{10} + \frac{1}{7} + \frac{1}{8} + \frac{1}{22} \]

The truncation error involved in using this approximation is bounded by \(16|S|/(1-2|S|)\) and the recursive process is stopped when \(S\) is small enough for this truncation error to be negligible compared to the machine precision.

Within the domain of definition, the function value is itself representable for all representable values of its arguments. However, for values of the arguments near the extremes the above algorithm must be modified so as to avoid causing underflows or overflows in intermediate steps. In extreme regions arguments are pre-scaled away from the extremes and compensating scaling of the result is done before returning to the calling program.

4. References

5. Parameters

1: X -- DOUBLE PRECISION Input

2: Y -- DOUBLE PRECISION Input

On entry: the arguments x and y of the function, respectively. Constraint: \(X \geq 0.0\) and \(Y \neq 0.0\).

3: IFAIL -- INTEGER Input/Output

On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings
Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1
On entry X < 0.0; the function is undefined.

IFAIL= 2
On entry Y = 0.0; the function is undefined.

On soft failure the routine returns zero.

7. Accuracy

In principle the routine is capable of producing full machine precision. However round-off errors in internal arithmetic will result in slight loss of accuracy. This loss should never be excessive as the algorithm does not involve any significant amplification of round-off error. It is reasonable to assume that the result is accurate to within a small multiple of the machine precision.

8. Further Comments

Users should consult the Chapter Introduction which shows the relationship of this function to the classical definitions of the elliptic integrals.

9. Example

This example program simply generates a small set of non-extreme arguments which are used with the routine to produce the table of low accuracy results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
S21BBF returns a value of the symmetrised elliptic integral of the first kind, via the routine name.

2. Specification

DOUBLE PRECISION FUNCTION S21BBF (X, Y, Z, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X, Y, Z

3. Description

This routine calculates an approximation to the integral

\[
\int_{1}^{\infty} \frac{dt}{F^2 / \sqrt{(t+x)(t+y)(t+z)}}
\]

where \( x, y, z \geq 0 \) and at most one is zero.

The basic algorithm, which is due to Carlson \[2\] and \[3\], is to reduce the arguments recursively towards their mean by the rule:

\[
x = \min(x, y, z), \quad z = \max(x, y, z),
\]

\[
y = \text{remaining third intermediate value argument}.
\]

(This ordering, which is possible because of the symmetry of the function, is done for technical reasons related to the avoidance of overflow and underflow.)

\[
(mu) = \frac{x + y + 3z}{3}
\]

\[
X = \frac{(1-x)/(mu)}
\]

\[
Y = \frac{(1-y)/(mu)}
\]

\[
Z = \frac{(1-z)/(mu)}
\]

\[
(lambda) = \sqrt{xy + yz + zx}
\]
\[
x = \frac{(x + \lambda)}{4}
\]
\[
y = \frac{(y + \lambda)}{4}
\]
\[
z = \frac{(z + \lambda)}{4}
\]

\[
(\epsilon) = \max(|X|,|Y|,|Z|)
\]

and the function may be approximated adequately by a 5th order power series:

\[
R(x,y,z) = \frac{1}{(1- \frac{E}{10} - \frac{E}{24} - \frac{E}{44} - \frac{E}{14})}
\]

where \( E = X Y + Y Z + Z X \), \( E = X Y Z \).

The truncation error involved in using this approximation is bounded by \( \frac{\epsilon}{4(1-(\epsilon))} \) and the recursive process is stopped when this truncation error is negligible compared with the machine precision.

Within the domain of definition, the function value is itself representable for all representable values of its arguments. However, for values of the arguments near the extremes the above algorithm must be modified so as to avoid causing underflows or overflows in intermediate steps. In extreme regions arguments are pre-scaled away from the extremes and compensating scaling of the result is done before returning to the calling program.

4. References

CHAPTER 15. CHAPTER N

5. Parameters

1: X -- DOUBLE PRECISION Input
2: Y -- DOUBLE PRECISION Input
3: Z -- DOUBLE PRECISION Input
   On entry: the arguments x, y and z of the function.
   Constraint: X, Y, Z >= 0.0 and only one of X, Y and Z may be zero.
4: IFAIL -- INTEGER Input/Output
   On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
   On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1
   On entry one or more of X, Y and Z is negative; the function is undefined.

IFAIL= 2
   On entry two or more of X, Y and Z are zero; the function is undefined.

   On soft failure, the routine returns zero.

7. Accuracy

In principle the routine is capable of producing full machine precision. However round-off errors in internal arithmetic will result in slight loss of accuracy. This loss should never be excessive as the algorithm does not involve any significant amplification of round-off error. It is reasonable to assume that the result is accurate to within a small multiple of the machine precision.

8. Further Comments
Users should consult the Chapter Introduction which shows the relationship of this function to the classical definitions of the elliptic integrals.

If two arguments are equal, the function reduces to the elementary integral \( R \), computed by \texttt{S21BAF}.

9. Example

This example program simply generates a small set of non-extreme arguments which are used with the routine to produce the table of low accuracy results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

---

**S21 -- Approximations of Special Functions**

\texttt{S21BCF} -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

\texttt{S21BCF} returns a value of the symmetrised elliptic integral of the second kind, via the routine name.

2. Specification

\begin{verbatim}
DOUBLE PRECISION FUNCTION S21BCF (X, Y, Z, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X, Y, Z
\end{verbatim}

3. Description

This routine calculates an approximate value for the integral

\[
\int_{D}^{\infty} \frac{dt}{\sqrt{(t+x)(t+y)(t+z)}}
\]

\( D \) is

3 / 2 / 3
\[
R(x,y,z) = - \int_{D}^{\infty} \frac{dt}{\sqrt{(t+x)(t+y)(t+z)}}
\]

\[
\int_{D}^{\infty} \frac{dt}{\sqrt{(t+x)(t+y)(t+z)}}
\]
where \( x, y \geq 0 \), at most one of \( x \) and \( y \) is zero, and \( z > 0 \).

The basic algorithm, which is due to Carlson [2] and [3], is to reduce the arguments recursively towards their mean by the rule:

\[
\begin{align*}
   x &= x^0 \\
   y &= y^0 \\
   z &= z^0 \\
   (\mu) &= (x + y + 3z) / 5 \\
   X &= (1-x)/(\mu) \\
   Y &= (1-y)/(\mu) \\
   Z &= (1-z)/(\mu) \\
   (\lambda) &= (x/y + y/z + z/x) \\
   x &= (x + (\lambda)) / 4 \\
   y &= (y + (\lambda)) / 4 \\
   z &= (z + (\lambda)) / 4 \\

\end{align*}
\]

For \( n \) sufficiently large,

\[
\begin{align*}
   (\epsilon) &= \max(|X|, |Y|, |Z|) / n \\
   (\epsilon) &= \max(|X|, |Y|, |Z|) / n \\

\end{align*}
\]

and the function may be approximated adequately by a 5th order

\[
\begin{align*}
   (-1)^n \\
   \lambda = \max(|X|, |Y|, |Z|)^4 \\

\end{align*}
\]
power series \( R(x,y,z)=\frac{3}{\sqrt{D}} \)

\[ \sum_{m=0}^{\infty} \frac{(z+(\lambda))^m}{z^m} + \frac{4}{7n} \left[ \frac{3}{n} \right. \left. + \frac{1}{3n} + \frac{1}{3n} + \frac{1}{3n} + \frac{1}{n} + \frac{1}{n} + \frac{1}{n} + \frac{1}{n} \right] \]

\[ \cdot \frac{1}{1-(\epsilon)} \logo{\mu n} \]

where

\( (m) = \binom{m}{n} \)

\( S = \frac{x+y+3z}{2m} \)

The truncation error in this expansion is bounded by

\[ \frac{6 \epsilon}{\sqrt{n}} \]

and the recursive process is terminated when

\[ \frac{3}{1-(\epsilon)} \]

this quantity is negligible compared with the machine precision.

The routine may fail either because it has been called with arguments outside the domain of definition, or with arguments so extreme that there is an unavoidable danger of setting underflow or overflow.

\[-\frac{3}{2}\]

Note: \( R(x,x,x) = x \), so there exists a region of extreme arguments for which the function value is not representable.

4. References

5. Parameters

1: X -- DOUBLE PRECISION Input
2: Y -- DOUBLE PRECISION Input
3: Z -- DOUBLE PRECISION Input
   On entry: the arguments x, y and z of the function.
   Constraint: X, Y >= 0.0, Z > 0.0 and only one of X and Y may be zero.
4: IFAIL -- INTEGER Input/Output
   On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
   On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL = 1
   On entry either X or Y is negative, or both X and Y are zero; the function is undefined.

IFAIL = 2
   On entry Z <= 0.0; the function is undefined.

IFAIL = 3
   On entry either Z is too close to zero or both X and Y are too close to zero: there is a danger of setting overflow.

IFAIL = 4
   On entry at least one of X, Y and Z is too large: there is a danger of setting underflow.

   On soft failure the routine returns zero.

7. Accuracy

In principle the routine is capable of producing full machine
precision. However round-off errors in internal arithmetic will result in slight loss of accuracy. This loss should never be excessive as the algorithm does not involve any significant amplification of round-off error. It is reasonable to assume that the result is accurate to within a small multiple of the machine precision.

8. Further Comments

Users should consult the Chapter Introduction which shows the relationship of this function to the classical definitions of the elliptic integrals.

9. Example

This example program simply generates a small set of non-extreme arguments which are used with the routine to produce the table of low accuracy results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
S21 -- Approximations of Special Functions
S21 -- NAG Foundation Library Routine Document
Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S21BDF returns a value of the symmetrised elliptic integral of the third kind, via the routine name.

2. Specification

```plaintext
DOUBLE PRECISION FUNCTION S21BDF (X, Y, Z, R, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X, Y, Z, R
```

3. Description

This routine calculates an approximation to the integral

\[
\int_{0}^{\infty} \frac{3}{t} \, dt
\]
\[
R(x,y,z,(\rho)) = - \int_0^2 \frac{\sqrt{t+\rho}}{(t+x)(t+y)(t+z)} dt
\]

where \( x, y, z \geq 0 \), \( \rho \neq 0 \) and at most one of \( x, y \) and \( z \) is zero.

If \( p < 0 \), the result computed is the Cauchy principal value of the integral.

The basic algorithm, which is due to Carlson \[2\] and \[3\], is to reduce the arguments recursively towards their mean by the rule:

\[
x = x_0
\]

\[
y = y_0
\]

\[
z = z_0
\]

\[
(\rho) = (\rho)_0
\]

\[
(\mu) = \frac{(x+y+z+2(\rho))}{5}
\]

\[
X = \frac{1-x}{(\mu)}
\]

\[
Y = \frac{1-y}{(\mu)}
\]

\[
Z = \frac{1-z}{(\mu)}
\]

\[
P = \frac{1-(\rho)}{(\mu)}
\]

\[
(\lambda) = \frac{x+y+z+2(\rho)}{4}
\]

\[
x = \frac{(x+\lambda)}{4}
\]

\[
y = \frac{(y+\lambda)}{4}
\]
\[
\begin{align*}
\frac{z}{n+1} &= \frac{z + (\lambda)}{4} \\
\frac{\rho}{n+1} &= \frac{(\rho) + (\lambda)}{4} \\
\frac{\alpha}{n} &= \left[ \frac{\rho}{n} \right] \frac{1}{n} + \frac{\rho}{n} + \frac{\rho}{n} + \frac{\rho}{n} + \frac{\rho}{n} \\
\frac{\beta}{n} &= \frac{(\rho) + (\lambda) + (\lambda)}{n} \\
\end{align*}
\]

For \( n \) sufficiently large,

\[
\epsilon = \max(\frac{|X|}{n}, |Y|, |Z|, |P|)^{\frac{1}{4}}
\]

and the function may be approximated by a 5th order power series

\[
R(x, y, z, \rho) = \sum_{m=0}^{n-1} \frac{a_m}{4^m} (\alpha) (\beta)
\]

where \( a_m = \frac{(X + Y + Z + 2P)}{2^m} \).

The truncation error in this expansion is bounded by

\[
\epsilon \leq \frac{3}{6} \epsilon (1 - \epsilon) \quad \text{and the recursion process is terminated when this quantity is negligible compared with the machine precision. The routine may fail either because it has been called with arguments outside the domain of definition or}
\]
with arguments so extreme that there is an unavoidable danger of
setting underflow or overflow.

\[ \begin{align*}
3 \\
-2
\end{align*} \]

Note: \( R(x,x,x,x) = x \), so there exists a region of extreme values
for which the function value is not representable.

4. References

Functions. Dover Publications.

5. Parameters

1: \( X \) -- DOUBLE PRECISION Input
2: \( Y \) -- DOUBLE PRECISION Input
3: \( Z \) -- DOUBLE PRECISION Input
4: \( R \) -- DOUBLE PRECISION Input
On entry: the arguments \( x, y, z \) and (rho) of the function.
Constraint: \( X, Y, Z \geq 0.0, R \neq 0.0 \) and at most one of \( X, Y \) and \( Z \) may be zero.

5: \( IFAIL \) -- INTEGER Input/Output
On entry: \( IFAIL \) must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential
Introduction) the recommended value is 0.
On exit: \( IFAIL = 0 \) unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry \( IFAIL = 0 \) or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).
IFAIL = 1
On entry at least one of X, Y and Z is negative, or at least
two of them are zero; the function is undefined.

IFAIL = 2
On entry R = 0.0; the function is undefined.

IFAIL = 3
On entry either R is too close to zero, or any two of X, Y
and Z are too close to zero; there is a danger of setting
overflow.

IFAIL = 4
On entry at least one of X, Y, Z and R is too large; there
is a danger of setting underflow.

IFAIL = 5
An error has occurred in a call to S21BAF. Any such
occurrence should be reported to NAG.

On soft failure, the routine returns zero.

7. Accuracy

In principle the routine is capable of producing full machine
precision. However round-off errors in internal arithmetic will
result in slight loss of accuracy. This loss should never be
excessive as the algorithm does not involve any significant
amplification of round-off error. It is reasonable to assume that
the result is accurate to within a small multiple of the machine
precision.

8. Further Comments

Users should consult the Chapter Introduction which shows the
relationship of this function to the classical definitions of the
elliptic integrals.

If the argument R is equal to any of the other arguments, the
function reduces to the integral R , computed by S21BCF.

9. Example

This example program simply generates a small set of non-extreme
arguments which are used with the routine to produce the table of
low accuracy results.

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation Library software and should be available on-line.

++ s13adf(x,ifail)
++ returns the value of the sine integral
++ See \downlink{Manual Page}{manpageXXs13adf}.
s14aaf : (DoubleFloat,Integer) -> Result
++ s14aaf(x,ifail) returns the value of the Gamma function Gamma(x),
++ via the routine name.
++ See \downlink{Manual Page}{manpageXXs14aaf}.
s14abf : (DoubleFloat,Integer) -> Result
++ s14abf(x,ifail) returns a value for the log, \ln(Gamma(x)), via
++ the routine name.
++ See \downlink{Manual Page}{manpageXXs14abf}.
s14abf : (DoubleFloat,DoubleFloat,DoubleFloat,Integer) -> Result
++ s14abf(a,x,tol,ifail)
++ computes values for the incomplete gamma functions P(a,x)
++ and Q(a,x).
++ See \downlink{Manual Page}{manpageXXs14abf}.
s15adf : (DoubleFloat,Integer) -> Result
++ s15adf(x,ifail)
++ returns the value of the complementary error function,
++ erfc(x), via the routine name.
++ See \downlink{Manual Page}{manpageXXs15adf}.
s15aef : (DoubleFloat,Integer) -> Result
++ s15aef(x,ifail)
++ returns the value of the error function erf(x), via the
++ routine name.
++ See \downlink{Manual Page}{manpageXXs15aef}.
s17acf : (DoubleFloat,Integer) -> Result
++ s17acf(x,ifail)
++ returns the value of the Bessel Function
++ Y(x), via the routine name.
++ 0
++ See \downlink{Manual Page}{manpageXXs17acf}.
s17adf : (DoubleFloat,Integer) -> Result
++ s17adf(x,ifail)
++ returns the value of the Bessel Function
++ Y(x), via the routine name.
++ 1
++ See \downlink{Manual Page}{manpageXXs17adf}.
s17aef : (DoubleFloat,Integer) -> Result
++ s17aef(x,ifail)
++ returns the value of the Bessel Function
++ J \(x\), via the routine name.
++ 0
++ See \downlink{Manual Page}{manpageXXs17aef}.
s17aff : (DoubleFloat,Integer) -> Result
++ s17aff(x,ifail)
++ returns the value of the Bessel Function
++ J \(x\), via the routine name.
++ 1
++ See \downlink{Manual Page}{manpageXXs17aff}.
s17agf : (DoubleFloat,Integer) -> Result
++ s17agf(x,ifail)
++ returns a value for the Airy function, Ai\(x\), via the
++ routine name.
++ See \downlink{Manual Page}{manpageXXs17agf}.
s17ahf : (DoubleFloat,Integer) -> Result
++ s17ahf(x,ifail)
++ returns a value of the Airy function, Bi\(x\), via the
++ routine name.
++ See \downlink{Manual Page}{manpageXXs17ahf}.
s17ajf : (DoubleFloat,Integer) -> Result
++ s17ajf(x,ifail)
++ returns a value of the derivative of the Airy function
++ Ai\(x\), via the routine name.
++ See \downlink{Manual Page}{manpageXXs17ajf}.
s17akf : (DoubleFloat,Integer) -> Result
++ s17akf(x,ifail)
++ returns a value for the derivative of the Airy function
++ Bi\(x\), via the routine name.
++ See \downlink{Manual Page}{manpageXXs17akf}.
s17dcf : (DoubleFloat,Complex DoubleFloat,Integer,String,_
    Integer) -> Result
++ s17dcf(fnu,z,n,scale,ifail)
++ returns a sequence of values for the Bessel functions
++ Y \(z\) for complex \(z\), non-negative \(nu\) and \(n=0,1,...,N-1\),
++ \(nu+n\)
++ with an option for exponential scaling.
++ See \downlink{Manual Page}{manpageXXs17dcf}.
s17def : (DoubleFloat,Complex DoubleFloat,Integer,String,_
    Integer) -> Result
++ s17def(fnu,z,n,scale,ifail)
++ returns a sequence of values for the Bessel functions
++ J \(z\) for complex \(z\), non-negative \(nu\) and \(n=0,1,...,N-1\),
++ \(nu+n\)
++ with an option for exponential scaling.
++ See \downlink{Manual Page}{manpageXXs17def}.
s17dgf : (String,Complex DoubleFloat,String,Integer) -> Result
++ s17dgf(deriv,z,scale,ifail)
++ returns the value of the Airy function Ai(z) or its
++ derivative Ai'(z) for complex z, with an option for exponential
++ scaling.
++ See \downlink{Manual Page}{manpageXXs17dgf}.
s17dhf : (String,Complex DoubleFloat,String,Integer) -> Result
++ s17dhf(deriv,z,scale,ifail)
++ returns the value of the Airy function Bi(z) or its
++ derivative Bi'(z) for complex z, with an option for exponential
++ scaling.
++ See \downlink{Manual Page}{manpageXXs17dhf}.
s17dlf : (Integer,DoubleFloat,Complex DoubleFloat,Integer,_
String,Integer) -> Result
++ s17dlf(m,fnu,z,n,scale,ifail)
++ returns a sequence of values for the Hankel functions
++ (1) (2)
++ H (z) or H (z) for complex z, non-negative (nu) and
++ (nu)+n (nu)+n
++ n=0,1,...,N-1, with an option for exponential scaling.
++ See \downlink{Manual Page}{manpageXXs17dlf}.
s18acf : (DoubleFloat,Integer) -> Result
++ s18acf(x,ifail)
++ returns the value of the modified Bessel Function
++ K (x), via the routine name.
++ 0
++ See \downlink{Manual Page}{manpageXXs18acf}.
s18adf : (DoubleFloat,Integer) -> Result
++ s18adf(x,ifail)
++ returns the value of the modified Bessel Function
++ K (x), via the routine name.
++ 1
++ See \downlink{Manual Page}{manpageXXs18adf}.
s18aef : (DoubleFloat,Integer) -> Result
++ s18aef(x,ifail)
++ returns the value of the modified Bessel Function
++ I (x), via the routine name.
++ 0
++ See \downlink{Manual Page}{manpageXXs18aef}.
s18aff : (DoubleFloat,Integer) -> Result
++ s18aff(x,ifail)
++ returns a value for the modified Bessel Function
++ I (x), via the routine name.
++ 1
++ See \downlink{Manual Page}{manpageXXs18aff}.
s18dcf : (DoubleFloat,Complex DoubleFloat,Integer,String,_
Integer) -> Result
++ s18dcf(fnu,z,n,scale,ifail)
++ returns a sequence of values for the modified Bessel functions
++ K (z) for complex z, non-negative (nu) and
++ (nu)+n
++ n=0,1,...,N-1, with an option for exponential scaling.
++ See `downlink{Manual Page}{manpageXXs18dcf}.

s18def : (DoubleFloat,Complex DoubleFloat,Integer,String,_
  Integer) -> Result
++ s18def(fnu,z,n,scale,ifail)
++ returns a sequence of values for the modified Bessel functions
++ I (z) for complex z, non-negative (nu) and
++ (nu)+n
++ n=0,1,...,N-1, with an option for exponential scaling.
++ See `downlink{Manual Page}{manpageXXs18def}.
s19aaf : (DoubleFloat,Integer) -> Result
++ s19aaf(x,ifail)
++ returns a value for the Kelvin function ber(x) via the
++ routine name.

++ See `downlink{Manual Page}{manpageXXs19aaf}.
s19abf : (DoubleFloat,Integer) -> Result
++ s19abf(x,ifail)
++ returns a value for the Kelvin function bei(x) via the
++ routine name.

++ See `downlink{Manual Page}{manpageXXs19abf}.
s19acf : (DoubleFloat,Integer) -> Result
++ s19acf(x,ifail)
++ returns a value for the Kelvin function ker(x), via the
++ routine name.

++ See `downlink{Manual Page}{manpageXXs19acf}.
s19adf : (DoubleFloat,Integer) -> Result
++ s19adf(x,ifail)
++ returns a value for the Kelvin function kei(x) via the
++ routine name.

++ See `downlink{Manual Page}{manpageXXs19adf}.
s20acf : (DoubleFloat,Integer) -> Result
++ s20acf(x,ifail)
++ returns a value for the Fresnel Integral S(x), via the
++ routine name.

++ See `downlink{Manual Page}{manpageXXs20acf}.
s20adf : (DoubleFloat,Integer) -> Result
++ s20adf(x,ifail)
++ returns a value for the Fresnel Integral C(x), via the
++ routine name.

++ See `downlink{Manual Page}{manpageXXs20adf}.
s21baf : (DoubleFloat,DoubleFloat,Integer) -> Result
++ s21baf(x,y,ifail)
++ returns a value of an elementary integral, which occurs as
++ a degenerate case of an elliptic integral of the first kind, via
++ the routine name.

++ See `downlink{Manual Page}{manpageXXs21baf}.
s21bbf : (DoubleFloat,DoubleFloat,DoubleFloat,Integer) -> Result
++ s21bbf(x,y,z,ifail)
++ returns a value of the symmetrised elliptic integral of
++ the first kind, via the routine name.
++ See \downlink{Manual Page}{manpageXXs21bbf}.
s21bcf : (DoubleFloat,DoubleFloat,DoubleFloat,Integer) -> Result
++ s21bcf(x,y,z,ifail)
++ returns a value of the symmetrised elliptic integral of
++ the second kind, via the routine name.
++ See \downlink{Manual Page}{manpageXXs21bcf}.
s21bdf : (DoubleFloat,DoubleFloat,DoubleFloat,DoubleFloat,Integer) -> Result
++ s21bdf(x,y,z,r,ifail)
++ returns a value of the symmetrised elliptic integral of
++ the third kind, via the routine name.
++ See \downlink{Manual Page}{manpageXXs21bdf}.

--R----------------------------------------------------------- Operations ---------------
This package is a suite of functions for the numerical integration of an ordinary differential equation of n variables:

\[ \frac{dy}{dx} = f(y,x) \quad y \text{ is an n-vector} \]

All the routines are based on a 4-th order Runge-Kutta kernel.

These routines generally have as arguments:

- n, the number of dependent variables;
- x1, the initial point;
- h, the step size;
- y, a vector of initial conditions of length n

which upon exit contains the solution at x1 + h

derivs, a function which computes the right hand side of the ordinary differential equation:

\[ \text{derivs(dydx,y,x)} \]

computes dydx, a vector which contains the derivative information.

In order of increasing complexity:

- \text{rk4(y,n,x1,h,derivs)}

advances the solution vector to
and return the values in $y$.

$$\text{rk4}(y,n,x1,h,\text{derivs},t1,t2,t3,t4)$$

is the same as

$$\text{rk4}(y,n,x1,h,\text{derivs})$$

except that you must provide 4 scratch arrays $t1$-$t4$ of size $n$

Starting with $y$ at $x1$,

$$\text{rk4f}(y,n,x1,x2,ns,\text{derivs})$$

uses $ns$ fixed steps of a 4-th order Runge-Kutta integrator to advance the solution vector to $x2$ and return the values in $y$. Argument $x2$, is the final point, and $ns$, the number of steps to take.

$$\text{rk4qc}(y,n,x1,\text{step},\text{eps},\text{yscal},\text{derivs})$$

takes a 5-th order Runge-Kutta step with monitoring of local truncation to ensure accuracy and adjust stepsize.

The function takes two half steps and one full step and scales the difference in solutions at the final point. If the error is within $\text{eps}$, the step is taken and the result is returned.

If the error is not within $\text{eps}$, the stepsize if decreased and the procedure is tried again until the desired accuracy is reached. Upon input, an trial step size must be given and upon return, an estimate of the next step size to use is returned as well as the step size which produced the desired accuracy.

The scaled error is computed as

$$\text{error} = \text{MAX}(\text{ABS}((y2\text{steps}(i) - y1\text{step}(i))/\text{yscal}(i)))$$

and this is compared against $\text{eps}$. If this is greater than $\text{eps}$, the step size is reduced accordingly to

$$h\text{new} = 0.9 * h\text{did} * (\text{error}/\text{eps})^{(-1/4)}$$

If the error criterion is satisfied, then we check if the step size was too fine and return a more efficient one. If

$$\text{error} > \text{eps} * (6.0\text{E}-04)$$
then the next step size should be

\[ h_{\text{next}} = 0.9 \times h_{\text{did}} \times (\text{error}/\text{eps})^{-1/5} \]

Otherwise

\[ h_{\text{next}} = 4.0 \times h_{\text{did}} \]

is returned.

A more detailed discussion of this and related topics can be found in the book "Numerical Recipies" by W. Press, B. P. Flannery, S. A. Teukolsky, W. T. Vetterling published by Cambridge University Press.

Argument step is a record of 3 floating point numbers (try, did, next), eps is the required accuracy, yscal is the scaling vector for the difference in solutions.

On input, step.try should be the guess at a step size to achieve the accuracy. On output, step.did contains the step size which achieved the accuracy and step.next is the next step size to use.

\[
\text{rk4qc}(y,n,x1,\text{step},\text{eps},\text{yscal},\text{derivs},t1,t2,t3,t4,t5,t6,t7)
\]

is the same as

\[
\text{rk4qc}(y,n,x1,\text{step},\text{eps},\text{yscal},\text{derivs})
\]

except that the user must provide the 7 scratch arrays t1-t7 of size n.

\[
\text{rk4a}(y,n,x1,x2,\text{eps},h,\text{ns},\text{derivs})
\]

is a driver program which uses rk4qc to integrate n ordinary differential equations starting at x1 to x2, keeping the local truncation error to within eps by changing the local step size.

The scaling vector is defined as

\[ \text{yscal}(i) = \text{abs}(y(i)) + \text{abs}(h\times dydx(i)) + \text{tiny} \]

where y(i) is the solution at location x, dydx is the ordinary differential equation's right hand side, h is the current step size and tiny is 10 times the smallest positive number representable.

The user must supply an estimate for a trial step size and the maximum number of calls to rk4qc to use. Argument x2 is the final point, eps is local truncation, ns is the maximum number of call to rk4qc to use.

++ Author: Yurij Baransky
++ Date Created: October 90
++ Date Last Updated: October 90
++ Description:
++ This package is a suite of functions for the numerical integration of an
++ ordinary differential equation of n variables:
++ \[ \frac{dy}{dx} = f(y,x) \] \[ y \] is an n-vector
++ All the routines are based on a 4-th order Runge-Kutta kernel.
++ These routines generally have as arguments:
++ \( n \), the number of dependent variables;
++ \( x_1 \), the initial point;
++ \( h \), the step size;
++ \( y \), a vector of initial conditions of length \( n \);
++ which upon exit contains the solution at \( x_1 + h \);
++ \( \text{derivs} \), a function which computes the right hand side of the
++ ordinary differential equation: \( \text{derivs}(dydx,y,x) \) computes
++ \( \text{derivs}(dydx) \), a vector which contains the derivative information.
++ In order of increasing complexity:
++ \[ \text{rk4}(y,n,x_1,h,\text{derivs}) \] advances the solution vector to
\( \text{rk4}(y, n, x_1, h, \text{derivs}) \) is the same as \( \text{rk4}(y, n, x_1, h, \text{derivs}, t_1, t_2, t_3, t_4) \) except that you must provide 4 scratch arrays \( t_1-t_4 \) of size \( n \).

Starting with \( y \) at \( x_1 \), \( \text{rk4f}(y, n, x_1, x_2, \text{ns}, \text{derivs}) \) uses \( \text{ns} \) fixed steps of a 4-th order Runge-Kutta integrator to advance the solution vector to \( x_2 \) and return \( y \). Argument \( x_2 \), is the final point, and \( \text{ns} \), the number of steps to take.

\( \text{rk4qc}(y, n, x_1, \text{step}, \text{eps}, \text{yscal}, \text{derivs}) \) takes a 5-th order Runge-Kutta step with monitoring of local truncation to ensure accuracy and adjust stepsize.

The function takes two half steps and one full step and scales the difference in solutions at the final point. If the error is within \( \text{eps} \), the step is taken and the result is returned. If the error is not within \( \text{eps} \), the stepsize if decreased and the procedure is tried again until the desired accuracy is reached. Upon input, an trial step size must be given and upon return, an estimate of the next step size to use is returned as well as the step size which produced the desired accuracy.

The scaled error is computed as

\[ \text{error} = \text{MAX}(\text{ABS}((y_{2\text{steps}}(i) - y_{1\text{step}}(i))/\text{yscal}(i))) \]

and this is compared against \( \text{eps} \). If this is greater than \( \text{eps} \), the step size is reduced accordingly to

\[ \text{hnew} = 0.9 \times \text{hdid} \times (\text{error}/\text{eps})^{-1/4} \]

If the error criterion is satisfied, then we check if the step size was too fine and return a more efficient one. If

\[ \text{error} > (\text{6.0E-04}) \] then the next step size should be

\[ \text{hnext} = 0.9 \times \text{hdid} \times (\text{error}/\text{eps})^{-1/5} \]

Otherwise \( \text{hnext} = 4.0 \times \text{hdid} \) is returned.

A more detailed discussion of this and related topics can be found in the book "Numerical Recipies" by W. Press, B. P. Flannery, S. A. Teukolsky, W. T. Vetterling published by Cambridge University Press.

Argument \( \text{step} \) is a record of 3 floating point numbers \( \text{try, did, next} \), \( \text{eps} \) is the required accuracy, \( \text{yscal} \) is the scaling vector for the difference in solutions. On input, \( \text{step.try} \) should be the guess at a step size to achieve the accuracy. On output, \( \text{step.did} \) contains the step size which achieved the accuracy and \( \text{step.next} \) is the next step size to use.

\( \text{rk4qc}(y, n, x_1, \text{step}, \text{eps}, \text{yscal}, \text{derivs}, t_1, t_2, t_3, t_4, t_5, t_6, t_7) \) is the same as \( \text{rk4qc}(y, n, x_1, \text{step}, \text{eps}, \text{yscal}, \text{derivs}) \) except that the user must provide the 7 scratch arrays \( \text{t1-t7} \) of size \( n \).
CHAPTER 15. CHAPTER N

++ \spad{rk4a(y,n,x1,x2,eps,h,ns,derivs)}
++ is a driver program which uses \spad{rk4qc} to integrate n ordinary
++ differential equations starting at x1 to x2, keeping the local
++ truncation error to within \spad{eps} by changing the local step size.
++ The scaling vector is defined as:

NumericalQuadrature examples

This suite of routines performs numerical quadrature using algorithms derived from the basic trapezoidal rule. Because the error term of this rule contains only even powers of the step size (for open and closed versions), fast convergence can be obtained if the integrand is sufficiently smooth.

Each routine returns a Record of type TrapAns, which contains

- value Float: estimate of the integral
- error Float: estimate of the error in the computation
- totalpts Integer: total number of function evaluations
- success Boolean: if the integral was computed within the user specified error criterion

To produce this estimate, each routine generates an internal sequence of sub-estimates, denoted by S(i), depending on the
routine, to which the various convergence criteria are applied. The user must supply a relative accuracy, \( \epsilon_r \), and an absolute accuracy, \( \epsilon_a \). Convergence is obtained when either

\[
\text{ABS}(S(i) - S(i-1)) < \epsilon_r \times \text{ABS}(S(i-1))
\]

or

\[
\text{ABS}(S(i) - S(i-1)) < \epsilon_a
\]

are true statements.

The routines come in three families and three flavors:

- closed: romberg, simpson, trapezoidal
- open: rombergo, simpsono, trapezoidalo
- adaptive closed: aromberg, asimpson, atrapezoidal

The \( S(i) \) for the trapezoidal family is the value of the integral using an equally spaced abscissa trapezoidal rule for that level of refinement.

The \( S(i) \) for the simpson family is the value of the integral using an equally spaced abscissa simpson rule for that level of refinement.

The \( S(i) \) for the romberg family is the estimate of the integral using an equally spaced abscissa romberg method. For the \( i \)-th level, this is an appropriate combination of all the previous trapezodial estimates so that the error term starts with the \( 2^{*(i+1)} \) power only.

The three families come in a closed version, where the formulas include the endpoints, an open version where the formulas do not include the endpoints and an adaptive version, where the user is required to input the number of subintervals over which the appropriate closed family integrator will apply with the usual convergence parameters for each subinterval. This is useful where a large number of points are needed only in a small fraction of the entire domain.

Each routine takes as arguments:

- \( f \) integrand
- \( a \) starting point
- \( b \) ending point
- \( \epsilon_r \) relative error
- \( \epsilon_a \) absolute error
- \( n_{\text{min}} \) refinement level when to start checking for convergence (> 1)
- \( n_{\text{max}} \) maximum level of refinement

The adaptive routines take as an additional parameter, \( n_{\text{int}} \), the number of independent intervals to apply a closed family integrator of the same name.

Note that closed family level \( i \) uses \( 1 + 2^{*i} \) points.
Open family level \( i \) uses \( 1 + 3^{*i} \) points.

- \( \text{eps}_r \) relative error
- \( \text{eps}_a \) absolute error
- \( n_{\min} \) refinement level when to start checking for convergence (> 1)
- \( n_{\max} \) maximum level of refinement

The adaptive routines take as an additional parameter, \( n_{\text{int}} \), the number of independent intervals to apply a closed family integrator of the same name.

Notes:

- Closed family level \( i \) uses \( \text{spad}(1 + 2^*i) \) points.
- Open family level \( i \) uses \( \text{spad}(1 + 3^*i) \) points.

NumericalQuadrature(): Exports == Implementation where
\textbf{Exports} with

- \texttt{aromberg} : \((F \to F,F,F,F,I,I,I) \to \text{TrapAns}\)
  + uses the adaptive romberg method to numerically integrate function
  + \texttt{\textbackslash spad}(fn) over the closed interval from \texttt{\textbackslash spad}(a) to \texttt{\textbackslash spad}(b),
  + with relative accuracy \texttt{\textbackslash spad}(\texttt{epsrel}) and absolute accuracy
  + \texttt{\textbackslash spad}(\texttt{epsabs}), with the refinement levels for convergence checking
  + vary from \texttt{\textbackslash spad}(\texttt{nmin}) to \texttt{\textbackslash spad}(\texttt{nmax}), and where \texttt{\textbackslash spad}(\texttt{nint})
  + is the number of independent intervals to apply the integrator.
  + The value returned is a record containing the value of the integral,
  + the estimate of the error in the computation, the total number of
  + function evaluations, and either a boolean value which is true if
  + the integral was computed within the user specified error criterion.
  + See \texttt{\textbackslash spadtype\{NumericalQuadrature\}} for details.

- \texttt{asimpson} : \((F \to F,F,F,F,I,I,I) \to \text{TrapAns}\)
  + uses the adaptive simpson method to numerically integrate function \texttt{\textbackslash spad}(fn)
  + over the closed interval from \texttt{\textbackslash spad}(a) to \texttt{\textbackslash spad}(b), with relative
  + accuracy \texttt{\textbackslash spad}(\texttt{epsrel}) and absolute accuracy \texttt{\textbackslash spad}(\texttt{epsabs}), with the
  + refinement levels for convergence checking vary from \texttt{\textbackslash spad}(\texttt{nmin})
  + to \texttt{\textbackslash spad}(\texttt{nmax}), and where \texttt{\textbackslash spad}(\texttt{nint}) is the number of independent
  + intervals to apply the integrator. The value returned is a record
  + containing the value of the integral, the estimate of the error in
  + the computation, the total number of function evaluations, and
  + either a boolean value which is true if the integral was computed

romberg : (F -> F,F,F,F,F,I,I) -> TrapAns
  ++ romberg(fn,a,b,epsrel,epsabs,nmin,nmax) uses the romberg
  ++ method to numerically integrate function \spad{fn} over the closed
  ++ interval \spad{a} to \spad{b}, with relative accuracy \spad{epsrel}
  ++ and absolute accuracy \spad{epsabs}, with the refinement levels
  ++ for convergence checking vary from \spad{nmin} to \spad{nmax}.
  ++ The value returned is a record containing the value
  ++ of the integral, the estimate of the error in the computation, the
  ++ total number of function evaluations, and either a boolean value
  ++ which is true if the integral was computed within the user specified
  ++ error criterion. See \spadtype{NumericalQuadrature} for details.
simpson : (F -> F,F,F,F,F,I,I) -> TrapAns
  ++ simpson(fn,a,b,epsrel,epsabs,nmin,nmax) uses the simpson
  ++ method to numerically integrate function \spad{fn} over the closed
  ++ interval \spad{a} to \spad{b}, with
  ++ relative accuracy \spad{epsrel} and absolute accuracy \spad{epsabs},
  ++ with the refinement levels for convergence checking vary from
  ++ \spad{nmin} to \spad{nmax}. The value returned
  ++ is a record containing the value of the integral, the estimate of
  ++ the error in the computation, the total number of function
  ++ evaluations, and either a boolean value which is true if
  ++ the integral was computed within the user specified error criterion.
  ++ See \spadtype{NumericalQuadrature} for details.
trapezoidal : (F -> F,F,F,F,F,I,I) -> TrapAns
  ++ trapezoidal(fn,a,b,epsrel,epsabs,nmin,nmax) uses the
  ++ trapezoidal method to numerically integrate function \spad{fn} over
  ++ the closed interval \spad{a} to \spad{b}, with
  ++ relative accuracy \spad{epsrel} and absolute accuracy \spad{epsabs},
  ++ with the refinement levels for convergence checking vary
  ++ from \spad{nmin} to \spad{nmax}. The value returned
  ++ is a record containing the value of the integral, the estimate of
  ++ the error in the computation, the total number of function
  ++ evaluations, and either a boolean value which is true if
  ++ the integral was computed within the user specified error criterion.
  ++ See \spadtype{NumericalQuadrature} for details.
rombergo : (F -> F,F,F,F,F,I,I) -> TrapAns
  ++ rombergo(fn,a,b,epsrel,epsabs,nmin,nmax) uses the romberg
  ++ method to numerically integrate function \spad{fn} over
  ++ the open interval from \spad{a} to \spad{b}, with
  ++ relative accuracy \spad{epsrel} and absolute accuracy \spad{epsabs},
  ++ with the refinement levels for convergence checking vary from
  ++ \spad{nmin} to \spad{nmax}. The value returned
  ++ is a record containing the value of the integral, the estimate of
  ++ the error in the computation, the total number of function
  ++ evaluations, and either a boolean value which is true if
  ++ the integral was computed within the user specified error criterion.
  ++ See \spadtype{NumericalQuadrature} for details.
simpsono : (F -> F,F,F,F,F,I,I) -> TrapAns
  ++ simpsono(fn,a,b,epsrel,epsabs,nmin,nmax) uses the
  ++ simpson method to numerically integrate function \spad{fn} over
  ++ the open interval from \spad{a} to \spad{b}, with
  ++ relative accuracy \spad{epsrel} and absolute accuracy \spad{epsabs},
  ++ with the refinement levels for convergence checking vary from
  ++ \spad{nmin} to \spad{nmax}. The value returned
  ++ is a record containing the value of the integral, the estimate of
  ++ the error in the computation, the total number of function
  ++ evaluations, and either a boolean value which is true if
  ++ the integral was computed within the user specified error criterion.
  ++ See \spadtype{NumericalQuadrature} for details.
++ the open interval from \spad{a} to \spad{b}, with
++ relative accuracy \spad{epsrel} and absolute accuracy \spad{epsabs},
++ with the refinement levels for convergence checking vary from

OneDimensionalArrayFunctions2 (ARRAY12)

Exports:
map reduce scan

— package ARRAY12 OneDimensionalArrayFunctions2 —

)abbrev package ARRAY12 OneDimensionalArrayFunctions2
++ Description:
++ This package provides tools for operating on one-dimensional arrays
++ with unary and binary functions involving different underlying types

OneDimensionalArrayFunctions2(A, B): Exports == Implementation where
A, B: Type

VA ==> OneDimensionalArray A
VB ==> OneDimensionalArray B
O2 ==> FiniteLinearAggregateFunctions2(A, VA, B, VB)

Exports ==> with
scan : ((A, B) -> B, VA, B) -> VB
++ scan(f,a,r) successively applies
++ \spad{reduce(f,x,r)} to more and more leading sub-arrays
++ x of one-dimensional array \spad{a}.
++ More precisely, if \spad{a} is \spad{[a1,a2,...]}, then
++ \spad{scan(f,a,r)} returns
++ \spad{[reduce(f,[a1],r),reduce(f,[a1,a2],r),...]}.
++
++X T1:=OneDimensionalArrayFunctions2(Integer,Integer)
++X adder(a:Integer,b:Integer):Integer == a+b
++X scan(adder,[i for i in 1..10],0)$T1

reduce : ((A, B) -> B, VA, B) -> B
++ reduce(f,a,r) applies function f to each
++ successive element of the
++ one-dimensional array \spad{a} and an accumulant initialized to r.
++ For example, \spad{reduce(_+$_Integer,[1,2,3],0)}
\( \text{spad}\{3+(2+(1+0))\} \). Note that third argument \( r \) may be regarded as the identity element for the function \( f \).

\[ X \ T1 := \text{OneDimensionalArrayFunctions2}(\text{Integer}, \text{Integer}) \]
\[ X \ \text{adder}(a: \text{Integer}, b: \text{Integer}): \text{Integer} = a + b \]
\[ X \ \text{reduce}(\text{adder}, [i \text{ for } i \text{ in } 1..10], 0) \]$T1

\[ \text{map} : (A \to B, VA) \to VB \]
\[ \text{map}(f, a) \text{ applies function } f \text{ to each member of one-dimensional array } \text{spad}\{a\} \text{ resulting in a new one-dimensional array over a possibly different underlying domain.} \]
\[ X \ T1 := \text{OneDimensionalArrayFunctions2}(\text{Integer}, \text{Integer}) \]
\[ X \ \text{map}(x+\to x+2, [i \text{ for } i \text{ in } 1..10])$T1

\[
\begin{align*}
\text{Implementation} & \Rightarrow \text{add} \\
\text{map}(f, v) & \Rightarrow \text{map}(f, v)$O2 \\
\text{scan}(f, v, b) & \Rightarrow \text{scan}(f, v, b)$O2 \\
\text{reduce}(f, v, b) & \Rightarrow \text{reduce}(f, v, b)$O2
\end{align*}

)abbrev package OUT OutputPackage
++ Author: Stephen M. Watt
++ Date Created: February 1986
++ Date Last Updated: October 27 1995 (MCD)
++ Description:
++ OutPackage allows pretty-printing from programs.

OutputPackage: with

    output: String -> Void
    ++ output(s) displays the string s on the ‘‘algebra output’’
    ++ stream, as defined by \spad{set output algebra}.

    output: OutputForm -> Void
    ++ output(x) displays the output form x on the
    ++ ‘‘algebra output’’ stream, as defined by
    ++ \spad{set output algebra}.

    output: (String, OutputForm) -> Void
    ++ output(s,x) displays the string s followed by the form x
    ++ on the ‘‘algebra output’’ stream, as defined by
    ++ \spad{set output algebra}.

    outputList: (List Any) -> Void
    ++ outputList(l) displays the concatenated components of the
    ++ list l on the ‘‘algebra output’’ stream, as defined by
    ++ \spad{set output algebra}; quotes are stripped
    ++ from strings.

    interpolateFormsForFact: (DIVISOR,List PolyRing) -> List(PolyRing)

    fullDesTree: () -> Void

    fullInfClsPt: () -> Void

    setCurve: PolyRing -> PolyRing

    projectivePoint: List K -> ProjPt

    pointDominateBy : Plc -> ProjPt
        ++ pointDominateBy(pl) returns the projective point dominated
        ++ by the place pl.

    placesAbove: ProjPt -> List Plc

    setSingularPoints: List ProjPt -> List ProjPt

    goppaCode: (DIVISOR,DIVISOR) -> Matrix K

    goppaCode: (DIVISOR,List(Plc)) -> Matrix K

    rationalPlaces: () -> List Plc
        ++ rationalPlaces returns all the rational places of the
        ++ curve defined by the polynomial given to the package.

    theCurve: () -> PolyRing
        ++ theCurve returns the specified polynomial for the package.

    genus: () -> NNI
        ++ genus returns the genus of the curve defined by the polynomial
        ++ given to the package.

    genusNeg: () -> Integer
desingTreeWoFullParam : () -> List DesTree
++ desingTreeWoFullParam returns the desingularisation trees at all
++ singular points of the curve defined by the polynomial given to
++ the package. The local parametrizations are not computed.

desingTree: () -> List DesTree
++ desingTree returns the desingularisation trees at all singular
++ points of the curve defined by the polynomial given to the package.

rationalPoints: () -> List(ProjPt)
singularPoints: () -> List(ProjPt)
++ rationalPoints() returns the singular points of the
++ curve defined by the polynomial given to the package.
++ If the singular points lie in an extension of the specified
++ ground field an error message is issued specifying the extension
++ degree needed to find all singular points.

parametrize: (PolyRing,Plc) -> PCS
++ parametrize(f,pl) returns a local parametrization of f at the place pl.

lBasis: (DIVISOR,NNI) -> List FRACPOLY

lBasis: DIVISOR -> Record(num:List PolyRing, den: PolyRing)
++ lBasis computes a basis associated to the specified divisor

findOrderOfDivisor: (DIVISOR,Integer,Integer) -> _.
Record(ord:Integer,num:PolyRing,den:PolyRing,upTo:Integer)

interpolateForms: (DIVISOR,NNI) -> List(PolyRing)
++ interpolateForms(d,n) returns a basis of the interpolate forms of
++ degree n of the divisor d.

eval: (PolyRing,Plc) -> K
++ eval(f,pl) evaluate f at the place pl.

eval: (PolyRing,PolyRing,Plc) -> K
++ eval(f,g,pl) evaluate the function f/g at the place pl.

eval: (FRACPOLY,Plc) -> K
++ eval(u,pl) evaluate the function u at the place pl.

evalIfCan: (PolyRing,Plc) -> Union(K,"failed")
++ evalIfCan(f,pl) evaluate f at the place pl
++ (returns "failed" if it is a pole).

evalIfCan: (PolyRing,PolyRing,Plc) -> Union(K,"failed")
++ evalIfCan(f,g,pl) evaluate the function f/g at the place pl
++ (returns "failed" if it is a pole).
evalIfCan: (FRACPOLY, Plc) -> Union(K, "failed")
++ evalIfCan(u, pl) evaluate the function u at the place pl
++ (returns "failed" if it is a pole).

intersectionDivisor: PolyRing -> DIVISOR
++ intersectionDivisor(pol) compute the intersection divisor (the
++ Cartier divisor) of the form pol with the curve. If some
++ intersection points lie in an extension of the ground field,
++ an error message is issued specifying the extension degree
++ needed to find all the intersection points.
++ (If pol is not homogeneous an error message is issued).

adjunctionDivisor: () -> DIVISOR
++ adjunctionDivisor computes the adjunction divisor of the plane
++ curve given by the polynomial set with the function setCurve.

if K has Finite then --should we say LocallyAlgebraicallyClosedField??

LPolynomial: () -> SparseUnivariatePolynomial Integer
++ Returns the L-Polynomial of the curve.

LPolynomial: PI -> SparseUnivariatePolynomial Integer
++ LPolynomial(d) returns the L-Polynomial of the curve in
++ constant field extension of degree d.

classNumber: () -> Integer
++ Returns the class number of the curve.

placesOfDegree: PI -> List Plc
++ placesOfDegree(d) returns all places of degree d of the curve.

numberOfPlacesOfDegree: PI -> Integer
++ returns the number of places of the given degree

numberRatPlacesExtDeg: PI -> Integer
++ numberRatPlacesExtDeg(n) returns the number of rational
++ places in the constant field extension of degree n

numberPlacesDegExtDeg: (PI, PI) -> Integer
++ numberRatPlacesExtDegExtDeg(d, n) returns the number of
++ places of degree d in the constant field extension of degree n

ZetaFunction: () -> UTSZ
++ Returns the Zeta function of the curve. Calculated by
++ using the L-Polynomial

ZetaFunction: PI -> UTSZ
++ Returns the Zeta function of the curve in constant field
++ extension. Calculated by using the L-Polynomial

lBasis: (DIVISOR,NNI) -> List FracPoly
   ++ lBasis computes a basis associated to the specified divisor.
findOrderOfDivisor: (DIVISOR,Integer,Integer) -> 
   Record(ord:Integer,num:PolyRing,den:PolyRing,upTo:Integer)
interpolateFormsForFact: (DIVISOR,List PolyRing) -> List(PolyRing2)
interpolateForms: (DIVISOR, NNI) -> List(PolyRing)
  ++ interpolateForms(d,n) returns a basis of the interpolate forms of
  ++ degree n of the divisor d.

eval: (PolyRing, Plc) -> K
  ++ eval(f,pl) evaluate f at the place pl.

eval: (PolyRing, PolyRing, Plc) -> K
  ++ eval(f,g,pl) evaluate the function f/g at the place pl.

eval: (FracPoly, Plc) -> K
  ++ eval(u,pl) evaluate the function u at the place pl.

evalIfCan: (PolyRing, Plc) -> Union(K, "failed")
  ++ evalIfCan(f,pl) evaluate f at the place pl
  ++ (returns "failed" if it is a pole).

evalIfCan: (PolyRing, PolyRing, Plc) -> Union(K, "failed")
  ++ evalIfCan(f,g,pl) evaluate the function f/g at the place pl
  ++ (returns "failed" if it is a pole).

evalIfCan: (FracPoly, Plc) -> Union(K, "failed")
  ++ evalIfCan(u,pl) evaluate the function u at the place pl
  ++ (returns "failed" if it is a pole).

intersectionDivisor: PolyRing -> DIVISOR
  ++ intersectionDivisor(pol) compute the intersection divisor of the
  ++ form pol with the curve.
  ++ (If pol is not homogeneous an error message is issued).

adjunctionDivisor: () -> DIVISOR
  ++ adjunctionDivisor computes the adjunction divisor of the plane
  ++ curve given by the polynomial defined by setCurve.

if DK has Finite then --should we say LocallyAlgebraicallyClosedField??

LPolynomial: () -> SparseUnivariatePolynomial Integer
  ++ Returns the L-Polynomial of the curve.

LPolynomial: PI -> SparseUnivariatePolynomial Integer
  ++ LPolynomial(d) returns the L-Polynomial of the curve in
  ++ constant field extension of degree d.

classNumber: () -> Integer
  ++ Returns the class number of the curve.

placesOfDegree: PI -> List Plc
  ++ placesOfDegree(d) returns all places of degree d of the
  ++ curve.
numberOfPlacesOfDegree: PI -> Integer
++ returns the number of places of the given degree

numberRatPlacesExtDeg: PI -> Integer
++ numberRatPlacesExtDeg(n) returns the number of rational
++ places in the constant field extension of degree n

numberPlacesDegExtDeg: (PI, PI) -> Integer
++ numberRatPlacesExtDegExtDeg(d, n) returns the number of
++ places of degree d in the constant field extension of
++ degree n

ZetaFunction: () -> UTSZ
++ Returns the Zeta function of the curve. Calculated by
++ using the L-Polynomial

ZetaFunction: PI -> UTSZ
++ Returns the Zeta function of the curve in constant field
++ extension. Calculated by using the L-Polynomial

PAdicWildFunctionFieldIntegralBasis examples
====================================================================

In this package K is a finite field, R is a ring of univariate polynomials over K, and F is a monogenic algebra over R.

We require that F is monogenic, i.e. that F = K[x,y]/(f(x,y)), because the integral basis algorithm used will factor the polynomial f(x,y). The package provides a function to compute the integral
closure of \( R \) in the quotient field of \( F \) as well as a function to compute a "local integral basis" at a specific prime.

This package completely solves a parametric linear system of equations by decomposing the set of all parametric values for which the linear system is consistent into a union of quasi-algebraic sets (which need not be irredundant, but most of the time is). Each quasi-algebraic set is described by a list of polynomials that vanish on the set, and a list of polynomials that vanish at no point of the set. For each quasi-algebraic set, the solution of the linear system is given, as a particular solution and a basis of the homogeneous system.

The parametric linear system should be given in matrix form, with a coefficient matrix and a right hand side vector. The entries of the coefficient matrix and right hand side vector should be polynomials in the parametric variables, over a Euclidean domain of characteristic zero.

If the system is homogeneous, the right hand side need not be given. The right hand side can also be replaced by an indeterminate vector, in which case, the conditions required for consistency will also be given.

The package has other facilities for saving results to external files, as well as solving the system for a specified minimum rank. Altogether there are 12 mode maps for psolve, as explained below.

-- updated with comments for MB, 02/16/94
-- also cleaned up some unnecessary arguments in regime routine
--
-- MB: In order to allow the rhs to be indeterminate, while working
-- mainly with the parametric variables on the lhs (less number of
-- variables), certain conversions of internal representation from
-- GR to Polynomial R and Fraction Polynomial R are done. At the time
-- of implementation, I thought that this may be more efficient. I
-- have not done any comparison since that requires rewriting the
-- package. My own application needs to call this package quite often,
-- and most computations involves only polynomials in the parametric
-- variables.

-- The 12 modes of psolve are probably not all necessary. Again, I
-- was thinking that if there are many regimes and many ranks, then
-- the output is quite big, and it may be nice to be able to save it
-- and read the results in later to continue computing rather than
-- recomputing. Because of the combinatorial nature of the algorithm
-- (computing all subdeterminants!), it does not take a very big matrix
-- to get into many regimes. But I now have second thoughts of this
design, since most of the time, the results are just intermediate,
passed to be further processed. On the other hand, there is probably
no penalty in leaving the options as is.

— package PLEQN ParametricLinearEquations —

)}

parametric linear system should be given in matrix form, with
+ a coefficient matrix and a right hand side vector. The entries
+ of the coefficient matrix and right hand side vector should be
+ polynomials in the parametric variables, over a Euclidean domain
+ of characteristic zero.

++ If the system is homogeneous, the right hand side need not be given.
++ The right hand side can also be replaced by an indeterminate vector,
++ in which case, the conditions required for consistency will also be
++ given.
++ The package has other facilities for saving results to external
++ files, as well as solving the system for a specified minimum rank.
++ Altogether there are 12 mode maps for psolve, as explained below.

ParametricLinearEquations(R,Var,Expon,GR):
  Declaration == Definition where

  R : Join(EuclideanDomain, CharacteristicZero)
  Var : Join(OrderedSet,ConvertibleTo (Symbol))
  Expon : OrderedAbelianMonoidSup
  GR : PolynomialCategory(R,Expon,Var)
  F == Fraction R

-- MB: The following macros are data structures to store mostly
-- intermediate results
-- Rec stores a subdeterminant with corresponding row and column indices
-- Fgb is a Groebner basis for the ideal generated by the subdeterminants
-- of a given rank.
-- Linsys specifies a linearly independent system of a given system
-- assuming a given rank, using given row and column indices
-- Linsoln stores the solution to the parametric linear system as a basis
-- and a particular solution (for a given regime)
-- Rec2 stores the rank, and a list of subdeterminants of that rank,
-- and a Groebner basis for the ideal they generate.
-- Rec3 stores a regime and the corresponding solution; the regime is
-- given by a list of equations (eqzro) and one inequation (neqzro)
-- describing the quasi-algebraic set which is the regime; the
-- additional consistency conditions due to the rhs is given by wcond.
-- Ranksolns stores a list of regimes and their solutions, and the number
-- of regimes all together.
-- Rec8 (temporary) stores a quasi-algebraic set with an indication
-- whether it is empty (sysok = false) or not (sysok = true).

-- I think psolve should be renamed parametricSolve, or even
-- parametricLinearSolve. On the other hand, may be just solve will do.
-- Please feel free to change it to conform with system conventions.
-- Most psolve routines return a list of regimes and solutions,
-- except those that output to file when the number of regimes is
-- returned instead.
-- This version has been tested on the pc version 1.608 March 13, 1992

++ wrregime(l,s) writes a list of regimes to a file named s
++ and returns the number of regimes written
rdregime : S -> L Rec3
++ rdregime(s) reads in a list from a file with name s
++ for internal use only --
++ these are exported so my other packages can use them
bsolve: (M GR, L GF, NNI, S, Inputmode) -> Ranksolns
++ bsolve(c, w, r, s, m) returns a list of regimes and
++ solutions of the system c z = w for ranks at least r;
++ depending on the mode m chosen, it writes the output to
++ a file given by the string s.
dmp2rfi: GR -> GF
++ dmp2rfi(p) converts p to target domain
dmp2rfi: M GR -> M GF
++ dmp2rfi(m) converts m to target domain
dmp2rfi: L GR -> L GF
++ dmp2rfi(l) converts l to target domain
se2rfi: L Symbol -> L GF
++ se2rfi(l) converts l to target domain
pr2dmp: PR -> GR
++ pr2dmp(p) converts p to target domain
hasoln: (Fgb, L GR) -> Rec8
++ hasoln(g, l) tests whether the quasi-algebraic set
++ defined by p = 0 for p in g and q ^= 0 for q in l
++ is empty or not and returns a simplified definition
++ of the quasi-algebraic set
-- this is now done in QALGSET package
ParCondList: (M GR,NNI) -> RankConds
  ++ ParCondList(c,r) computes a list of subdeterminants of each
  ++ rank >= r of the matrix c and returns
  ++ a groebner basis for the
  ++ ideal they generate
redpps: (Linsoln, Fgb) -> Linsoln
  ++ redpps(s,g) returns the simplified form of s after reducing
  ++ modulo a groebner basis g

-- LOCAL FUNCTIONS

B1solve: Linsys -> Linsoln
  ++ B1solve(s) solves the system (s.mat) z = s.vec
  ++ for the variables given by the column indices of s.cols
  ++ in terms of the other variables and the right hand side s.vec
  ++ by assuming that the rank is s.rank,
  ++ that the system is consistent, with the linearly
  ++ independent equations indexed by the given row indices s.rows;
  ++ the coefficients in s.mat involving parameters are treated as
  ++ polynomials. B1solve(s) returns a particular solution to the
  ++ system and a basis of the homogeneous system (s.mat) z = 0.
factorset: GR -> L GR
  ++ factorset(p) returns the set of irreducible factors of p.
maxrank: RankConds -> NNI
  ++ maxrank(r) returns the maximum rank in the list r of regimes
minrank: RankConds -> NNI
  ++ minrank(r) returns the minimum rank in the list r of regimes
minset: L L GR -> L L GR
  ++ minset(sl) returns the sublist of sl consisting of the minimal
  ++ lists (with respect to inclusion) in the list sl of lists
nextSublist: (I, I) -> L L I
  ++ nextSublist(n,k) returns a list of k-subsets of {1, ..., n}.
overset?: (L GR, L L GR) -> Boolean
  ++ overset?(s,sl) returns true if s properly a sublist of a member
  ++ of sl; otherwise it returns false
ParCond : (M GR,NNI) -> Eqns
  ++ ParCond(m,k) returns the list of all k by k subdeterminants in
  ++ the matrix m
redmat: (M GR, Fgb) -> M GR
  ++ redmat(m,g) returns a matrix whose entries are those of m
  ++ modulo the ideal generated by the groebner basis g
regime: (Rec,M GR,L GF,L L GR,NNI,NNI,Inputmode) -> Rec3
  ++ regime(y,c, w, p, r, rm, m) returns a regime,
  ++ a list of polynomials specifying the consistency conditions,
  ++ a particular solution and basis representing the general
  ++ solution of the parametric linear system c z = w
  ++ on that regime. The regime returned depends on
++ the subdeterminant y.det and the row and column indices.
++ The solutions are simplified using the assumption that
++ the system has rank r and maximum rank rm. The list p
++ represents a list of list of factors of polynomials in
++ a groebner basis of the ideal generated by higher order
++ subdeterminants, and ius used for the simplification.
++ The mode m
++ distinguishes the cases when the system is homogeneous,
++ or the right hand side is arbitrary, or when there is no
++ new right hand side variables.

sqfree: GR -> GR
++ sqfree(p) returns the product of square free factors of p

inconsistent?: L GR -> Boolean
++ inconsistent?(pl) returns true if the system of equations
++ p = 0 for p in pl is inconsistent. It is assumed
++ that pl is a groebner basis.
-- this is needed because of change to
-- EuclideanGroebnerBasisPackage

inconsistent?: L PR -> Boolean
++ inconsistent?(pl) returns true if the system of equations
++ p = 0 for p in pl is inconsistent. It is assumed
++ that pl is a groebner basis.
-- this is needed because of change to
-- EuclideanGroebnerBasisPackage

**DESCRIPTION:**

The following is part of the PAFF package

**PARAMP**

**DIRPCAT**

**PFECAT**
parametrize: (PolyRing, Plc) -> PCS
++ parametrize(f, pl) returns the local parametrization of the
++ polynomial function f at the place pl. Note that local
++ parametrization of the place must have first been computed and set.
++ For simple point on a curve, this done with \spad{pointToPlace}.
++ The local parametrization places corresponding to a leaf in a
++ desingularization tree are computed at the moment of
++ their "creation". (See package \spad{DesingTreePackage}).

parametrize: (PolyRing, PolyRing, Plc) -> PCS
++ parametrize(f, g, pl) returns the local parametrization of the
++ rational function f/g at the place pl. Note that local
++ parametrization of the place must have first been computed and set.
++ For simple point on a curve, this done with \spad{pointToPlace}.
++ The local parametrization places corresponding to a leaf in a
++ desingularization tree are computed at the moment of
++ their "creation". (See package \spad{DesingTreePackage}).

parametrize: (PolyRing, Plc, Integer) -> PCS
++ parametrize(f, pl, n) returns t^n * parametrize(f, p).

)lisp (bye)
a := x + 1/(y+1)

it will end up with the result in Fraction Polynomial Integer.

\[
\frac{x y + x + 1}{y + 1}
\]

We might want it in a partial fraction form. This can be done with:

```
partialFraction(a, y)$PFRPAC(INT)
```

```
1
x + ------
y + 1
```

We can do the same thing with a different variable:

b := y + 1/(x+1)

\[
\frac{(x + 1)y + 1}{x + 1}
\]

```
partialFraction(b, x)$PFRPAC(INT)
```

```
1
y + ------
x + 1
```

++ Date Last Updated: 3 April 1991
++ Description:
++ PartitionsAndPermutations contains functions for generating streams of
++ integer partitions, and streams of sequences of integers
++ composed from a multi-set.

PartitionsAndPermutations:Exports == Implementation where
   I  == Integer
   L  == List
   ST == Stream
   ST1 == StreamFunctions1
   ST2 == StreamFunctions2
   ST3 == StreamFunctions3

Exports ==> with

   partitions: (I,I,I) -> ST L I
      "\textsf{partitions}(p,l,n)" is the stream of partitions
      of \emph{n} whose number of parts is no greater than \emph{p}
      and whose largest part is no greater than \emph{l}.
   partitions: I    -> ST L I
      "\textsf{partitions}(n)" is the stream of all partitions of \emph{n}.
   partitions: (I,I) -> ST L I
      "\textsf{partitions}(p,l)" is the stream of all
      partitions whose number of
      parts and largest part are no greater than \emph{p} and \emph{l}. 
conjugate: L I -> L I
   \spad{conjugate(pt)} is the conjugate of the partition pt.
conjugates: ST L I -> ST L I
   \spad{conjugates(lp)} is the stream of conjugates of a stream
   of partitions lp.
shuffle: (L I,L I) -> ST L I
   \spad{shuffle(l1,l2)} forms the stream of all shuffles of l1
   and l2, i.e. all sequences that can be formed from
   merging l1 and l2.
shufflein: (L I,ST L I) -> ST L I
   \spad{shufflein(l,st)} maps shuffle(l,u) on to all
   members u of st, concatenating the results.
sequences: (L I,L I) -> ST L I
   \spad{sequences(l1,l2)} is the stream of all sequences that
   can be composed from the multiset defined from
   two lists of integers l1 and l2.
   For example, the pair \spad{([1,2,4],[2,3,5])} represents
   multi-set with 1 \spad{2}'s, 2 \spad{3}'s, and 4 \spad{5}'s.
sequences: L I -> ST L I
   \spad{sequences(l1)} is the set of
   all sequences formed from
   \spad{l1} 0's, \spad{1} 1's, \spad{2} 2's,..., \spad{n} n's.
permutations: I -> ST L I
   \spad{permutations(n)} is the stream of permutations
   formed from \spad{1,2,3,...,n}.

Permanent examples
====================================================================

The package Permanent provides the function permanent for square matrices. The permanent of a square matrix can be computed in the same way as the determinant by expansion of minors except that for the permanent the sign for each element is 1, rather than being 1 if the row plus column indices is positive and -1 otherwise. This function is much more difficult to compute efficiently than the determinant. An example of the use of permanent is the calculation of the n-th derangement number, defined to be the number of different possibilities for n couples to dance but never with their own spouse.

Consider an n by n matrix with entries 0 on the diagonal and 1 elsewhere. Think of the rows as one-half of each couple (for example, the males) and the columns the other half. The permanent of such a matrix gives the desired derangement number.

```
kn n ==
  r : MATRIX INT := new(n,n,1)
  for i in 1..n repeat
    r.i.i := 0
  r
```
Here are some derangement numbers, which you see grow quite fast.

\[
\text{permanent}(\text{kn}(5) :: \text{SQMATRIX}(5, \text{INT}))
\]

\[
[\text{permanent}(\text{kn}(n) :: \text{SQMATRIX}(n, \text{INT})) \text{ for } n \text{ in 1..13}]
\]

)abbrev package PERMAN Permanent
++ Authors: Johannes Grabmeier, Oswald Gschnitzer
++ Date Created: 7 August 1989
++ Date Last Updated: 23 August 1990
++ References:
++ Description:
  ++ Permanent implements the functions permanent, the permanent for square matrices.
Permanent(n : PositiveInteger, R : Ring with commutative("*")):
public == private where
  I ==> Integer
  L ==> List
  V ==> Vector
  SM ==> SquareMatrix(n,R)
  VECTPKG1 ==> VectorPackage1(I)
  NNI ==> NonNegativeInteger
  PI ==> PositiveInteger
  GRAY ==> GrayCode

public ==> with

  permanent: SM -> R
  ++ permanent(x) computes the permanent of a square matrix x.
  ++ The permanent is equivalent to
  ++ the \spadfun{determinant} except that coefficients have
  ++ no change of sign. This function
  ++ is much more difficult to compute than the
  ++ determinant. The formula used is by H.J. Ryser,
  ++ improved by [Nijenhuis and Wilf, Ch. 19].
  ++ Note that permanent(x) choose one of three algorithms, depending
  ++ on the underlying ring R and on n, the number of rows (and
  ++ columns) of x:
  ++ if 2 has an inverse in R we can use the algorithm of
  ++ [Nijenhuis and Wilf, ch.19,p.158]; if 2 has no inverse,
  ++ some modifications are necessary:
  ++ different from 2 (the algorithm works if and only 2 is not a
  ++ zero-divisor of R and characteristic(R) \not= 2,
  ++ but how to check that for any given R?),
  ++ the local function permanent2 is called;
  ++ else, the local function permanent3 is called
  ++ (works for all commutative rings R).

private ==> add

--R
PermutationGroupExamples provides permutation groups for some classes of groups: symmetric, alternating, dihedral, cyclic, direct products of cyclic, which are in fact the finite abelian groups of symmetric groups called Young subgroups. Furthermore, Rubik's group as permutation group of 48 integers and a list of sporadic simple groups derived from the atlas of finite groups.

symmetricGroup: PI -> PERMGRP I
  ++ symmetricGroup(n) constructs the symmetric group Sn
  ++ acting on the integers 1,...,n, generators are the
  ++ n-cycle (1,...,n) and the 2-cycle (1,2).
symmetricGroup: L I -> PERMGRP I
  ++ symmetricGroup(li) constructs the symmetric group acting on
  ++ the integers in the list li, generators are the
  ++ cycle given by li and the 2-cycle (li.1,li.2).
  ++ Note that duplicates in the list will be removed.
alternatingGroup: PI -> PERMGRP I
  ++ alternatingGroup(n) constructs the alternating group An
  ++ acting on the integers 1,...,n, generators are in general the
  ++ n-2-cycle (3,...,n) and the 3-cycle (1,2,3)
  ++ if n is odd and the product of the 2-cycle (1,2) with
  ++ n-2-cycle (3,...,n) and the 3-cycle (1,2,3)
  ++ if n is even.
alternatingGroup: L I -> PERMGRP I
  ++ alternatingGroup(li) constructs the alternating group acting
  ++ on the integers in the list li, generators are in general the
  ++ n-2-cycle (li.3,...,li.n) and the 3-cycle
  ++ (li.1,li.2,li.3), if n is odd and
  ++ product of the 2-cycle (li.1,li.2) with
  ++ n-2-cycle (li.3,...,li.n) and the 3-cycle
  ++ (li.1,li.2,li.3), if n is even.
  ++ Note that duplicates in the list will be removed.
abelianGroup: L PI -> PERMGRP I
  ++ abelianGroup([n1,...,nk]) constructs the abelian group that
  ++ is the direct product of cyclic groups with order ni.
cyclicGroup: PI -> PERMGRP I
  ++ cyclicGroup(n) constructs the cyclic group of order n acting
  ++ on the integers 1,...,n.
cyclicGroup: L I -> PERMGRP I
  ++ cyclicGroup([i1,...,ik]) constructs the cyclic group of
  ++ order k acting on the integers i1,...,ik.
  ++ Note that duplicates in the list will be removed.
dihedralGroup: PI -> PERMGRP I
  ++ dihedralGroup(n) constructs the dihedral group of order 2n
  ++ acting on integers 1,...,N.
dihedralGroup: L I -> PERMGRP I
  ++ dihedralGroup([i1,...,ik]) constructs the dihedral group of
  ++ order 2k acting on the integers out of i1,...,ik.
  ++ Note that duplicates in the list will be removed.
mathieu11: L I -> PERMGRP I
  ++ mathieu11(li) constructs the mathieu group acting on the 11
  ++ integers given in the list li.
  ++ Note that duplicates in the list will be removed.
  ++ error, if li has less or more than 11 different entries.
mathieu11: () -> PERMGRP I
++ mathieu11 constructs the mathieu group acting on the
++ integers 1,...,11.
mathieu12: L I -> PERMGRP I
++ mathieu12(li) constructs the mathieu group acting on the 12
++ integers given in the list li.
++ Note that duplicates in the list will be removed
++ Error: if li has less or more than 12 different entries.
mathieu12: () -> PERMGRP I
++ mathieu12 constructs the mathieu group acting on the
++ integers 1,...,12.
mathieu22: L I -> PERMGRP I
++ mathieu22(li) constructs the mathieu group acting on the 22
++ integers given in the list li.
++ Note that duplicates in the list will be removed.
++ Error: if li has less or more than 22 different entries.
mathieu22: () -> PERMGRP I
++ mathieu22 constructs the mathieu group acting on the
++ integers 1,...,22.
mathieu23: L I -> PERMGRP I
++ mathieu23(li) constructs the mathieu group acting on the 23
++ integers given in the list li.
++ Note that duplicates in the list will be removed.
++ Error: if li has less or more than 23 different entries.
mathieu23: () -> PERMGRP I
++ mathieu23 constructs the mathieu group acting on the
++ integers 1,...,23.
mathieu24: L I -> PERMGRP I
++ mathieu24(li) constructs the mathieu group acting on the 24
++ integers given in the list li.
++ Note that duplicates in the list will be removed.
++ Error: if li has less or more than 24 different entries.
mathieu24: () -> PERMGRP I
++ mathieu24 constructs the mathieu group acting on the
++ integers 1,...,24.
janko2: L I -> PERMGRP I
++ janko2(li) constructs the janko group acting on the 100
++ integers given in the list li.
++ Note that duplicates in the list will be removed.
++ Error: if li has less or more than 100 different entries.
janko2: () -> PERMGRP I
++ janko2 constructs the janko group acting on the
++ integers 1,...,100.
rubiksGroup: () -> PERMGRP I
++ rubiksGroup constructs the permutation group representing
++ Rubic’s Cube acting on integers 10*i+j for
++ 1 <= i <= 6, 1 <= j <= 8.
++ The faces of Rubik’s Cube are labelled in the obvious way
++ Front, Right, Up, Down, Left, Back and numbered from 1 to 6
++ in this given ordering, the pieces on each face
++ (except the unmoveable center piece) are clockwise numbered
**PACKAGE PGE PERMUTATIONGROUPEXAMPLES**

++ from 1 to 8 starting with the piece in the upper left corner. The moves of the cube are represented as permutations on these pieces, represented as a two digit integer \(ij\) where \(i\) is the number of the face (1 to 6) and \(j\) is the number of the piece on this face.
++ The remaining ambiguities are resolved by looking at the 6 generators, which represent a 90 degree turns of the faces, or from the following pictorial description.
++ Permutation group representing Rubik’s Cube acting on integers \(10i+j\) for \(1 \leq i \leq 6, 1 \leq j \leq 8\).
++
++ \begin{verbatim}
++ Rubik’s Cube: +-----+ +-- B where: marks Side # :
++ / U /|/
++ / / | F(ront) <-> 1
++ L --> +-----+ R| R(ight) <-> 2
++ | | + U(p) <-> 3
++ | F | / D(own) <-> 4
++ | |/ L(eft) <-> 5
++ +-----+ B(ack) <-> 6
++ ^
++ |
++ D
++
++ The Cube’s surface:
++ +---+ The pieces on each side
++ |567| (except the unmoveable center
++ |4U8| piece) are clockwise numbered
++ |321| from 1 to 8 starting with the
++ +---+ piece in the upper left
++ +---------+ corner (see figure on the
++ [781|123|345] left). The moves of the cube
++ [6L2|8F4|2R6] are represented as
++ [543|765|187] permutations on these pieces.
++ +----------+ Each of the pieces is
++ |123| represented as a two digit
++ |8D4| integer \(ij\) where \(i\) is the
++ |765| \# of the side ( 1 to 6 for
++ +---+ F to B (see table above ))
++ |567| and \(j\) is the \# of the piece.
++ |4B8|
++ |321|
++ +---+
++ \end{verbatim}

++ \begin{verbatim}
++ \end{verbatim}
++ youngGroup: L I -> PERMGRP I
++ youngGroup([n1,...,nk]) constructs the direct product of the symmetric groups \(S_{n1},...,S_{nk}\).
++ youngGroup: Partition -> PERMGRP I
++ youngGroup(lambda) constructs the direct product of the symmetric groups given by the parts of the partition lambda.

++ Description:
++ This package has no description

PointPackage(R:Ring):Exports == Implementation where

POINT ==> Point(R)
I ==> Integer
PI ==> PositiveInteger
NNI ==> NonNegativeInteger
L ==> List
B ==> Boolean

Exports == with
xCoord : POINT -> R 
  ++ xCoord(pt) returns the first element of the point, pt,
  ++ although no assumptions are made as to the coordinate
  ++ system being used. This function is defined for the
  ++ convenience of the user dealing with a Cartesian
  ++ coordinate system.
yCoord : POINT -> R
  ++ yCoord(pt) returns the second element of the point, pt,
  ++ although no assumptions are made as to the coordinate
  ++ system being used. This function is defined for the
  ++ convenience of the user dealing with a Cartesian
  ++ coordinate system.
zCoord : POINT -> R
  ++ zCoord(pt) returns the third element of the point, pt,
  ++ although no assumptions are made as to the coordinate
  ++ system being used. This function is defined for the
  ++ convenience of the user dealing with a Cartesian
  ++ or a cylindrical coordinate system.
rCoord : POINT -> R
  ++ rCoord(pt) returns the first element of the point, pt,
  ++ although no assumptions are made as to the coordinate
  ++ system being used. This function is defined for the
  ++ convenience of the user dealing with a spherical
  ++ or a cylindrical coordinate system.
thetaCoord : POINT -> R
  ++ thetaCoord(pt) returns the second element of the point, pt,
  ++ although no assumptions are made as to the coordinate
  ++ system being used. This function is defined for the
  ++ convenience of the user dealing with a spherical
  ++ or a cylindrical coordinate system.
phiCoord : POINT -> R
  ++ phiCoord(pt) returns the third element of the point, pt,
  ++ although no assumptions are made as to the coordinate
  ++ system being used. This function is defined for the
  ++ convenience of the user dealing with a spherical
  ++ coordinate system.

color : POINT -> R
  ++ color(pt) returns the fourth element of the point, pt,
  ++ although no assumptions are made with regards as to
  ++ how the components of higher dimensional points are
  ++ interpreted. This function is defined for the
  ++ convenience of the user using specifically, color
  ++ to express a fourth dimension.

hue : POINT -> R
  ++ hue(pt) returns the third element of the two dimensional point, pt,
  ++ although no assumptions are made with regards as to how the
  ++ components of higher dimensional points are interpreted. This
  ++ function is defined for the convenience of the user using
  ++ specifically, hue to express a third dimension.

shade : POINT -> R
  ++ shade(pt) returns the fourth element of the two dimensional
  ++ point, pt, although no assumptions are made with regards as to
  ++ how the components of higher dimensional points are interpreted.
  ++ This function is defined for the convenience of the user using
  ++ specifically, shade to express a fourth dimension.

====================================================================
PolyGroebner examples
====================================================================

This package is an interface package to the groebner basis package which allows you to compute groebner bases for polynomials in either lexicographic ordering or total degree ordering refined by reverse lex. The input is the ordinary polynomial type which is internally converted to a type with the required ordering. The resulting groebner basis is converted back to ordinary polynomials. The ordering among the variables is controlled by an explicit list of variables which is passed as a second argument. The coefficient
domain is allowed to be any gcd domain, but the groebner basis is computed as if the polynomials were over a field.

++ Description:
++ PolynomialFactorizationByRecursionUnivariate
++ R is a \spadfun{PolynomialFactorizationExplicit} domain,
++ S is univariate polynomials over R
++ We are interested in handling SparseUnivariatePolynomials over
++ S, is a variable we shall call \( z \)

PolynomialFactorizationByRecursionUnivariate(R, S): public == private where
R:PolynomialFactorizationExplicit
S:UnivariatePolynomialCategory(R)
PI ==> PositiveInteger
SupR ==> SparseUnivariatePolynomial R
SupSupR ==> SparseUnivariatePolynomial SupR
SupS ==> SparseUnivariatePolynomial S
SupSupS ==> SparseUnivariatePolynomial SupS
LPEBFS ==> LinearPolynomialEquationByFractions(S)

public == with
solveLinearPolynomialEquationByRecursion: (List SupS, SupS) ->
Union(List SupS,"failed")
++ \spad{solveLinearPolynomialEquationByRecursion([p1,...,pn],p)}
++ returns the list of polynomials \spad{[q1,...,qn]}
++ such that \spad{sum q_i/p_i = p / prod p_i}, a
++ recursion step for solveLinearPolynomialEquation
++ as defined in \spadfun{PolynomialFactorizationExplicit} category
++ (see \spadfun{solveLinearPolynomialEquation}).
++ If no such list of qi exists, then "failed" is returned.

factorByRecursion: SupS -> Factored SupS
++ factorByRecursion(p) factors polynomial p. This function
++ performs the recursion step for factorPolynomial,
++ as defined in \spadfun{PolynomialFactorizationExplicit} category
++ (see \spadfun{factorPolynomial}).
factorSquareFreeByRecursion: SupS -> Factored SupS
++ factorSquareFreeByRecursion(p) returns the square free
++ factorization of p. This function performs
++ the recursion step for factorSquareFreePolynomial,
++ as defined in \spadfun{PolynomialFactorizationExplicit} category
++ (see \spadfun{factorSquareFreePolynomial}).
randomR: -> R -- has to be global, since has alternative definitions
++ randomR() produces a random element of R
factorSFBRlcUnit: (SupS) -> Factored SupS
++ factorSFBRlcUnit(p) returns the square free factorization of
++ polynomial p
++ (see \spadfun{factorSquareFreeByRecursion}{PolynomialFactorizationByRecursionUnivariate})
++ in the case where the leading coefficient of p
++ is a unit.

=====================================================================
PolynomialGcdPackage examples
=====================================================================

This package computes multivariate polynomial gcd's using a hensel
lifting strategy. The contraint on the coefficient domain is imposed
by the lifting strategy. It is assumed that the coefficient domain has
the property that almost all specializations preserve the degree of
the gcd.

The simple Euclidean division algorithm,
given $a \neq 0$, $b \neq 0$ where $a$ and $b$ are two polynomials in the variable $x$, then

output $q$, the quotient and $r$, the remainder

begin

Let

$q = 0$
$r = a$
$d = \text{degree}(b)$
$c = \text{leadingCoefficient}(b)$

while $\text{degree}(r) \geq d$ do

$e = \text{degree}(r) - d$
$s = \frac{\text{leadingCoefficient}(r)}{e} x^{e}$
$q = q + s$
$r = r - sb$

endwhile

return $(q, r)$

end

For example, given

\[
p_1 := (x+1) \cdot (x+6) \\
p_2 := (x+1) \cdot (x-6)
\]
\[
gcd(p_1, p_2) \rightarrow x+1

In Gathen [Gath99] we find a discussion of applying the Euclidean algorithm to elements of a field. In a field every nonzero rational number is a unit. If we want to define a single element such that
\[\gcd(f, g) \in \mathbb{Q}[x] \]
we choose a monic polynomial, that is, the element with a leading coefficient of 1. So
\[abs(a/\text{leadingCoefficient}(a)) \]
defines a normal form of \(a\).

Gathen also notes that for polynomials we should modify the Euclidean algorithm so all remainders are normalized. Without this constraint the remainders will have huge numerators and denominators.

Hensel's lifting lemma states that if a polynomial equation has a simple root modulo a prime number \( p \), then this root corresponds to a unique root of the same equation modulo any higher power of \( p \), which can be found by iteratively “lifting” the solution modulo successive powers of \( p \).

See Volume 10.1 for more details.

++ over the integers.

PolynomialNumberTheoryFunctions(): Exports == Implementation where
I ==> Integer
RN ==> Fraction I
SUP ==> SparseUnivariatePolynomial
NNI ==> NonNegativeInteger
Exports == with bernoulli : I -> SUP RN
  ++ bernoulli(n) returns the nth Bernoulli polynomial \( B[n](x) \).
  ++ Bernoulli polynomials denoted \( B(n,x) \) computed by solving the
  ++ differential equation \( \text{differentiate}(B(n,x),x) = n B(n-1,x) \) where
  ++ \( B(0,x) = 1 \) and initial condition comes from \( B(n) = B(n,0) \).
chebyshevT: I -> SUP I
  ++ chebyshevT(n) returns the nth Chebyshev polynomial \( T[n](x) \).
  ++ Note that Chebyshev polynomials of the first kind,
  ++ denoted \( T(n,x) \),
  ++ computed from the two term recurrence. The generating function
  ++ \( \frac{(1-t*x)}{(1-2*t*x+t**2)} = \sum T[n](x)*t**n, n=0..infinity) \).
chebyshevU: I -> SUP I
  ++ chebyshevU(n) returns the nth Chebyshev polynomial \( U[n](x) \).
  ++ Note that Chebyshev polynomials of the second kind,
  ++ denoted \( U(n,x) \),
  ++ computed from the two term recurrence. The generating function
  ++ \( \frac{1}{(1-2*t*x+t**2)} = \sum T[n](x)*t**n, n=0..infinity) \).
cyclotomic: I -> SUP I
  ++ cyclotomic(n) returns the nth cyclotomic polynomial \( \phi[n](x) \).
  ++ Note that \( \phi[n](x) \) is the factor of \( x**n - 1 \) whose roots
  ++ are the primitive nth roots of unity.
euler : I -> SUP RN
  ++ euler(n) returns the nth Euler polynomial \( E[n](x) \).
  ++ Note that Euler polynomials denoted \( E(n,x) \) computed by solving
  ++ the differential equation
  ++ \( \text{differentiate}(E(n,x),x) = n E(n-1,x) \) where
  ++ \( E(0,x) = 1 \) and initial condition comes
  ++ from \( E(n) = 2**n E(n,1/2) \).
fixedDivisor: SUP I -> I
  ++ fixedDivisor(a) for \( a(x) \) in \( Z[x] \) is the largest integer
  ++ \( f \) such that \( f \) divides \( a(x=k) \) for all integers \( k \).
  ++ Note that fixed divisor of \( a \) is
  ++ \( \text{gcd}([a(x=k) \text{ for } k \text{ in } 0..\text{degree}(a)]) \).
hermite : I -> SUP I
  ++ hermite(n) returns the nth Hermite polynomial \( H[n](x) \).
  ++ Note that Hermite polynomials, denoted \( H[n](x) \), are computed from
  ++ the two term recurrence. The generating function is:
  ++ \( \exp(2*t*x-t**2) = \sum H[n](x)*t**n/n!, n=0..infinity) \).
laguerre : I -> SUP I
  ++ laguerre(n) returns the nth Laguerre polynomial \( L[n](x) \).
  ++ Note that Laguerre polynomials, denoted \( L[n](x) \), are computed
  ++ from the two term recurrence. The generating function is:
  ++ \( \exp(x*t/(t-1))/(1-t) = \sum L[n](x)*t**n/n!, n=0..infinity) \).
legendre : I -> SUP RN
  ++ legendre(n) returns the nth Legendre polynomial \( P[n](x) \).
  ++ Note that Legendre polynomials, denoted \( P[n](x) \), are computed
  ++ from the two term recurrence. The generating function is:
  ++ \( 1/sqrt(1-2*t*x+t**2) = \sum P[n](x)*t**n, n=0..infinity) \).

Exports == with

removeRedundantFactors: LP -> LP
++ \texttt{removeRedundantFactors(lp)} returns \texttt{lq} such that if
++ \texttt{lp = \{p1,...,pn\}} and \texttt{lq = \{q1,...,qm\}}
++ then the product \texttt{p1*p2*...*pn} vanishes iff the product \texttt{q1*q2*...*qm} vanishes,
++ and the product of degrees of the \texttt{qi} is not greater than
++ the one of the \texttt{pj}, and no polynomial in \texttt{lq}
++ divides another polynomial in \texttt{lq}. In particular,
++ polynomials lying in the base ring \texttt{R} are removed.
++ Moreover, \texttt{lq} is sorted \texttt{w.r.t. infRittWu?}.
++ Furthermore, if \texttt{R} is gcd-domain, the polynomials in \texttt{lq} are
++ pairwise without common non trivial factor.
removeRedundantFactors: (P,P) -> LP
++ \texttt{removeRedundantFactors(p,q)} returns the same as
++ \texttt{removeRedundantFactors(\{p,q\})}

removeSquaresIfCan : LP -> LP
++ \texttt{removeSquaresIfCan(lp)} returns
++ \texttt{removeDuplicates [squareFreePart(p)$P for p in lp\}}
++ if \texttt{R} is gcd-domain else returns \texttt{lp}.

unprotectedRemoveRedundantFactors: (P,P) -> LP
++ \texttt{unprotectedRemoveRedundantFactors(p,q)} returns the same as
++ \texttt{removeRedundantFactors(p,q)} but does assume that neither
++ \texttt{p} nor \texttt{q} lie in the base ring \texttt{R} and assumes that
++ \texttt{infRittWu?(p,q)} holds. Moreover, if \texttt{R} is gcd-domain,
++ then \texttt{p} and \texttt{q} are assumed to be square free.

removeRedundantFactors: (LP,P) -> LP
++ \texttt{removeRedundantFactors(lp,q)} returns the same as
++ \texttt{removeReduced(cons(q,lp))} assuming
++ that \texttt{lp} returns \texttt{lp} up to replacing some polynomial \texttt{pj} in \texttt{lp}
++ by some some polynomial \texttt{qj} associated to \texttt{pj}.
removeRedundantFactors : (LP,LP) -> LP
++ \axiom{removeRedundantFactors(lp,lq)} returns the same as
++ \axiom{removeRedundantFactors(concat(lp,lq))} assuming
++ that \axiom{removeRedundantFactors(lp)} returns \axiom{lp}
++ up to replacing some polynomial \axiom{pj} in \axiom{lp}
++ by some polynomial \axiom{qj} associated to \axiom{pj}.
removeRedundantFactors : (LP,LP,(LP -> LP)) -> LP
++ \axiom{removeRedundantFactors(lp,lq,remOp)} returns the same as
++ \axiom{concat(remOp(removeRoughlyRedundantFactorsInPols(lp,lq)),lq)}
++ assuming that \axiom{remOp(lp)} returns \axiom{lp} up to similarity.
certainlySubVariety? : (LP,LP) -> B
++ \axiom{certainlySubVariety?(newlp,lp)} returns true iff for every \axiom{p}
++ in \axiom{lp} the remainder of \axiom{p} by \axiom{newlp} using the division algorithm
++ of Groebner techniques is zero.
possiblyNewVariety? : (LP, List LP) -> B
++ \axiom{possiblyNewVariety?(newlp,llp)} returns true iff for every \axiom{lp}
++ in \axiom{llp} certainlySubVariety?(newlp,lp) does not hold.
probablyZeroDim?: LP -> B
++ \axiom{probablyZeroDim?(lp)} returns true iff the number of polynomials
++ in \axiom{lp} is not smaller than the number of variables occurring
++ in these polynomials.
selectPolynomials : ((P -> B),LP) -> Record(goodPols:LP,badPols:LP)
++ \axiom{selectPolynomials(pred?,ps)} returns \axiom{gps,bps} where
++ \axiom{gps} is a list of the polynomial \axiom{p} in \axiom{ps}
++ such that \axiom{pred?(p)} holds and \axiom{bps} are the other ones.
selectOrPolynomials : (List (P -> B),LP) -> Record(goodPols:LP,badPols:LP)
++ \axiom{selectOrPolynomials(lpred?,ps)} returns \axiom{gps,bps} where
++ \axiom{gps} is a list of the polynomial \axiom{p} in \axiom{ps}
++ such that \axiom{pred?(p)} holds for some \axiom{pred?} in \axiom{lpred?}
++ and \axiom{bps} are the other ones.
selectAndPolynomials : (List (P -> B),LP) -> Record(goodPols:LP,badPols:LP)
++ \axiom{selectAndPolynomials(lpred?,ps)} returns \axiom{gps,bps} where
++ \axiom{gps} is a list of the polynomial \axiom{p} in \axiom{ps}
++ such that \axiom{pred?(p)} holds for every \axiom{pred?} in \axiom{lpred?}
++ and \axiom{bps} are the other ones.
quasiMonicPolynomials : LP -> Record(goodPols:LP,badPols:LP)
++ \axiom{quasiMonicPolynomials(lp)} returns \axiom{qmps,nqmps} where
++ \axiom{qmps} is a list of the quasi-monic polynomials in \axiom{lp}
++ and \axiom{nqmps} are the other ones.
univariate? : P -> B
++ \axiom{univariate?(p)} returns true iff \axiom{p} involves one and
++ only one variable.
univariatePolynomials : LP -> Record(goodPols:LP,badPols:LP)
++ \axiom{univariatePolynomials(lp)} returns \axiom{ups,nups} where
++ \axiom{ups} is a list of the univariate polynomials,
++ and \axiom{nups} are the other ones.
linear? : P -> B
++ \axiom{linear?(p)} returns true iff \axiom{p} does not lie
++ in the base ring \axiom{R} and has main degree \axiom{1}.
linearPolynomials : LP -> Record(goodPols:LP,badPols:LP)
CHAPTER 17. CHAPTER P

++ \texttt{linearPolynomials(lp)} returns \texttt{\{lps, nlps\}} where
++ \texttt{lps} is a list of the linear polynomials in \texttt{lp},
++ and \texttt{\{nlps\}} are the other ones.

\textbf{bivariate? : P -> B}
++ \texttt{bivariate?(p)} returns true iff \texttt{\{p\}} involves two and
++ only two variables.

\textbf{bivariatePolynomials : LP -> Record(goodPols:LP, badPols:LP)}
++ \texttt{\{bivariatePolynomials(lp)\}} returns \texttt{\{bps, nbps\}} where
++ \texttt{\{bps\}} is a list of the bivariate polynomials,
++ and \texttt{\{nbps\}} are the other ones.

\textbf{removeRoughlyRedundantFactorsInPols : (LP, LP) -> LP}
++ \texttt{\{removeRoughlyRedundantFactorsInPols(lp, lf)\}} returns
++ \texttt{\{newlp\}} where \texttt{\{newlp\}} is obtained from \texttt{\{lp\}}
++ by removing in every polynomial \texttt{\{p\}} of \texttt{\{lp\}}
++ any occurrence of a polynomial \texttt{\{f\}} in \texttt{\{lf\}}.
++ This may involve a lot of exact-quotients computations.

\textbf{removeRoughlyRedundantFactorsInPols : (LP, LP, B) -> LP}
++ \texttt{\{removeRoughlyRedundantFactorsInPols(lp, lf, opt)\}} returns
++ the same as \texttt{\{removeRoughlyRedundantFactorsInPols(lp, lf)\}}
++ if \texttt{\{opt\}} is \texttt{\{false\}} and if the previous operation
++ does not return any non null and constant polynomial,
++ else return \texttt{\{[1]\}}.

\textbf{removeRoughlyRedundantFactorsInPol : (P, LP) -> P}
++ \texttt{\{removeRoughlyRedundantFactorsInPol(p, lf)\}} returns the same as
++ \texttt{\{removeRoughlyRedundantFactorsInPols([p], lf, true)\}}

\textbf{intReduce : LP -> LP}
++ \texttt{\{intReduce(lp)\}} returns \texttt{\{lq\}} such that \texttt{\{lp\}}
++ and \texttt{\{lq\}} generate the same ideal and no polynomial
++ in \texttt{\{lq\}} is reducible by the others in the sense
++ of Groebner bases. Since no assumptions are required
++ the result may depend on the ordering the reductions are
++ performed.

\textbf{roughBasicSet : LP -> Union(Record(bas:T, top:LP), "failed")}
++ \texttt{\{roughBasicSet(lp)\}} returns the smallest (with Ritt-Wu
++ ordering) triangular set contained in \texttt{\{lp\}}.

\textbf{crushedSet : LP -> LP}
++ \texttt{\{crushedSet(lp)\}} returns \texttt{\{lq\}} such that \texttt{\{lp\}} and
++ \texttt{\{lq\}} generate the same ideal and no rough basic
++ sets reduce (in the sense of Groebner bases) the other
++ polynomials in \texttt{\{lq\}}.

\textbf{rewriteSetByReducingWithParticularGenerators : (LP, (P -> B), ((P,P) -> B), ((P,P) -> P)) -> LP}
++ \texttt{\{rewriteSetByReducingWithParticularGenerators(lp, pred?, redOp?, redOp)\}}
++ returns \texttt{\{lq\}} where \texttt{\{lq\}} is computed by the following
++ algorithm. Chose a basic set w.r.t. the reduction-test \texttt{\{redOp?\}}
++ among the polynomials satisfying property \texttt{\{pred?\}},
++ if it is empty then leave, else reduce the other polynomials by
++ this basic set w.r.t. the reduction-operation \texttt{\{redOp\}}.
++ Repeat while another basic set with smaller rank can be computed.
++ See code. If \texttt{\{pred?\}} is \texttt{\{quasiMonic?\}} the ideal is unchanged.

\textbf{rewriteIdealWithQuasiMonicGenerators : (LP, (P,P) -> B), ((P,P) -> P)) -> LP}
++ \texttt{rewriteIdealWithQuasiMonicGenerators(lp,redOp?,redOp)} returns
++ \texttt{lq} where \texttt{lq} and \texttt{lp} generate
++ the same ideal in \texttt{"R"^(-1) P} and \texttt{lp}
++ has rank not higher than the one of \texttt{lp}.
++ Moreover, \texttt{lq} is computed by reducing \texttt{lp}
++ w.r.t. some basic set of the ideal generated by
++ the quasi-monic polynomials in \texttt{lp}.

if \texttt{R} has \texttt{GcdDomain}
then

\texttt{squareFreeFactors : P \rightarrow LP}
++ \texttt{squareFreeFactors(p)} returns the square-free factors of \texttt{p}
++ over \texttt{R}

\texttt{univariatePolynomialsGcds : LP \rightarrow LP}
++ \texttt{univariatePolynomialsGcds(lp)} returns \texttt{lg} where
++ \texttt{lg} is a list of the gcds of every pair in \texttt{lp}
++ of univariate polynomials in the same main variable.

\texttt{univariatePolynomialsGcds : (LP,B) \rightarrow LP}
++ \texttt{univariatePolynomialsGcds(lp,opt)} returns the same as
++ \texttt{univariatePolynomialsGcds(lp)} if \texttt{opt} is
++ \texttt{false} and if the previous operation does not return
++ any non null and constant polynomial, else return \texttt{axiom\{1\}}.

\texttt{removeRoughlyRedundantFactorsInContents : (LP, LP) \rightarrow LP}
++ \texttt{removeRoughlyRedundantFactorsInContents(lp,lf)} returns
++ \texttt{newlp} where \texttt{newlp} is obtained from \texttt{lp}
++ by removing in the content of every polynomial of \texttt{lp}
++ any occurrence of a polynomial \texttt{f} in \texttt{lf}. Moreover,
++ squares over \texttt{R} are first removed in the content
++ of every polynomial of \texttt{lp}.

\texttt{removeRedundantFactorsInContents : (LP, LP) \rightarrow LP}
++ \texttt{removeRedundantFactorsInContents(lp,lf)} returns \texttt{newlp}
++ where \texttt{newlp} is obtained from \texttt{lp} by removing
++ in the content of every polynomial of \texttt{lp} any non trivial
++ factor of any polynomial \texttt{f} in \texttt{lf}. Moreover,
++ squares over \texttt{R} are first removed in the content
++ of every polynomial of \texttt{lp}.

\texttt{removeRedundantFactorsInPols : (LP, LP) \rightarrow LP}
++ \texttt{removeRedundantFactorsInPols(lp,lf)} returns \texttt{newlp}
++ where \texttt{newlp} is obtained from \texttt{lp} by removing
++ in every polynomial \texttt{p} of \texttt{lp} any non trivial
++ factor of any polynomial \texttt{f} in \texttt{lf}. Moreover,
++ squares over \texttt{R} are first removed in every
++ polynomial \texttt{lp}.

if (\texttt{R} has \texttt{EuclideanDomain}) and (\texttt{R} has \texttt{CharacteristicZero})
then

\texttt{irreducibleFactors : LP \rightarrow LP}
++ \texttt{irreducibleFactors(lp)} returns \texttt{lf} such that if
++ \texttt{lp} = \texttt{[p_1,...,p_n]} and \texttt{lf} = \texttt{[f_1,...,f_m]} then
++ \texttt{p_1*p_2*...*p_n=0} means \texttt{f_1*f_2*...*f_m=0}, and the \texttt{\{f_i\}}
++ are irreducible over \texttt{R} and are pairwise distinct.

\texttt{lazyIrreducibleFactors : LP \rightarrow LP}
CHAPTER 17. CHAPTER P

++ \texttt{lazyIrreducibleFactors(lp)} returns \texttt{lf} such that if
++ \texttt{lp = [p1,...,pn]} and \texttt{lf = [f1,...,fm]} then
++ \texttt{p1*p2*...*pn=0} means \texttt{f1*f2*...*fm=0}, and the \texttt{fi}
++ are irreducible over \texttt{R} and are pairwise distinct.
++ The algorithm tries to avoid factorization into irreducible
++ factors as far as possible and makes previously use of gcd
++ techniques over \texttt{R}.

++ \texttt{removeIrreducibleRedundantFactors(lp, lq)} returns the same
++ as \texttt{irreducibleFactors(concat(lp, lq))} assuming
++ that \texttt{irreducibleFactors(lp)} returns \texttt{lp}
++ up to replacing some polynomial \texttt{pj} in \texttt{lp}
++ by some polynomial \texttt{qj} associated to \texttt{pj}.

Exports ==> with

denomRicDE: L -> UP
++ denomRicDE(op) returns a polynomial \spad{d} such that any rational
++ solution of the associated Riccati equation of \spad{op y = 0} is
++ of the form \spad{p/d + q'/q + r} for some polynomials p and q
++ and a reduced r. Also, \spad{deg(p) < deg(d)} and \{gcd(d,q) = 1\}.

leadingCoefficientRicDE: L -> List REC
++ leadingCoefficientRicDE(op) returns
++ \spad{[[m1, p1], [m2, p2], ... , [mk, pk]]} such that the polynomial
++ part of any rational solution of the associated Riccati equation of
++ \spad{op y = 0} must have degree mj for some j, and its leading
++ coefficient is then a zero of pj. In addition,\spad{m1>m2> ... >mk}.

coefficientCoefficientRicDE: (L, UP -> List F) -> List CNT
++ coefficientCoefficientRicDE(op, ric) returns
++ \spad{[[a1, L1], [a2, L2], ... , [ak, Lk]]} such that any rational
++ solution with no polynomial part of the associated Riccati equation of
++ \spad{op y = 0} must be one of the ai's in which case the equation for
++ \spad{z = y e^{-\operatorname{int} ai}} is \spad{Li z = 0}.
++ \spad{ric} is a Riccati equation solver over \spad{F}, whose input
++ is the associated linear equation.

polyRicDE: (L, UP -> List F) -> List POL
++ polyRicDE(op, zeros) returns
++ \spad{[[p1, L1], [p2, L2], ... , [pk, Lk]]} such that the polynomial
++ part of any rational solution of the associated Riccati equation of
++ \spad{op y=0} must be one of the pi's (up to the constant coefficient),
++ in which case the equation for \spad{z=y e^{-\operatorname{int} p}} is \spad{Li z = 0}.
++ \spad{zeros} is a zero finder in \spad{UP}.

singRicDE: (L, (UP, UP2) -> List UP, UP -> Factored UP) -> List FRC
++ singRicDE(op, zeros, ezfactor) returns
++ \spad{[[f1, L1], [f2, L2], ... , [fk, Lk]]} such that the singular
++ part of any rational solution of the associated Riccati equation of
++ \spad{op y=0} must be one of the fi's (up to the constant coefficient),
++ in which case the equation for \spad{z=y e^{-\operatorname{int} p}} is \spad{Li z=0}.
++ \spad{zeros(C(x),H(x,y))} returns all the \spad{P_i(x)}'s such that
++ \spad{H(x,P_i(x)) = 0} modulo \spad{C(x)}.
++ Argument \spad{ezfactor} is a factorisation in \spad{UP},
++ not necessarily into irreducibles.

--- package PSEUDLIN PseudoLinearNormalForm ---

)abbrev package PSEUDLIN PseudoLinearNormalForm
++ Author: Bruno Zuercher
++ Date Created: November 1993
++ Date Last Updated: 12 April 1994
++ Description:
++ PseudoLinearNormalForm provides a function for computing a block-companion
++ form for pseudo-linear operators.

PseudoLinearNormalForm(K:Field): Exports == Implementation where
  ER ==> Record(C: Matrix K, g: Vector K)
  REC ==> Record(R: Matrix K, A: Matrix K, Ainv: Matrix K)

Exports == with
  normalForm: (Matrix K, Automorphism K, K -> K) -> REC
    ++ normalForm(M, sig, der) returns \spad{[R, A, A^{-1}]} such that
    ++ the pseudo-linear operator whose matrix in the basis \spad{y} is
    ++ \spad{M} had matrix \spad{R} in the basis \spad{z = A y}.
    ++ \spad{der} is a \spad{sig}-derivation.
  changeBase: (Matrix K, Matrix K, Automorphism K, K -> K) -> Matrix K
    ++ changeBase(M, A, sig, der): computes the new matrix of a pseudo-linear
    ++ transform given by the matrix M under the change of base A
companionBlocks: (Matrix K, Vector K) -> List ER
++ companionBlocks(m, v) returns \spad{[[C_1, g_1],..., [C_k, g_k]]}
++ such that each \spad{C_i} is a companion block and
++ \spad{m = diagonal(C_1,...,C_k)}.

Implementation == add

PseudoRemainderSequence examples
================================================================================

The package constructor PseudoRemainderSequence provides
efficient algorithms by Lionel Ducos (University of Poitiers, France)
for computing sub-resultants. This leads to a speed up in many places
in Axiom where sub-resultants are computed (polynomial system solving,
algebraic factorization, integration).

This package contains some functions from improvements of the
subresultants algorithm.

++ Author: Manuel Bronstein
++ Date Created: 27 May 1988
++ Date Last Updated: 24 June 1994
++ Description:
  ++ Integration of pure algebraic functions;
  ++ This package provides functions for integration, limited integration,
  ++ extended integration and the risch differential equation for
  ++ pure algebraic integrands;

PureAlgebraicIntegration(R, F, L): Exports == Implementation where
  R: Join(GcdDomain,RetractableTo Integer,OrderedSet, CharacteristicZero,
     LinearlyExplicitRingOver Integer)
  F: Join(FunctionSpace R, AlgebraicallyClosedField,
     TranscendentalFunctionCategory)
  L: SetCategory

SY  ==> Symbol
N  ==> NonNegativeInteger
K  ==> Kernel F
P  ==> SparseMultivariatePolynomial(R, K)
UP  ==> SparseUnivariatePolynomial F
RF  ==> Fraction UP
UPUP  ==> SparseUnivariatePolynomial RF
IR  ==> IntegrationResult F
IR2 ==> IntegrationResultFunctions2(curve, F)
ALG ==> AlgebraicIntegrate(R, F, UP, UPUP, curve)
LDALG ==> LinearOrdinaryDifferentialOperator1 curve
RDALG ==> PureAlgebraicLODE(F, UP, UPUP, curve)
LOG ==> Record(coeff:F, logand:F)
REC ==> Record(particular:U1, basis:List F)
CND ==> Record(left:UP, right:UP)
CHV ==> Record(int:UPUP, left:UP, right:UP, den:RF, deg:N)
U1 ==> Union(F, "failed")
U2 ==> Union(Record(ratpart:F, coeff:F),"failed")
U3 ==> Union(Record(mainpart:F, limitedlogs:List LOG), "failed")
FAIL==> error "failed - cannot handle that integrand"

Exports ==> with
  palgint : (F, K, K) -> IR
    ++ palgint(f, x, y) returns the integral of \( f(x,y)dx \)
    ++ where \( y \) is an algebraic function of \( x \).
  palgextint: (F, K, K, F) -> U2
    ++ palgextint(f, x, y, g) returns functions \( \{h, c\} \) such that
    ++ \( dh/dx = f(x,y) - c g \), where \( y \) is an algebraic function of \( x \);
    ++ returns "failed" if no such functions exist.
  palglimint: (F, K, K, List F) -> U3
    ++ palglimint(f, x, y, \{u1,...,un\}) returns functions
    ++ \( \{h,[[ci, ui]]\} \) such that the ui's are among \( \{u1,...,un\} \)
    ++ and \( d(h + \sum(ci \log(ui)))/dx = f(x,y) \) if such functions exist,
    ++ "failed" otherwise;
    ++ \( y \) is an algebraic function of \( x \).
  palgRDE : (F, F, F, K, K, (F, F, SY) -> U1) -> U1
    ++ palgRDE(nfp, f, g, x, y, foo) returns a function \( z(x,y) \)
    ++ such that \( dz/dx + n * df/dx z(x,y) = g(x,y) \) if such a \( z \) exists,
    ++ "failed" otherwise;
    ++ \( y \) is an algebraic function of \( x \);
    ++ \( \{foo(a, b, x)\} \) is a function that solves
    ++ \( du/dx + n * da/dx u(x) = u(x) \)
    ++ for an unknown \( \{spad{u}(x)\} \) not involving \( y \).
    ++ \( \{spad{nfp}\} \) is \( \{spad{n * df/dx}\} \).

if L has LinearOrdinaryDifferentialOperatorCategory F then
  palgLODE: (L, F, K, K, SY) -> REC
    ++ palgLODE(op, g, kx, y, x) returns the solution of \( \text{spad{op}} f = g \).
    ++ \( y \) is an algebraic function of \( x \).

QuasiAlgebraicSet2 examples

QuasiAlgebraicSet2 adds a function radicalSimplify which uses IdealDecompositionPackage to simplify the representation of a quasi-algebraic set.

A quasi-algebraic set is the intersection of a Zariski closed set, defined as the common zeros of a given list of polynomials (the defining polynomials for equations), and a principal Zariski open set, defined as the complement of the common zeros of a polynomial f (the defining polynomial for the inequation).

Quasi-algebraic sets are implemented in the domain QuasiAlgebraicSet, where two simplification routines are provided: idealSimplify and simplify.

The function radicalSimplify is added for comparison study only.

Because the domain IdealDecompositionPackage provides facilities for computing with radical ideals, it is necessary to restrict the ground ring to the domain Fraction Integer, and the polynomial ring to be of type DistributedMultivariatePolynomial.

The routine radicalSimplify uses these to compute groebner basis of radical ideals and is inefficient and restricted when compared to the two in QuasiAlgebraicSet.

QuaternionCategoryFunctions2 examples

QuaternionCategoryFunctions2 implements functions between two quaternion domains. The function map is used by the system interpreter to coerce between quaternion types.

The package QuaternionCategoryFunctions2 provides a function map to convert an expression in Quaternion(R) to an expression in Quaternion(S) using the function f.

q := quatern(2/11,-8,3/4,1)

2 3
-- 8i + j + k
11 4

Type: Quaternion Fraction Integer
f(a:Fraction Integer):Complex Fraction Integer == a::Complex Fraction Integer
   Function declaration f : Fraction Integer -> Complex Fraction Integer has been added to workspace.
       Type: Void

map(f,q)
   Compiling function f with type Fraction Integer -> Complex Fraction Integer

\[
\begin{array}{c}
\frac{2}{11} \quad \frac{3}{4} \\
\frac{-8i + - j + k}{11}
\end{array}
\]

Type: Quaternion Complex Fraction Integer

++ Author: P.Gianni
++ Date Created: Summer 1987
++ Date Last Updated: October 1992
++ Description:
++ Package for the computation of eigenvalues and eigenvectors.
++ This package works for matrices with coefficients which are
++ rational functions over the integers.
++ (see \spadtype{Fraction Polynomial Integer}).
++ The eigenvalues and eigenvectors are expressed in terms of radicals.

RadicalEigenPackage() : C == T

where

R ==> Integer
P ==> Polynomial R
F ==> Fraction P
RE ==> Expression R
SE ==> Symbol()
M ==> Matrix(F)
MRE ==> Matrix(RE)
ST ==> SuchThat(SE,P)
NNI ==> NonNegativeInteger

EigenForm ==> Record(eigval:Union(F,ST),eigmult:NNI,eigvec:List(M))
RadicalForm ==> Record(radval:RE,radmult:Integer,radvect:List(MRE))

C == with

radicalEigenvectors : M -> List(RadicalForm)

++ radicalEigenvectors(m) computes
++ the eigenvalues and the corresponding eigenvectors of the
++ matrix m;
++ when possible, values are expressed in terms of radicals.

radicalEigenvector : (RE,M) -> List(MRE)

++ radicalEigenvector(c,m) computes the eigenvector(s) of the
++ matrix m corresponding to the eigenvalue c;
++ when possible, values are
++ expressed in terms of radicals.

radicalEigenvalues : M -> List RE

++ radicalEigenvalues(m) computes the eigenvalues of the matrix m;
++ when possible, the eigenvalues are expressed in terms of radicals.

eigenMatrix : M -> Union(MRE,"failed")

++ eigenMatrix(m) returns the matrix b
++ such that \spad{b*m*(inverse b)} is diagonal,
++ or "failed" if no such b exists.

normalise : MRE -> MRE

++ normalise(v) returns the column
++ vector v
++ divided by its euclidean norm;
++ when possible, the vector \( v \) is expressed in terms of radicals.

\[ \text{gramschmidt} : \text{List(MRE)} \rightarrow \text{List(MRE)} \]
++ \text{gramschmidt(lv)} converts the list of column vectors \( \text{lv} \) into
++ a set of orthogonal column vectors
++ of euclidean length 1 using the Gram-Schmidt algorithm.

\[ \text{orthonormalBasis} : \text{M} \rightarrow \text{List(MRE)} \]
++ \text{orthonormalBasis(m)} returns the orthogonal matrix \( b \) such that
++ \( \text{spad}(b*m*(\text{inverse} \ b)) \) is diagonal.
++ Error: if \( m \) is not a symmetric matrix.

Factorization of extended polynomials with rational coefficients.
This package implements factorization of extended polynomials whose
coefficients are rational numbers. It does this by taking the lcm of
the coefficients of the polynomial and creating a polynomial with
integer coefficients. The algorithm in GaloisGroupFactorizer is then
used to factor the integer polynomial. The result is normalized with
respect to the original lcm of the denominators.

RationalFunctionSum examples
====================================================================
Computes sums of rational functions.
There are 4 different forms of the sum operator in this domain.
They are variations of the types of the input
sum(i::Polynomial(Integer),variable(i=1..n))

\[
\frac{2}{12} \left( \frac{6i - 6i + 1}{12} \right)
\]
We can compute the sum form on part at a time to see what happens. First, we make a SegmentBinding(Polynomial(Integer)): 

\[ s := i = 1..n \]

\[ i = 1..n \]

We pick out the upper and lower bounds of the segment:

\[ \text{hiseg} := \text{high(segment(s))} \]

\[ n \]

\[ \text{loseg} := \text{low(segment(s))} \]

\[ 1 \]

We pick out the variable from the segment:

\[ v := \text{variable s} \]
We create a polynomial we wish to sum:

\[ p := i::\text{Polynomial}(\text{Integer}) \]

And we create the sum for that polynomial:

\[ f := \text{sum}(p, v) \]

\[ \frac{2}{12} \frac{6i - 6i + 1}{12} \]

The new evaluate it at the upper endpoint:

\[ t1 := \text{eval}(f, v, (1 + \text{hiseg})) \]

\[ \frac{2}{12} \frac{6n + 6n + 1}{12} \]

And the lower endpoint:

\[ t2 := \text{eval}(f, v, \text{loseg}) \]

\[ \frac{1}{12} \]

And we take the difference of the endpoints:

\[ t1 - t2 \]

\[ \frac{2}{2} \frac{n + n}{2} \]

—— INTRAT.dotabb ——
package **RINTERP** RationalInterpolation

**Introduction**

This file contains a crude naïve implementation of rational interpolation, where the coefficients of the rational function are in any given field.

**Questions and Outlook**

- Maybe this file should be joined with pinterp.spad, where polynomial Lagrange interpolation is implemented. I have a second version that parallels the structure of pinterp.spad closely.

- There are probably better ways to implement rational interpolation. Maybe [http://www.cs.ucsb.edu/~omer/personal/abstracts/rational.html](http://www.cs.ucsb.edu/~omer/personal/abstracts/rational.html) contains something useful, but I don’t know.

- Comments welcome!

`RATIONALINTERPOLATION(RINTERP)`

`PFECAT`
xx: Symbol
F: Field
Exports == with
    interpolate: (List F, List F, NonNegativeInteger, NonNegativeInteger) -> Fraction Polynomial F

The implementation sets up a system of linear equations and solves it.

— package RINTERP RationalInterpolation —

Implementation == add
    interpolate(xlist, ylist, m, k) ==

First we check whether we have the right number of points and values. Clearly the number of points and the number of values must be identical. Note that we want to determine the numerator and denominator polynomials only up to a factor. Thus, we want to determine \( m + k + 1 \) coefficients, where \( m \) is the degree of the polynomial in the numerator and \( k \) is the degree of the polynomial in the denominator.

In fact, we could also leave, for example, \( k \) unspecified and determine it as \( k = \#\text{xlist} - m - 1 \). I don’t know whether this would be better.

— package RINTERP RationalInterpolation —

\[
\#\text{xlist} ^= \#\text{ylist} =>
\]
\[
\text{error "Different number of points and values."}
\]
\[
\#\text{xlist} ^= m + k + 1 =>
\]
\[
\text{error "Wrong number of points"}
\]

The next step is to set up the matrix. Suppose that our numerator polynomial is \( p(x) = a_0 + a_1 x + \ldots + a_m x^m \) and that our denominator polynomial is \( q(x) = b_0 + b_1 x + \ldots + b_m x^m \). Then we have the following equations, writing \( n \) for \( m + k + 1 \):

\[
p(x_1) - y_1 q(x_1) = a_0 + a_1 x_1 + \ldots + a_m x_1^m - y_1 (b_0 + b_1 x_1 + \ldots + b_m x_1^m) = 0
\]
\[
p(x_2) - y_2 q(x_2) = a_0 + a_1 x_2 + \ldots + a_m x_2^m - y_2 (b_0 + b_1 x_2 + \ldots + b_m x_2^m) = 0
\]
\[
\vdots
\]
\[
p(x_n) - y_n q(x_n) = a_0 + a_1 x_n + \ldots + a_m x_n^m - y_n (b_0 + b_1 x_n + \ldots + b_m x_n^m) = 0
\]
This can be written as

\[
\begin{bmatrix}
1 & x_1 & \cdots & x_1^m & -y_1 & -y_1 x_1 & \cdots & -y_1 x_1^k \\
1 & x_2 & \cdots & x_2^m & -y_2 & -y_2 x_2 & \cdots & -y_2 x_2^k \\
\vdots \\
1 & x_n & \cdots & x_n^m & -y_n & -y_n x_n & \cdots & -y_n x_n^k \\
\end{bmatrix}
\begin{bmatrix}
a_0 \\
a_1 \\
\vdots \\
a_m \\
b_0 \\
b_1 \\
\vdots \\
b_k \\
\end{bmatrix}
= 0
\]

We generate this matrix columnwise:

```
--- package RINTERP RationalInterpolation ---

tempvec: List F := [1 for i in 1..(m+k+1)]
collist: List List F := cons(tempvec,
   [[tempvec := [tempvec.i * xlist.i _
   for i in 1..(m+k+1)] _
   for j in 1..max(m,k)]]
collist := append([collist.j for j in 1..(m+1)], _
   [[- collist.j.i * ylist.i for i in 1..(m+k+1)] _
   for j in 1..(k+1)]
```

Now we can solve the system:

```
--- package RINTERP RationalInterpolation ---

res: List Vector F := nullSpace((transpose matrix collist) _
   ::Matrix F)
```

Note that it may happen that the system has several solutions. In this case, some of the
data points may not be interpolated correctly. However, the solution is often still useful,
thus we do not signal an error.

```
--- package RINTERP RationalInterpolation ---

if #res=1 then output("Warning: unattainable points!" _
   ::OutputForm)$OutputPackage
```

In this situation, all the solutions will be equivalent, thus we can always simply take the first one:
Finally, we generate the rational function:

— package RINTERP RationalInterpolation —

\[
\frac{\text{reduce}(\_+), \text{reslist}.1}{\text{reduce}(\_+), \text{reslist}.2}
\]

)abbrev package RURPK RationalUnivariateRepresentationPackage
++ Author: Marc Moreno Maza
++ Date Created: 01/1999
++ Date Last Updated: 23/01/1999
++ Description:
++ A package for computing the rational univariate representation
++ of a zero-dimensional algebraic variety given by a regular
++ triangular set. This package is essentially an interface for the
++ \spadtype{InternalRationalUnivariateRepresentationPackage} constructor.
++ It is used in the \spadtype{ZeroDimensionalSolvePackage}
++ for solving polynomial systems with finitely many solutions.

RationalUnivariateRepresentationPackage(R,ls): Exports == Implementation where
  R : Join(EuclideanDomain,CharacteristicZero)
  ls: List Symbol
  N ==> NonNegativeInteger
  Z ==> Integer
  P ==> Polynomial R
  LP ==> List P
  U ==> SparseUnivariatePolynomial(R)
  RUR ==> Record(complexRoots: U, coordinates: LP)

Exports == with

  rur: (LP,Boolean) -> List RUR
  ++ \spad{rur(lp,univ?)} returns a rational univariate representation
  ++ of \spad{lp}. This assumes that \spad{lp} defines a regular
  ++ triangular \spad{ts} whose associated variety is zero-dimensional
  ++ over \spad{R}. \spad{rur(lp,univ?)} returns a list of items
  ++ \spad{[u,lc]} where \spad{u} is an irreducible univariate polynomial
and each \texttt{\texttt{c}} in \texttt{\texttt{lc}} involves two variables: one from \texttt{\texttt{ls}},

the coordinate of \texttt{\texttt{c}}, and an extra variable which

represents any root of \texttt{\texttt{u}}. Every root of \texttt{\texttt{u}} leads to

two tuple of values for the coordinates of \texttt{\texttt{lc}}. Moreover,

a point \texttt{\texttt{x}} belongs to the variety associated with \texttt{\texttt{lp}} iff

there exists an item \texttt{\texttt{spad}}\{(\texttt{u,lc})\} in \texttt{\texttt{spad}}\{(\texttt{lp,univ?})\} and

a root \texttt{\texttt{r}} of \texttt{\texttt{u}} such that \texttt{\texttt{spad}}\{(\texttt{x})\} is given by the

two tuple of values for the coordinates of \texttt{\texttt{lc}} evaluated at \texttt{\texttt{r}}.

If \texttt{\texttt{spad}}\{(\texttt{univ?})\} is \texttt{\texttt{spad}}\{(\texttt{true})\} then each polynomial \texttt{\texttt{spad}}\{(\texttt{c})\}

will have a constant leading coefficient w.r.t. its coordinate.

See the example which illustrates the \texttt{\texttt{spadtype}}\{ZeroDimensionalSolvePackage\}

package constructor.

package POLUTIL RealPolynomialUtilitiesPackage

This file describes the Real Closure 1.0 package which consists of different packages, categories and domains.

The package RealPolynomialUtilitiesPackage which receives a field and a univariate polynomial domain with coefficients in the field. It computes some simple functions such as Strum and Sylvester sequences.

The category RealRootCharacterizationCategory provides abstract functionalities to work with "real roots" of univariate polynomials. These resemble variables with some functionalities needed to compute important operations.

RealClosedField is a category with provides common operations available over real closed fields. These include finding all the roots of univariate polynomial, taking square roots, ...

CAVEATS
Since real algebraic expressions are stored as depending on "real roots" which are managed like variables, there is an ordering on these. This ordering is dynamical in the sense that any new algebraic takes precedence over older ones. In particular every creation function raises a new "real root". This has the effect that when you type something like sqrt(2) + sqrt(2) you have two new variables which happen to be equal. To avoid this name the expression such as in s2 := sqrt(2) ; s2 + s2

Also note that computing times depend strongly on the ordering you implicitly provide. Please provide algebraics in the order which most natural to you.

LIMITATIONS
The file reclos.input show some basic use of the package. This packages uses algorithms which are published in [1] and [2] which are based on field arithmetics, in particular for polynomial gcd related algorithms. This can be quite slow for high degree polynomials and subresultants methods usually work best. Beta versions of the package try to use these techniques in a better way and work significantly faster. These are mostly based on unpublished algorithms and cannot be distributed. Please contact the author if you have a particular problem to solve or want to use these versions.

Be aware that approximations behave as post-processing and that all computations are done exactly. They can thus be quite time consuming when depending on several "real roots".

-- RetractableTo Symbol, PartialDifferentialRing Symbol)

Exports == with

evalRec: (BasicOperator, Symbol, F, F, F, List F) -> F
++ \spad{evalRec(u, dummy, n, n0, eq, values)} creates an expression that
++ stands for u(n0), where u(n) is given by the equation eq. However, for
++ technical reasons the variable n has to be replaced by a dummy
++ variable dummy in eq. The argument values specifies the initial values
++ of the recurrence u(0), u(1),...
++ For the moment we don't allow recursions that contain u inside of
++ another operator.

evalADE: (BasicOperator, Symbol, F, F, F, List F) -> F
++ \spad{evalADE(f, dummy, x, n, eq, values)} creates an expression that
 CHAPTER 19. CHAPTER R

 gets for the coefficient of x^n in the Taylor expansion of f(x),
 where f(x) is given by the functional equation eq. However, for
 technical reasons the variable x has to be replaced by a dummy
 variable dummy in eq. The argument values specifies the first few
 Taylor coefficients.

 \spad{getEq f} returns the defining equation, if f represents the
 coefficient of an ADE or a recurrence.

 \spad{getOp f}, if f represents the coefficient of a recurrence or
 ADE, returns the operator representing the solution

 \getchunk{implementation: RecurrenceOperator}

 Defining new operators

 We define two new operators, one for recurrences, the other for functional equations. The
 operators for recurrences represents the n^th term of the corresponding sequence, the other
 the coefficient of x^n in the Taylor series expansion.

 — implementation: RecurrenceOperator —

 oprecur := operator("rootOfRec":::Symbol)$BasicOperator
 opADE := operator("rootOfADE":::Symbol)$BasicOperator

 setProperty(oprecur, "%dummyVar", 2 pretend None)
 setProperty(opADE, "%dummyVar", 2 pretend None)
Setting these properties implies that the second and third arguments of oprecur are dummy variables and affects `tower$ES`: the second argument will not appear in `tower$ES`, if it does not appear in any argument but the first and second. The third argument will not appear in `tower$ES`, if it does not appear in any other argument. (%defsum is a good example)

The arguments of the two operators are as follows:

1. eq, i.e. the vanishing expression

    — implementation: RecurrenceOperator —

        `eqAsF`: `List F -> F`
        `eqAsF 1 == 1.1`

          —

2. dummy, a dummy variable to make substitutions possible

    — implementation: RecurrenceOperator —

        `dummy`: `List F -> Symbol`
        `dummy 1 == retract(1.2)@Symbol`

        `dummyAsF`: `List F -> F`
        `dummyAsF 1 == 1.2`

          —

3. the variable for display

    — implementation: RecurrenceOperator —

        `displayVariable`: `List F -> F`
        `displayVariable 1 == 1.3`

          —

4. `operatorName(argument)`

    — implementation: RecurrenceOperator —

        `operatorName`: `List F -> BasicOperator`
        `operatorName 1 == operator(kernels(1.4).1)`

        `operatorNameAsF`: `List F -> F`
        `operatorNameAsF 1 == 1.4`

        `operatorArgument`: `List F -> F`
        `operatorArgument 1 == argument(kernels(1.4).1).1`
Concerning rootOfADE, note that although we have arg as argument of the operator, it is intended to indicate the coefficient, not the argument of the power series.

5. values in reversed order.

- rootOfRec: maybe values should be preceded by the index of the first given value. Currently, the last value is interpreted as \( f(0) \).
- rootOfADE: values are the first few coefficients of the power series expansion in order.

| implementation: RecurrenceOperator |

| initialValues: List F -> List F |
| initialValues 1 == rest(1, 4) |

Recurrences

Extracting some information from the recurrence

We need to find out whether we can determine the next term of the sequence, and how many initial values are necessary.

| implementation: RecurrenceOperator |

```lisp
if R has Ring then
  getShiftRec(op: BasicOperator, f: Kernel F, n: Symbol) : Union(Integer, "failed") ==
    a := argument f
    if every?(z +-> freeOf?(z, n::F), a) then return 0
    if #a ~= 1 then error "RECOP: operator should have only one argument"
    p := univariate(a.1, retract(n::F)@Kernel(F))
    if denominator p ~= 1 then return "failed"
    num := numerator p
    if degree num = 1 and coefficient(num, 1) = 1
      and every?(z +-> freeOf?(z, n::F), coefficients num)
      then return retractIfCan(coefficient(num, 0))
      else return "failed"
```
-- if the recurrence is of the form
-- $p(n, f(n+m-o), f(n+m-o+1), \ldots, f(n+m)) = 0$
-- in which case shiftInfoRec returns $[m, o, f(n+m)]$.

shiftInfoRec(op: BasicOperator, argsym: Symbol, eq: F):
  Record(max: Union(Integer, "failed"),
         ord: Union(Integer, "failed"),

— implementation: RecurrenceOperator —

irecur: List F -> F
irecur l ==
evalRec(operatorName l,
    dummy l, displayVariable l,
    operatorArgument l, eqAsF l, initialValues l)
evaluate(oprecur, irecur)$BasicOperatorFunctions1(F)

Displaying a recurrence relation

— implementation: RecurrenceOperator —
Functional Equations

Determining the number of initial values for ADE's

We use Joris van der Hoeven’s instructions for ADE's. Given \( Q = p(f, f', \ldots, f^{(r)}) \) we first need to differentiate \( Q \) with respect to \( f^{(i)} \) for \( i \in \{0, 1, \ldots, r\} \), plug in the given truncated power series solution and determine the valuation.

— NOTYET implementation: RecurrenceOperator —

```
getValuation(op, argsym, eq, maxorder, values): Integer ==
max: Integer := -1;
ker: Kernel F
for i in 0..maxorder repeat
  ker := D(op(argsym), argsym, i)::Kernel F
  pol := univariate(eq, ker)
  dif := D pol
  ground numer(dif.D(op(argsym), argsym, i))
```
Extracting some information from the functional equation

getOrder returns the maximum derivative of op occurring in f.

--- implementation: RecurrenceOperator ---

```pascal
getOrder(op: BasicOperator, f: Kernel F): NonNegativeInteger ==
res: NonNegativeInteger := 0
  g := f
while is?(g, %diff) repeat
  g := kernels(argument(g).1).1
  res := res+1
if is?(g, op) then res else 0
```

--- RegularSetDecompositionPackage.help ---

====================================================================
RegularSetDecompositionPackage examples
====================================================================

A package providing a new algorithm for solving polynomial systems by
means of regular chains. Two ways of solving are proposed: in the sense of Zariski closure (like in Kalkbrener’s algorithm) or in the sense of the regular zeros (like in Wu, Wang or Lazard methods). This algorithm is valid for any type of regular set. It does not care about the way a polynomial is added in an regular set, or how two quasi-components are compared (by an inclusion-test), or how the invertibility test is made in the tower of simple extensions associated with a regular set.

These operations are realized respectively by the domain TS and the packages QCMPACK(R,E,V,P,TS) and RSETGCD(R,E,V,P,TS).

The same way it does not care about the way univariate polynomial gcd (with coefficients in the tower of simple extensions associated with a regular set) are computed. The only requirement is that these gcd need to have invertible initials (normalized or not).

WARNING. There is no need for a user to call directly any operation of this package since they can be accessed by the domain TS. Thus, the operations of this package are not documented.

--- RepeatedSquaring.help ---

====================================================================
RepeatedSquaring examples
====================================================================

This code computes $x^n$ by repeated squaring. It takes advantage of the
law of exponents so that if $n=a\cdot b$ then

$$x^n = x^a \cdot x^b$$

It also takes advantage of the fact that $n$ has a binary representation
so that a one-bit right-shift of a number divides it by 2. Thus we get
three cases:

- $n = 1 \rightarrow x^1$
- $n$ odd \rightarrow repeatedsquare$(x\cdot x, n/2) \cdot x$
n even -> repeatedsquared(x*x, n/2)

Since each recursive call divides n by 2 the algorithm is $O(\log(n))$.

RepresentationPackage1 provides functions for representation theory for finite groups and algebras.

The package creates permutation representations and uses tensor products and its symmetric and antisymmetric components to create new representations of larger degree from given ones.

Note that instead of having parameters from Permutation this package allows list notation of permutations as well: e.g. \([1, 4, 3, 2]\) denotes permutes 2 and 4 and fixes 1 and 3.

++ of the matrix a with itself.
tensorProduct : L M R -> L M R
++ tensorProduct([a1,...ak]) calculates the list of
++ Kronecker products of each matrix ai with itself
++ for \(1 \leq i \leq k\).
++ Note that if the list of matrices corresponds to a group
++ representation (repr. of generators) of one group, then these
++ matrices correspond to the tensor product of the representation
++ with itself.

permutationRepresentation : (PERM I, I) -> M I
++ permutationRepresentation(pi,n) returns the matrix
++ \((\delta(i),\pi(i))\) (Kronecker delta) for a permutation
++ \(\pi\) of \(\{1,2,...,n\}\).

permutationRepresentation : L I -> M I
++ permutationRepresentation(pi,n) returns the matrix
++ \((\delta(i),\pi(i))\) (Kronecker delta) if the permutation
++ \(\pi\) is in list notation and permutes \(\{1,2,...,n\}\).

permutationRepresentation : (L PERM I, I) -> L M I
++ permutationRepresentation([pi1,...,pik],n) returns the list
++ of matrices \[(\delta_{i,j},\pi_1(i)),\ldots,(\delta_{i,j},\pi_k(i))\]
++ (Kronecker delta) for the permutations \(\pi_1,\ldots,\pi_k\)
++ of \(\{1,2,\ldots,n\}\).

\textbf{permutationRepresentation : L L I \rightarrow L M I}
++ permutationRepresentation([\pi_1,\ldots,\pi_k],n) returns the list
++ of matrices \[\{(\delta_{i,j},\pi_1(i)),\ldots,(\delta_{i,j},\pi_k(i))\}\]
++ if the permutations \(\pi_1,\ldots,\pi_k\) are in
++ list notation and are permuting \(\{1,2,\ldots,n\}\).

RepresentationPackage2 provides functions for working with modular representations of finite groups and algebra. The routines in this package are created, using ideas of R. Parker, (the meat-Axe) to get smaller representations from bigger ones, i.e. finding sub- and factormodules, or to show, that such the representations are irreducible.

Note that most functions are randomized functions of Las Vegas type i.e. every answer is correct, but with small probability the algorithm fails to get an answer.

public == with

  completeEchelonBasis : V V R -> M R
  ++ completeEchelonBasis(lv) completes the basis lv assumed
  ++ to be in echelon form of a subspace of R**n (n the length
  ++ of all the vectors in lv with unit vectors to a basis of
  ++ R**n. It is assumed that the argument is not an empty
  ++ vector and that it is not the basis of the 0-subspace.
  ++ Note that the rows of the result correspond to the vectors
  ++ of the basis.
  createRandomElement : (L M R, M R) -> M R
  ++ createRandomElement(aG,x) creates a random element of the group
  ++ algebra generated by aG.
  -- randomWord : (L L I, L M) -> M R
---+ You can create your own 'random' matrix with "randomWord(lli, lm)".
---+ Each li in lli determines a product of matrices, the entries in li
---+ determine which matrix from lm is chosen. Finally we sum over all
---+ products. The result "sm" can be used to call split with (e.g.)
---+ second parameter "first nullSpace sm"

if R has EuclideanDomain then -- using rowEchelon

\begin{verbatim}
cyclicSubmodule : (L M R, V R) -> V V R
  ++ cyclicSubmodule(lm,v) generates a basis as follows.
  ++ It is assumed that the size n of the vector equals the number
  ++ of rows and columns of the matrices. Then the matrices generate
  ++ a subalgebra, say \spad{A}, of the algebra of all square matrices of
  ++ dimension n. V R is an \spad{A}-module in the natural way.
  ++ cyclicSubmodule(lm,v) generates the R-Basis of Av as
  ++ described in section 6 of R. A. Parker's "The Meat-Axe".
  ++ Note that in contrast to the description in "The Meat-Axe" and to
  ++ standardBasisOfCyclicSubmodule the result is in echelon form.

standardBasisOfCyclicSubmodule : (L M R, V R) -> M R
  ++ standardBasisOfCyclicSubmodule(lm,v) returns a matrix as follows.
  ++ It is assumed that the size n of the vector equals the number
  ++ of rows and columns of the matrices. Then the matrices generate
  ++ a subalgebra, say \spad{A},
  ++ of the algebra of all square matrices of
  ++ dimension n. V R is an \spad{A}-module in the natural way.
  ++ standardBasisOfCyclicSubmodule(lm,v) calculates a matrix whose
  ++ non-zero column vectors are the R-Basis of Av achieved
  ++ in the way as described in section 6
  ++ of R. A. Parker's "The Meat-Axe".
  ++ Note that in contrast to cyclicSubmodule, the result is not
  ++ in echelon form.
\end{verbatim}

if R has Field then -- only because of inverse in SM

\begin{verbatim}
areEquivalent? : (L M R, L M R, B, I) -> M R
  ++ areEquivalent?(aG0,aG1,randomelements,numberOfTries) tests
  ++ whether the two lists of matrices, all assumed of same
  ++ square shape, can be simultaneously conjugated by a non-singular
  ++ matrix. If these matrices represent the same group generators,
  ++ the representations are equivalent.
  ++ The algorithm tries
  ++ numberOfTries times to create elements in the
  ++ generated algebras in the same fashion. If their ranks differ,
  ++ they are not equivalent. If an
  ++ isomorphism is assumed, then
  ++ the kernel of an element of the first algebra
  ++ is mapped to the kernel of the corresponding element in the
  ++ second algebra. Now consider the one-dimensional ones.
  ++ If they generate the whole space (e.g. irreducibility !)
  ++ we use standardBasisOfCyclicSubmodule to create the
  ++ only possible transition matrix. The method checks whether the
  ++ matrix conjugates all corresponding matrices from aG1.
  ++ The way to choose the singular matrices is as in meatAxe.
  ++ If the two representations are equivalent, this routine
\end{verbatim}
++ returns the transformation matrix TM with
++ aG0.i * TM = TM * aG1.i for all i. If the representations
++ are not equivalent, a small 0-matrix is returned.
++ Note that the case
++ with different sets of group generators cannot be handled.
areEquivalent? : (L M R, L M R) -> M R
++ areEquivalent?(aG0,aG1) calls areEquivalent?(aG0,aG1,true,25).
++ Note that the choice of 25 was rather arbitrary.
areEquivalent? : (L M R, L M R, I) -> M R
++ areEquivalent?(aG0,aG1,numberOfTries) calls
++ areEquivalent?(aG0,aG1,true,25).
++ Note that the choice of 25 was rather arbitrary.
isAbsolutelyIrreducible? : (L M R, I) -> B
++ isAbsolutelyIrreducible?(aG, numberOfTries) uses
++ Norton’s irreducibility test to check for absolute
++ irreducibility, assuming if a one-dimensional kernel is found.
++ As no field extension changes create "new" elements
++ in a one-dimensional space, the criterium stays true
++ for every extension. The method looks for one-dimensionals only
++ by creating random elements (no fingerprints) since
++ a run of meatAxe would have proved absolute irreducibility
++ anyway.
isAbsolutelyIrreducible? : L M R -> B
++ isAbsolutelyIrreducible?(aG) calls
++ isAbsolutelyIrreducible?(aG,25).
++ Note that the choice of 25 was rather arbitrary.
split : (L M R, V R) -> L L M R
++ split(aG, vector) returns a subalgebra \spad{A} of all
++ square matrix of dimension n as a list of list of matrices,
++ generated by the list of matrices aG, where n denotes both
++ the size of vector as well as the dimension of each of the
++ square matrices.
++ V R is an A-module in the natural way.
++ split(aG, vector) then checks whether the cyclic submodule
++ generated by vector is a proper submodule of V R.
++ If successful, it returns a two-element list, which contains
++ first the list of the representations of the submodule,
++ then the list of the representations of the factor module.
++ If the vector generates the whole module, a one-element list
++ of the old representation is given.
++ Note that a later version this should call the other split.
split: (L M R, V V R) -> L L M R
++ split(aG,submodule) uses a proper submodule of R**n
++ to create the representations of the submodule and of
++ the factor module.
if (R has Finite) and (R has Field) then
meatAxe : (L M R, B, I, I) -> L L M R
++ meatAxe(aG,randomElements,numberOfTries, maxTests) returns
++ a 2-list of representations as follows.
++ All matrices of argument aG are assumed to be square
meatAxe : L M R \rightarrow L L M R
++ meatAxe(aG) calls meatAxe(aG,\text{false},25,7) returns
++ a 2-list of representations as follows.
++ All matrices of argument \text{\spad{aG}} are assumed to be square
++ and of
++ equal size. Then \text{\spad{aG}} generates a subalgebra,
++ say \text{\spad{A}}, of the algebra
++ of all square matrices of dimension \(n\). \(V R\) is an \(A\)-module
++ in the usual way.
++ meatAxe(aG) creates at most 25 random elements
++ of the algebra, tests
++ them for singularity. If singular, it tries at most 7
++ elements of its kernel to generate a proper submodule.
++ If successful a list which contains first the list of the
++ representations of the submodule, then a list of the
++ representations of the factor module is returned.
++ Otherwise, if we know that all the kernel is already
++ scanned, Norton’s irreducibility test can be used either
++ to prove irreducibility or to find the splitting.
++ Notes: the first 6 tries use Parker’s fingerprints.
++ Also, 7 covers the case of three-dimensional kernels over the field with 2 elements.

meatAxe : (L M R, \text{B}) \rightarrow L L M R
++ meatAxe(aG, \text{randomElements}) calls meatAxe(aG,\text{false},6,7),
++ only using Parker’s fingerprints, if \text{randomElements} is false.
++ If it is true, it calls meatAxe(aG,\text{true},25,7),
++ only using random elements.
++ Note that the choice of 25 was rather arbitrary.
++ Also, 7 covers the case of three-dimensional kernels over the field
++ with 2 elements.

meatAxe : (L M R, \text{PI}) \rightarrow L L M R
++ meatAxe(aG, \text{numberOfTries}) calls
++ meatAxe(aG,\text{true},\text{numberOfTries},7).
++ Notes: 7 covers the case of three-dimensional
++ kernels over the field with 2 elements.
scanOneDimSubspaces: (L V R, I) -> V R
++ scanOneDimSubspaces(basis,n) gives a canonical representative
++ of the n-th one-dimensional subspace of the vector space
++ generated by the elements of basis, all from R**n.
++ The coefficients of the representative are of shape
++ (0,...,0,1,*...,*), * in R. If the size of R
++ is q, then there are (q**n-1)/(q-1) of them.
++ We first reduce n modulo this number, then find the
++ largest i such that +/[q**i for i in 0..i-1] <= n.
++ Subtracting this sum of powers from n results in an
++ i-digit number to basis q. This fills the positions of the
++ stars.

coerce

—— package RESLATC ResolveLatticeCompletion ——

)abbrev package RESLATC ResolveLatticeCompletion
++ Author: Stephen M. Watt
++ Date Created: 1986
++ Date Last Updated: May 30, 1991
++ Description:
++ This package provides coercions for the special types \spadtype{Exit}
++ and \spadtype{Void}.

ResolveLatticeCompletion(S: Type): with
   coerce: S -> Void
     + This coercion throws all information about s away.
     + This coercion allows values of any type to appear
     + in contexts where they will not be used.
     + For example, it allows the resolution of different types in
       + the \spad{then} and \spad{else} branches when an \spad{if}
       + is in a context where the resulting value is not used.
   coerce: Exit -> S
     + This coercion is
     + used for formal type correctness when a function will not
     + return directly to its caller.

== add
   coerce(s: S): Void == void()
   coerce(e: Exit): S ==

====================================================================
RootsFindingPackage examples
====================================================================

This package finds all the roots of a polynomial. If the constant field is not large enough then it returns the list of found zeros and the degree of the extension need to find the other roots missing. If the return degree is 1 then all the roots have been found. If 0 is return for the extension degree then there are an infinite number of zeros, that is you ask for the zeroes of 0. In the case of infinite field a list of all found zeros is kept and for each other call of a function that finds zeroes, a check is made on that list; this is to keep a kind of "canonical" representation of the elements.

SUP ==> SparseUnivariatePolynomial
REC ==> Record(zeros:List(K),extDegree:INT)

P== with

distinguishedRootsOf: (SUP(K),K) -> REC
++ distinguishedRootsOf returns a record consisting of a list of zeros
++ of the input polynomial followed by the smallest extension degree
++ needed to find all the zeros. If K has
++ \spad{PseudoAlgebraicClosureOfFiniteFieldCategory} or
++ \spad{PseudoAlgebraicClosureOfRationalNumberCategory} then
++ a root is created for each irreducible factor, and only these
++ roots are returns and not their conjugate.

distinguishedCommonRootsOf: (List SUP(K),K) -> REC
++ distinguishedCommonRootsOf returns the common zeros of a list of
++ polynomial. It returns a record as in distinguishedRootsOf. If 0
++ is returned as extension degree then there are an infinite number
++ of common zeros (in this case, the polynomial 0 was given in the
++ list of input polynomials).

foundZeroes: () -> List K
++ foundZeroes returns the list of already
++ found zeros by the functions
++ distinguishedRootsOf and
++ distinguishedCommonRootsOf.

setFoundZeroes: List K -> List K
++ setFoundZeroes sets the list of foundZeroes to the given one.

SquareFreeRegularSetDecompositionPackage.help

====================================================================
SquareFreeRegularSetDecompositionPackage examples
====================================================================

A package providing a new algorithm for solving polynomial systems by means of regular chains. Two ways of solving are provided: in the sense of Zariski closure (like in Kalkbrener's algorithm) or in the sense of the regular zeros (like in Wu, Wang or Lazard-Moreno methods). This algorithm is valid for any type of regular set. It does not care about the way a polynomial is added in an regular set, or how two quasi-components are compared (by an inclusion-test), or how the invertibility test is made in the tower of simple extensions associated with a regular set.

These operations are realized respectively by the domain TS and the packages QCMPPK(R,E,V,P,TS) and RSETGCD(R,E,V,P,TS).

The same way it does not care about the way univariate polynomial gcds (with coefficients in the tower of simple extensions associated with a regular set) are computed. The only requirement is that these gcds need to have invertible initials (normalized or not).

WARNING. There is no need for a user to call directly any operation of this package since they can be accessed by the domain \axiomType{TS}. 

Thus, the operations of this package are not documented.

CHAPTER 20. CHAPTER S

\abbrev package MATSTOR StorageEfficientMatrixOperations
++ Author: Clifton J. Williamson
++ Date Created: 18 July 1990
++ Date Last Updated: 18 July 1990
++ Description:
++ This package provides standard arithmetic operations on matrices.
++ The functions in this package store the results of computations
++ in existing matrices, rather than creating new matrices. This
++ package works only for matrices of type Matrix and uses the
++ internal representation of this type.

StorageEfficientMatrixOperations(R): Exports == Implementation where
R : Ring
M ==> Matrix R
NNI ==> NonNegativeInteger
ARR ==> PrimitiveArray R
REP ==> PrimitiveArray PrimitiveArray R

Exports ==> with
  copy_! : (M,M) -> M
    ++ \spad{copy!(c,a)} copies the matrix \spad{a} into the matrix c.
    ++ Error: if \spad{a} and c do not have the same
    ++ dimensions.
  plus_! : (M,M,M) -> M
    ++ \spad{plus!(c,a,b)} computes the matrix sum \spad{a + b} and stores the
    ++ result in the matrix c.
    ++ Error: if \spad{a}, b, and c do not have the same dimensions.
  minus_! : (M,M) -> M
    ++ \spad{minus!(c,a)} computes \spad{-a} and stores the result in the
    ++ matrix c.
    ++ Error: if a and c do not have the same dimensions.
  minus_! : (M,M,M) -> M
    ++ \spad{minus!(c,a,b)} computes the matrix difference \spad{a - b}
    ++ and stores the result in the matrix c.
    ++ Error: if \spad{a}, b, and c do not have the same dimensions.
  leftScalarTimes_! : (M,R,M) -> M
    ++ \spad{leftScalarTimes!(c,r,a)} computes \spad{r * a} and stores the result in the
    ++ matrix c.
    ++ Error: if \spad{a} and c do not have the same dimensions.
  rightScalarTimes_! : (M,M,R) -> M
    ++ \spad{rightScalarTimes!(c,a,r)} computes the scalar product
    ++ \spad{r * a} and stores the result in the matrix c.
    ++ Error: if \spad{a} and c do not have the same dimensions.
  times_! : (M,M,M) -> M
    ++ \spad{times!(c,a,b)} computes the matrix product \spad{a * b}
    ++ and stores the result in the matrix c.
    ++ Error: if \spad{a}, b, and c do not have
    ++ compatible dimensions.
  power_! : (M,M,M,NNI) -> M
    ++ \spad{power!(a,b,c,m,n)} computes \spad{m ** n} and stores the result in
++ \spad{a}. The matrices \spad{b} and \spad{c} are used to store intermediate results.
++ Error: if \spad{a}, \spad{b}, \spad{c}, and \spad{m} are not square
++ and of the same dimensions.

```spad
"**" : (M,NNI) -> M
++ \spad{\text{x ** n}} computes the n-th power
++ of a square matrix. The power \text{n} is assumed greater than 1.
```

Implementation ==> add

StreamTaylorSeriesOperations implements Taylor series arithmetic, where a Taylor series is represented by a stream of its coefficients.

Problems raising a UTS to a negative integer power.

The code in powern(rn,x) which raises an unnecessary error where no distinction between rational and integer powers are made.

The fix is easy. Since the problem does not exist in SUPS we can just take the definition there.

  ++ \spad{r*[a0,a1,...] = [r*a0,r*a1,...]}\n  "*" : (ST A,A) -> ST A
++ a * r returns the power series scalar multiplication of \spad{a} by r:
++ \spad{[a0,a1,...] * r = [a0 * r,a1 * r,...]}
"exquo" : (ST A,ST A) -> Union(ST A,"failed")
++ exquo(a,b) returns the power series quotient of \spad{a} by b,
++ if the quotient exists, and "failed" otherwise
"/"  : (ST A,ST A) -> ST A
++ a / b returns the power series quotient of \spad{a} by b.
++ An error message is returned if \spad{b} is not invertible.
++ This function is used in fixed point computations.
recip  : ST A -> UN
++ recip(a) returns the power series reciprocal of \spad{a}, or
++ "failed" if not possible.
monom  : (A,I) -> ST A
++ monom(deg,coef) is a monomial of degree deg with coefficient
++ coef.
integers  : I -> ST I
++ integers(n) returns \spad{[n,n+1,n+2,...]}.
oddintegers  : I -> ST I
++ oddintegers(n) returns \spad{[n,n+2,n+4,...]}.
int  : A -> ST A
++ int(r) returns \spad{[r,r+1,r+2,...]}, where r is a ring element.
mapmult  : (ST A,ST A) -> ST A
++ mapmult([a0,a1,..],[b0,b1,..])
++ returns \spad{[a0*b0,a1*b1,..]}.
deriv  : ST A -> ST A
++ deriv(a) returns the derivative of the power series with
++ respect to the power series variable. Thus
++ \spad{deriv([a0,a1,a2,...])} returns \spad{[a1,2 a2,3 a3,...]}.
gderiv  : (I -> A,ST A) -> ST A
++ gderiv(f,[a0,a1,a2,...]) returns
++ \spad{[f(0)*a0,f(1)*a1,f(2)*a2,..]}.
coerce  : A -> ST A
++ coerce(r) converts a ring element r to a stream with one element.
eval  : (ST A,A) -> ST A
++ eval(a,r) returns a stream of partial sums of the power series
++ \spad{a} evaluated at the power series variable equal to r.
compose  : (ST A,ST A) -> ST A
++ compose(a,b) composes the power series \spad{a} with
++ the power series b.
lagrange  : ST A -> ST A
++ lagrange(g) produces the power series for f where f is
++ implicitly defined as \spad{f(z) = z*g(f(z))}.
revert  : ST A -> ST A
++ revert(a) computes the inverse of a power series \spad{a}
++ with respect to composition.
++ the series should have constant coefficient 0 and first
++ order coefficient 1.
addiag  : ST ST A -> ST A
++ addiag(x) performs diagonal addition of a stream of streams. if x =
++ \spad{[[a<0,0>,a<0,1>,..],[a<1,0>,a<1,1>,..],[a<2,0>,a<2,1>,..],...]}
++ and \texttt{addiag(x)} = [b<0,b<1>,...], then b<k> = \sum(i+j=k,a<i,j>).

\texttt{lambert} : \texttt{ST A \rightarrow ST A}
++ \texttt{lambert(st)} computes \texttt{\{f(x) + f(x**2) + f(x**3) + \ldots\}}
++ if \texttt{st} is a stream representing \texttt{\{f(x)\}}.
++ This function is used for computing infinite products.
++ If \texttt{\{f(x)\}} is a power series with constant coefficient 1 then
++ \texttt{\prod(f(x**n),n = 1..infinity) = exp(lambert(log(f(x))))}.

\texttt{oddlambert} : \texttt{ST A \rightarrow ST A}

++ Description:
++ StructuralConstantsPackage provides functions creating
++ structural constants from a multiplication tables or a basis
++ of a matrix algebra and other useful functions in this context.

StructuralConstantsPackage(R:Field): public == private where

L ==> List
S ==> Symbol
FRAC ==> Fraction
POLY ==> Polynomial
V ==> Vector
M ==> Matrix
REC ==> Record(particular: Union(V R,"failed"),basis: List V R)
LSMP ==> LinearSystemMatrixPackage(R,V R,V R, M R)

public ==> with
   -- what we really want to have here is a matrix over
   -- linear polynomials in the list of symbols, having arbitrary
   -- coefficients from a ring extension of R, e.g. FRAC POLY R.
   structuralConstants : (L S, M FRAC POLY R) -> V M FRAC POLY R
   ++ structuralConstants(ls,mt) determines the structural constants
   ++ of an algebra with generators ls and multiplication table mt, the
   ++ entries of which must be given as linear polynomials in the
   ++ indeterminates given by ls. The result is in particular useful
   ++ as fourth argument for \spadtype{AlgebraGivenByStructuralConstants}
++ and \spadtype{GenericNonAssociativeAlgebra}.
structuralConstants : (L S, M POLY R) -> V M POLY R
++ structuralConstants(ls,mt) determines the structural constants
++ of an algebra with generators ls and multiplication table mt, the
++ entries of which must be given as linear polynomials in the
++ indeterminates given by ls. The result is in particular useful
++ as fourth argument for \spadtype{AlgebraGivenByStructuralConstants}
++ and \spadtype{GenericNonAssociativeAlgebra}.
structuralConstants: L M R -> V M R
++ structuralConstants(basis) takes the basis of a matrix
++ algebra, e.g. the result of \spadfun{basisOfCentroid} and calculates
++ the structural constants.
++ Note, that the it is not checked, whether basis really is a
++ basis of a matrix algebra.
coordinates: (M R, L M R) -> V R
++ coordinates(a,[v1,...,vn]) returns the coordinates of \spad{a}
++ with respect to the \spad{R}-module basis \spad{v1},...,\spad{vn}.

SystemSolvePackage examples

SystemSolvePackage examples

Symbolic solver for systems of rational functions with coefficients
in an integral domain R.

The systems are solved in the field of rational functions over R.
Solutions are exact of the form variable = value when the value is a
member of the coefficient domain R. Otherwise the solutions are
implicitly expressed as roots of univariate polynomial equations over R.

Care is taken to guarantee that the denominators of the input
equations do not vanish on the solution sets.

The arguments to solve can either be given as equations or as rational
functions interpreted as equal to zero. The user can specify an explicit list of symbols to be solved for, treating all other symbols appearing as parameters or omit the list of symbols in which case the system tries to solve with respect to all symbols appearing in the input.

++ Description:
++ Symbolic solver for systems of rational functions with coefficients in an integral domain R.
++ The systems are solved in the field of rational functions over R.
++ Solutions are exact of the form variable = value when the value is a member of the coefficient domain R. Otherwise the solutions are implicitly expressed as roots of univariate polynomial equations over R.
++ Care is taken to guarantee that the denominators of the input equations do not vanish on the solution sets.
++ The arguments to solve can either be given as equations or as rational functions interpreted as equal
++ to zero. The user can specify an explicit list of symbols to
++ be solved for, treating all other symbols appearing as parameters
++ or omit the list of symbols in which case the system tries to
++ solve with respect to all symbols appearing in the input.

SystemSolvePackage(R): Cat == Cap where

  NNI ==> NonNegativeInteger
  P ==> Polynomial
  EQ ==> Equation
  L ==> List
  V ==> Vector
  M ==> Matrix
  UP ==> SparseUnivariatePolynomial
  SE ==> Symbol
  IE ==> IndexedExponents Symbol
  SUP ==> SparseUnivariatePolynomial

  R : IntegralDomain
  F ==> Fraction Polynomial R
  PP2 ==> PolynomialFunctions2(R,F)
  PPR ==> Polynomial Polynomial R

Cat == with

  solve: (L F, L SE) -> L L EQ F
  ++ solve(lp,lv) finds the solutions of the list lp of
  ++ rational functions with respect to the list of symbols lv.

  solve: (L EQ F, L SE) -> L L EQ F
  ++ solve(le,lv) finds the solutions of the
  ++ list le of equations of rational functions
  ++ with respect to the list of symbols lv.

  solve: L F -> L L EQ F
  ++ solve(lp) finds the solutions of the list lp of rational
  ++ functions with respect to all symbols appearing in lp.

  solve: L EQ F -> L L EQ F
  ++ solve(le) finds the solutions of the list le of equations of
  ++ rational functions with respect to all symbols appearing in le.

  solve: (F, SE) -> L EQ F
  ++ solve(p,v) solves the equation p=0, where p is a rational function
  ++ with respect to the variable v.

  solve: (EQ F,SE) -> L EQ F
  ++ solve(eq,v) finds the solutions of the equation
  ++ eq with respect to the variable v.

  solve: F -> L EQ F
  ++ solve(p) finds the solution of a rational function p = 0
++ with respect to the unique variable appearing in p.

solve: EQ F -> L EQ F
++ solve(eq) finds the solutions of the equation eq
++ with respect to the unique variable appearing in eq.

triangularSystems: (L F, L SE) -> L L P R
++ triangularSystems(lf,lv) solves the system of equations
++ defined by lf with respect to the list of symbols lv;
++ the system of equations is obtaining
++ by equating to zero the list of rational functions lf.
++ The output is a list of solutions where
++ each solution is expressed as a "reduced" triangular system of
++ polynomials.

-- IS THERE A WORKING DOMAIN Tableau ?
-- coerce : M I -> Tableau(I)
-- ++ coerce(ytab) coerces the Young-Tableau ytab to an element of
-- ++ the domain Tableau(I).

coleman : (L I, L I, L I) -> M I
++ coleman(alpha,beta,pi):
++ there is a bijection from the set of matrices having nonnegative
++ entries and row sums alpha, column sums beta
++ to the set of Salpha - Sbeta double cosets of the
++ symmetric group Sn. (Salpha is the Young subgroup
++ corresponding to the improper partition alpha).
++ For a representing element pi of such a double coset,
++ coleman(alpha,beta,pi) generates the Coleman-matrix
++ corresponding to alpha, beta, pi.
++ Note that The permutation pi of \{1,2,\ldots,n\} has to be given
++ in list form.
++ Note that the inverse of this map is inverseColeman
++ (if pi is the lexicographical smallest permutation
++ in the coset). For details see James/Kerber.

inverseColeman : (L I, L I, M I) -> L I
++ inverseColeman(alpha,beta,C):
++ there is a bijection from the set of matrices having nonnegative
++ entries and row sums alpha, column sums beta
++ to the set of Salpha - Sbeta double cosets of the
++ symmetric group Sn. (Salpha is the Young subgroup
++ corresponding to the improper partition alpha).
++ For such a matrix C, inverseColeman(alpha,beta,C)
++ calculates the lexicographical smallest pi in the
++ corresponding double coset.
++ Note that the resulting permutation pi of \{1,2,\ldots,n\}
++ is given in list form.
++ Notes: the inverse of this map is coleman.
++ For details, see James/Kerber.

listYoungTableaus : (L I) -> L M I
++ listYoungTableaus(lambda) where lambda is a proper partition
++ generates the list of all standard tableaux of shape lambda
++ by means of lattice permutations. The numbers of the lattice
++ permutation are interpreted as column labels. Hence the
++ contents of these lattice permutations are the conjugate of
++ lambda.
++ Notes: the functions nextLatticePermutation and
++ makeYoungTableau are used.
++ The entries are from 0,...,n-1.
makeYoungTableau : (L I,L I) -> M I
  ++ makeYoungTableau(lambda,gitter) computes for a given lattice
  ++ permutation gitter and for an improper partition lambda
  ++ the corresponding standard tableau of shape lambda.
  ++ Notes: see listYoungTableaus.
  ++ The entries are from 0,...,n-1.
nextColeman : (L I, L I, M I) -> M I
  ++ nextColeman(alpha,beta,C) generates the next Coleman matrix
  ++ of column sums alpha and row sums beta according
  ++ to the lexicographical order from bottom-to-top.
  ++ The first Coleman matrix is achieved by C=new(1,1,0).
  ++ Also, new(1,1,0) indicates that C is the last Coleman matrix.
nextLatticePermutation : (L I, L I, B) -> L I
  ++ nextLatticePermutation(lambda,lattP,constructNotFirst) generates
  ++ the lattice permutation according to the proper partition
  ++ lambda succeeding the lattice permutation lattP in
  ++ lexicographical order as long as constructNotFirst is true.
  ++ If constructNotFirst is false, the first lattice permutation
  ++ is returned.
  ++ The result nil indicates that lattP has no successor.
nextPartition : (V I, V I, I) -> V I
  ++ nextPartition(gamma,part,number) generates the partition of
  ++ number which follows part according to the right-to-left
  ++ lexicographical order. The partition has the property that
  ++ its components do not exceed the corresponding components of
  ++ gamma. The first partition is achieved by part=[].
  ++ Also, [] indicates that part is the last partition.
nextPartition : (L I, V I, I) -> V I
  ++ nextPartition(gamma,part,number) generates the partition of
  ++ number which follows part according to the right-to-left
  ++ lexicographical order. The partition has the property that
  ++ its components do not exceed the corresponding components of
  ++ gamma. The first partition is achieved by part=[].
  ++ Also, [] indicates that part is the last partition.
numberOfImproperPartitions: (I,I) -> I
  ++ numberOfImproperPartitions(n,m) computes the number of partitions
  ++ of the nonnegative integer n in m nonnegative parts with regarding
  ++ the order (improper partitions).
  ++ Example: numberOfImproperPartitions (3,3) is 10,
  ++ since [0,0,3], [0,1,2], [0,2,1], [0,3,0], [1,0,2], [1,1,1],
  ++ [1,2,0], [2,0,1], [2,1,0], [3,0,0] are the possibilities.
  ++ Note that this operation has a recursive implementation.
subSet : (I,I,I) -> L I
  ++ subSet(n,m,k) calculates the k-th m-subset of the set
  ++ 0,1,...,(n-1) in the lexicographic order considered as
  ++ a decreasing map from 0,...,(m-1) into 0,...,(n-1).
  ++ See S.G. Williamson: Theorem 1.60.
  ++ Error: if not (0 <= m <= n and 0 <= k < (n choose m)).
unrankImproperPartitions0 : (I,I,I) -> L I
++ unrankImproperPartitions0(n,m,k) computes the k-th improper
++ partition of nonnegative n in m nonnegative parts in reverse
++ lexicographical order.
++ Example: [0,0,3] < [0,1,2] < [0,2,1] < [0,3,0] <
++ [1,0,2] < [1,1,1] < [1,2,0] < [2,0,1] < [2,1,0] < [3,0,0].
++ Error: if k is negative or too big.
++ Note that counting of subtrees is done by
++ numberOfImproperPartitions
unrankImproperPartitions1: (I,I,I) -> L I
++ unrankImproperPartitions1(n,m,k) computes the k-th improper
++ partition of nonnegative n in at most m nonnegative parts
++ ordered as follows: first, in reverse
++ lexicographically according to their non-zero parts, then
++ according to their positions (i.e. lexicographical order
++ using subSet: [3,0,0] < [0,3,0] < [0,0,3] < [2,1,0] <
++ [2,0,1] < [0,2,1] < [1,2,0] < [1,0,2] < [0,1,2] < [1,1,1].
++ Note that counting of subtrees is done by
++ numberOfImproperPartitionsInternal.

--- TaylorSolve.help ---

====================================================================
TaylorSolve examples
====================================================================

UTSSOL is a facility to compute the first few coefficients of a Taylor series given only implicitly by a function f that vanishes when applied to the Taylor series.

It uses the method of undetermined coefficients.

Could I either
take a function UTSCAT F $\rightarrow$ UTSCAT F and still be able to compute with undetermined coefficients, or
take a function F $\rightarrow$ F, and do likewise?

Let's see.

Try to compute the equation without resorting to power series. I.e., % c: SUP SUP F, and f: SUP SUP F $\rightarrow$ SUP SUP F. Won't this make the computation of coefficients terribly slow?

I could also try to replace transcendental kernels with variables\dots

Unfortunately, SUP F does not have TRANFUN -- well, it can't, of course. However, I'd like to be able to compute % sin(1+monomial(1,1)$UFPS SUP EXPR INT).

o )show TaylorSolve

---
TaylorSolve (UTSSOL)

Exports:
seriesSolve

--- package UTSSOL TaylorSolve ---

)abbrev package UTSSOL TaylorSolve
++ Description:
++ This package has no description

TaylorSolve(F, UTSF, UTSSUPF): Exports == Implementation where
  F: Field
  SUP ==> SparseUnivariatePolynomialExpressions
  UTSF: UnivariateTaylorSeriesCategory F
  UTSSUPF: UnivariateTaylorSeriesCategory SUP F
  NNI ==> NonNegativeInteger

Exports == with
  seriesSolve: (UTSSUPF -> UTSSUPF, List F) -> UTSF

Implementation == add
\getchunk{implementation: UTSSOL TaylorSolve}

--- implementation: UTSSOL TaylorSolve ---

seriesSolve(f, l) ==
c1 :=
  map((x:F):SUP F +-> x::(SUP F), l)
$ListFunctions2(F, SUP F)::(Stream SUP F)
coeffs: Stream SUP F := concat(c1, generate(monomial(1$F,1$NNI))))
-- coeffs: Stream SUP F := concat(c1, monomial(1$F,1$NNI))

coeffs is the stream of the already computed coefficients of the solution, plus one which is so far undetermined. We store in st.2 the complete stream and in st.1 the stream starting with the first coefficient that has possibly not yet been computed.

The mathematics is not quite worked out. If coeffs is initialized as stream with all coefficients set to the \emph{same} transcendental value, and not enough initial values are given, then the missing ones are implicitly assumed to be all identical. It may well happen that a solution is produced, although it is not uniquely determined dots

— implementation: UTSSOL TaylorSolve —

st: List Stream SUP F := [coeffs, coeffs]

Consider an arbitrary equation \( f(x, y(x)) = 0 \). When setting \( x = 0 \), we obtain \( f(0, y(0)) = 0 \). It is not necessarily the case that this determines \( y(0) \) uniquely, so we need one initial value that satisfies this equation.

\[ \text{seriesSolve} \text{ should check that the given initial values satisfy } f(0, y(0), y'(0), \ldots) = 0. \]

Now consider the derivatives of \( f \), where we write \( y \) instead of \( y(x) \) for better readability:

\[ \frac{d}{dx} f(x, y) = f_1(x, y) + f_2(x, y) y' \]

and

\[ \frac{d^2}{dx^2} f(x, y) = f_{1,1}(x, y) + f_{1,2}(x, y) y' + f_{2,1}(x, y) y'' + f_{2,2}(x, y) (y')^2 + f_2(x, y) y'''. \]

In general, \( \frac{d^2}{dx^2} f(x, y) \) depends only linearly on \( y'' \).

This points to another possibility: Since we know that we only need to solve linear equations, we could compute two values and then use interpolation. This might be a bit slower, but more importantly: can we still check that we have enough initial values? Furthermore, we then really need that \( f \) is analytic, i.e., operators are not necessarily allowed anymore. However, it seems that composition is allowed.
| implementation: UTSSOL TaylorSolve |

next: () -> F :=

   nr := st.1
   res: F

   if ground?(coeff: SUP F := nr.1)$(SUP F)

| |

If the next element was already calculated, we can simply return it:

| implementation: UTSSOL TaylorSolve |

   then
      res := ground coeff
      st.1 := rest nr
   else

| |

Otherwise, we have to find the first non-satisfied relation and solve it. It should be linear, or a single non-constant monomial. That is, the solution should be unique.

| implementation: UTSSOL TaylorSolve |

   ns := st.2
   eqs: Stream SUP F := coefficients f series ns
   while zero? first eqs repeat eqs := rest eqs
   eq: SUP F := first eqs
   if degree eq > 1 then
      if monomial? eq then res := 0
      else
         output(hconcat("The equation is: ", eq::OutputForm)) $OutputPackage
         error "seriesSolve: equation for coefficient not linear"
      else res := (-coefficient(eq, 0$NNI)$(SUP F)
               /coefficient(eq, 1$NNI)$(SUP F))

   nr.1 := res::SUP F
   --
   concat!(st.2, monomial(1$F,1$NNI))

--% Two Dimensional Function Plots

draw: (Ex,BIND,L DROP) -> VIEW2
  ++ draw(f(x),x = a..b,l) draws the graph of \spad{y = f(x)} as x
  ++ ranges from \spad{\min(a,b)} to \spad{\max(a,b)}; \spad{f(x)} is the
  ++ default title, and the options contained in the list l of
  ++ the domain \spad{DrawOption} are applied.
draw: (Ex,BIND) -> VIEW2
  ++ draw(f(x),x = a..b) draws the graph of \spad{y = f(x)} as x
  ++ ranges from \spad{\min(a,b)} to \spad{\max(a,b)}; \spad{f(x)} appears
  ++ in the title bar.

--% Parametric Plane Curves

draw: (PPC,BIND,L DROP) -> VIEW2
  ++ draw(curve(f(t),g(t)),t = a..b,l) draws the graph of the parametric
  ++ curve \spad{x = f(t), y = g(t)} as t ranges from \spad{\min(a,b)} to
  ++ \spad{\max(a,b)}; \spad{(f(t),g(t))} is the default title, and the
  ++ options contained in the list l of the domain \spad{DrawOption}
++ are applied.

draw: (PPC,BIND) -> VIEW2
++ draw(curve(f(t),g(t)),t = a..b) draws the graph of the parametric
++ curve \spad{x = f(t), y = g(t)} as \spad{t} ranges from \spad{\min(a,b)} to
++ \spad{\max(a,b)}; \spad{(f(t),g(t))} appears in the title bar.

--% Parametric Space Curves

draw: (PSC,BIND,L DROP) -> VIEW3
++ draw(curve(f(t),g(t),h(t)),t = a..b,l) draws the graph of the
++ parametric curve \spad{x = f(t)}, \spad{y = g(t)}, \spad{z = h(t)}
++ as \spad{t} ranges from \spad{\min(a,b)} to \spad{\max(a,b)}; \spad{h(t)}
++ is the default title, and the options contained in the list \spad{l} of
++ the domain \spadtype{DrawOption} are applied.
draw: (PSC,BIND) -> VIEW3
++ draw(curve(f(t),g(t),h(t)),t = a..b) draws the graph of the parametric
++ curve \spad{x = f(t)}, \spad{y = g(t)}, \spad{z = h(t)} as \spad{t} ranges
++ from \spad{\min(a,b)} to \spad{\max(a,b)}; \spad{h(t)} is the default
++ title.
makeObject: (PSC,BIND,L DROP) -> SPACE3
++ makeObject(curve(f(t),g(t),h(t)),t = a..b,l) returns a space of
++ the domain \spadtype{ThreeSpace} which contains the graph of the
++ parametric curve \spad{x = f(t)}, \spad{y = g(t)}, \spad{z = h(t)}
++ as \spad{t} ranges from \spad{\min(a,b)} to \spad{\max(a,b)}; \spad{h(t)}
++ is the default title, and the options contained in the list \spad{l} of
++ the domain \spadtype{DrawOption} are applied.
makeObject: (PSC,BIND) -> SPACE3
++ makeObject(curve(f(t),g(t),h(t)),t = a..b) returns a space of the
++ domain \spadtype{ThreeSpace} which contains the graph of the
++ parametric curve \spad{x = f(t)}, \spad{y = g(t)}, \spad{z = h(t)}
++ as \spad{t} ranges from \spad{\min(a,b)} to \spad{\max(a,b)}; \spad{h(t)} is
++ the default title.

--% Three Dimensional Function Plots

draw: (Ex,BIND,BIND,L DROP) -> VIEW3
++ draw(f(x,y),x = a..b,y = c..d,l) draws the graph of \spad{z = f(x,y)}
++ as \spad{x} ranges from \spad{\min(a,b)} to \spad{\max(a,b)} and \spad{y} ranges from
++ \spad{\min(c,d)} to \spad{\max(c,d)}; \spad{f(x,y)} is the default
++ title, and the options contained in the list \spad{l} of the domain
++ \spadtype{DrawOption} are applied.
draw: (Ex,BIND,BIND) -> VIEW3
++ draw(f(x,y),x = a..b,y = c..d) draws the graph of \spad{z = f(x,y)}
++ as \spad{x} ranges from \spad{\min(a,b)} to \spad{\max(a,b)} and \spad{y} ranges from
++ \spad{\min(c,d)} to \spad{\max(c,d)}; \spad{f(x,y)} appears in the title bar.
makeObject: (Ex,BIND,BIND,L DROP) -> SPACE3
++ makeObject(f(x,y),x = a..b,y = c..d,l) returns a space of the
++ domain \spadtype{ThreeSpace} which contains the graph of
++ \spad{z = f(x,y)} as \spad{x} ranges from \spad{\min(a,b)} to \spad{\max(a,b)}
++ and \spad{y} ranges from \spad{\min(c,d)} to \spad{\max(c,d)}; \spad{f(x,y)}
++ is the default title, and the options contained in the list 1 of the
++ domain \spad{DrawOption} are applied.
makeObject: (EX,BIND,BIND) -> SPACE3
++ makeObject(f(x,y),x = a..b,y = c..d) returns a space of the domain
++ \spadtype{ThreeSpace} which contains the graph of \spad{z = f(x,y)}
++ as x ranges from \spad{min(a,b)} to \spad{max(a,b)} and y ranges from
++ \spad{min(c,d)} to \spad{max(c,d)}; \spad{f(x,y)} appears as the
++ default title.

--% Parametric Surfaces

draw: (PSF,BIND,BIND,L DROP) -> VIEW3
++ draw(surface(f(u,v),g(u,v),h(u,v)),u = a..b,v = c..d,l) draws the
++ graph of the parametric surface \spad{x = f(u,v)}, \spad{y = g(u,v)},
++ \spad{z = h(u,v)} as u ranges from \spad{min(a,b)} to \spad{max(a,b)}
++ and v ranges from \spad{min(c,d)} to \spad{max(c,d)}; \spad{h(t)} is
++ the default title, and the options contained in the list 1 of
++ the domain \spad{DrawOption} are applied.
draw: (PSF,BIND,BIND) -> VIEW3
++ draw(surface(f(u,v),g(u,v),h(u,v)),u = a..b,v = c..d) draws the
++ graph of the parametric surface \spad{x = f(u,v)}, \spad{y = g(u,v)},
++ \spad{z = h(u,v)} as u ranges from \spad{min(a,b)} to \spad{max(a,b)}
++ and v ranges from \spad{min(c,d)} to \spad{max(c,d)}; \spad{h(t)} is
++ the default title.
makeObject: (PSF,BIND,BIND,L DROP) -> SPACE3
++ makeObject(surface(f(u,v),g(u,v),h(u,v)),u = a..b,v = c..d,l) returns
++ a space of the domain \spadtype{ThreeSpace} which contains the graph
++ of the parametric surface \spad{x = f(u,v)}, \spad{y = g(u,v)},
++ \spad{z = h(u,v)} as u ranges from \spad{min(a,b)} to \spad{max(a,b)}
++ and v ranges from \spad{min(c,d)} to \spad{max(c,d)}; \spad{h(t)} is
++ the default title, and the options contained in the list 1 of
++ the domain \spad{DrawOption} are applied.
makeObject: (PSF,BIND,BIND) -> SPACE3
++ makeObject(surface(f(u,v),g(u,v),h(u,v)),u = a..b,v = c..d) returns
++ a space of the domain \spadtype{ThreeSpace} which contains the
++ graph of the parametric surface \spad{x = f(u,v)}, \spad{y = g(u,v)},
++ \spad{z = h(u,v)} as u ranges from \spad{min(a,b)} to \spad{max(a,b)}
++ and v ranges from \spad{min(c,d)} to \spad{max(c,d)}; \spad{h(t)} is
++ the default title.

--% Two Dimensional Function Plots

draw: (SF -> SF,SEG,L DROP) -> VIEW2
   ++ draw(f,a..b,l) draws the graph of \spad{y = f(x)} as x
   ++ ranges from \spad{min(a,b)} to \spad{max(a,b)}.
   ++ The options contained in the list l of the
   ++ domain \spad{DrawOption} are applied.
draw: (SF -> SF,SEG) -> VIEW2
   ++ draw(f,a..b) draws the graph of \spad{y = f(x)} as x
   ++ ranges from \spad{min(a,b)} to \spad{max(a,b)}.

--% Parametric Plane Curves

draw: (PPC,SEG,L DROP) -> VIEW2
   ++ draw(curve(f,g),a..b,l) draws the graph of the parametric
   ++ curve \spad{x = f(t), y = g(t)} as t ranges from \spad{min(a,b)} to
   ++ \spad{max(a,b)}.
   ++ The options contained in the list l of the domain \spad{DrawOption}
   ++ are applied.
draw: (PPC,SEG) -> VIEW2
   ++ draw(curve(f,g),a..b) draws the graph of the parametric
   ++ curve \spad{x = f(t), y = g(t)} as t ranges from \spad{min(a,b)} to
   ++ \spad{max(a,b)}. 
--% Parametric Space Curves

\begin{verbatim}
draw: (PSC,SEG,L DROP) -> VIEW3
   ++ draw(curve(f,g,h),a..b,l) draws the graph of the parametric
   ++ curve \spad{x = f(t), y = g(t), z = h(t)} as t ranges from
   ++ \spad{\min(a,b)} to \spad{\max(a,b)}.
   ++ The options contained in the list l of the domain
   ++ \spad{DrawOption} are applied.
draw: (PSC,SEG) -> VIEW3
   ++ draw(curve(f,g,h),a..b,l) draws the graph of the parametric
   ++ curve \spad{x = f(t), y = g(t), z = h(t)} as t ranges from
   ++ \spad{\min(a,b)} to \spad{\max(a,b)}.
draw: (PCFUN,SEG,L DROP) -> VIEW3
   ++ draw(f,a..b,l) draws the graph of the parametric
   ++ curve \spad{f} as t ranges from
   ++ \spad{\min(a,b)} to \spad{\max(a,b)}.
   ++ The options contained in the list l of the domain
   ++ \spad{DrawOption} are applied.
draw: (PCFUN,SEG) -> VIEW3
   ++ draw(f,a..b,l) draws the graph of the parametric
   ++ curve \spad{f} as t ranges from
   ++ \spad{\min(a,b)} to \spad{\max(a,b)}.
makeObject: (PSC,SEG,L DROP) -> SPACE3
   ++ makeObject(curve(f,g,h),a..b,l) returns a space of the
   ++ domain \spad{ThreeSpace} which contains the graph of the
   ++ parametric curve \spad{x = f(t), y = g(t), z = h(t)} as t ranges from
   ++ \spad{\min(a,b)} to \spad{\max(a,b)}.
   ++ The options contained in the list l of the domain
   ++ \spad{DrawOption} are applied.
makeObject: (PSC,SEG) -> SPACE3
   ++ makeObject(sp,curve(f,g,h),a..b) returns the space \spad{sp}
   ++ of the domain \spad{ThreeSpace} with the addition of the graph
   ++ of the parametric curve \spad{x = f(t), y = g(t), z = h(t)} as t
   ++ ranges from \spad{\min(a,b)} to \spad{\max(a,b)}.
makeObject: (PCFUN,SEG,L DROP) -> SPACE3
   ++ makeObject(curve(f,g,h),a..b,l) returns a space of the
   ++ domain \spad{ThreeSpace} which contains the graph of the
   ++ parametric curve \spad{x = f(t), y = g(t), z = h(t)} as t ranges from
   ++ \spad{\min(a,b)} to \spad{\max(a,b)}.
   ++ The options contained in the list l of the domain
   ++ \spad{DrawOption} are applied.
makeObject: (PCFUN,SEG) -> SPACE3
   ++ makeObject(sp,curve(f,g,h),a..b) returns the space \spad{sp}
   ++ of the domain \spad{ThreeSpace} with the addition of the graph
   ++ of the parametric curve \spad{x = f(t), y = g(t), z = h(t)} as t
   ++ ranges from \spad{\min(a,b)} to \spad{\max(a,b)}.
\end{verbatim}

--% Three Dimensional Function Plots
draw: ((SF,SF) -> SF,SEG,SEG,L DROP) -> VIEW3
++ draw(f,a..b,c..d,l) draws the graph of \spad{z = f(x,y)}
++ as x ranges from \spad{\min(a,b)} to \spad{\max(a,b)} and y ranges from
++ \spad{\min(c,d)} to \spad{\max(c,d)}.
++ and the options contained in the list l of the domain
++ \spad{DrawOption} are applied.
draw: ((SF,SF) -> SF,SEG,SEG) -> VIEW3
++ draw(f,a..b,c..d) draws the graph of \spad{z = f(x,y)}

\texttt{recolor: ((SF,SF) \rightarrow Pt,(SF,SF,SF) \rightarrow SF) \rightarrow ((SF,SF) \rightarrow Pt)}
++ \texttt{recolor()}, uninteresting to top level user; exported in order to
++ compile package.

\textbf{Implementation} \Rightarrow \texttt{add}

I have had to work my way around the following bug in the compiler: When a local variable is given a mapping as a value, e.g.

\texttt{foo : SF \rightarrow SF := makeFloatFunction(f,t)},

the compiler cannot distinguish that local variable from a local function defined elsewhere in the package. Thus, when 'foo' is passed to a function, e.g.

\texttt{bird := fcn(foo)},

foo will often be compiled as DRAW;foo rather than foo. This, of course, causes a run-time error.

To avoid this problem, local variables are not given mappings as values, but rather (singleton) lists of mappings. The first element of the list can always be extracted and everything
goes through as before. There is no major loss in efficiency, as the computation of points will always dominate the computation time.

PRODUCT ==> Record(coef : Z, var : K)
FPR ==> Fraction Polynomial R

Exports ==> with
expand : F -> F
++ expand(f) performs the following expansions on f:
++ \item 1. logs of products are expanded into sums of logs,
++ \item 2. trigonometric and hyperbolic trigonometric functions
++ of sums are expanded into sums of products of trigonometric
++ and hyperbolic trigonometric functions.
++ \item 3. formal powers of the form \spad{(a/b)**c} are expanded into
++ \spad{a**c * b**(-c)}.
++ \end{items}
simplify : F -> F
++ simplify(f) performs the following simplifications on f:
++ \item 1. rewrites trigs and hyperbolic trigs in terms
++ of \spad{\sin}, \spad{\cos}, \spad{\sinh}, \spad{\cosh}.
++ \item 2. rewrites \spad{\sin**2} and \spad{\sinh**2} in terms
++ of \spad{\cos} and \spad{\cosh},
++ \item 3. rewrites \spad{\exp(a)*\exp(b)} as \spad{\exp(a+b)}.
++ \item 4. rewrites \spad{\exp((a**(1/n))**m * (a**(1/s))**t} as a single
++ power of a single radical of \spad{\exp(a)}.
++ \end{items}
htrigs : F -> F
++ htrigs(f) converts all the exponentials in f into
++ hyperbolic sines and cosines.
simplifyExp: F -> F
++ simplifyExp(f) converts every product \spad{\exp(a)*\exp(b)}
++ appearing in f into \spad{\exp(a+b)}.
simplifyLog : F -> F
++ simplifyLog(f) converts every \spad{\log(a) - \log(b)} appearing in f
++ into \spad{\log(a/b)}, every \spad{\log(a) + \log(b)} into \spad{\log(a*b)}
++ and every \spad{a*log(a)} into \spad{\log(a^n)}.
expandPower: F -> F
++ expandPower(f) converts every power \spad{(a/b)**c} appearing
++ in f into \spad{a**c * b**(-c)}.
expandLog : F -> F
++ expandLog(f) converts every \spad{\log(a/b)} appearing in f into
++ \spad{\log(a) - \log(b)}, and every \spad{\log(a*b)} into
++ \spad{\log(a) + \log(b)}..
cos2sec : F -> F
++ cos2sec(f) converts every \spad{cos(u)} appearing in f into
++ \spad{1/sec(u)}.
cosh2sech : F -> F
++ cosh2sech(f) converts every \spad{cosh(u)} appearing in f into
++ \spad{1/sech(u)}.
cot2trig : F -> F
++ cot2trig(f) converts every \spad{cot(u)} appearing in f into
++ \spad{cos(u)/sin(u)}.
coth2trigh : F -> F
++ coth2trigh(f) converts every \spad{coth(u)} appearing in f into
++ \spad{cosh(u)/sinh(u)}.
csc2sin : F -> F
++ csc2sin(f) converts every \spad{csc(u)} appearing in f into
++ \spad{1/sin(u)}.
csch2sinh : F -> F
++ csch2sinh(f) converts every \spad{csch(u)} appearing in f into
++ \spad{1/sinh(u)}.
sec2cos : F -> F
++ sec2cos(f) converts every \spad{sec(u)} appearing in f into
++ \spad{1/cos(u)}.
sech2cosh : F -> F
++ sech2cosh(f) converts every \spad{sech(u)} appearing in f into
++ \spad{1/cosh(u)}.
sin2csc : F -> F
++ sin2csc(f) converts every \spad{sin(u)} appearing in f into
++ \spad{1/csc(u)}.
sinh2csch : F -> F
++ sinh2csch(f) converts every \spad{sinh(u)} appearing in f into
++ \spad{1/csch(u)}.
tan2trig : F -> F
++ tan2trig(f) converts every \spad{tan(u)} appearing in f into
++ \spad{sin(u)/cos(u)}.
tanh2trigh : F -> F
++ tanh2trigh(f) converts every \spad{tanh(u)} appearing in f into
++ \spad{sinh(u)/cosh(u)}.
tan2cot : F -> F
++ tan2cot(f) converts every \spad{tan(u)} appearing in f into
++ \spad{1/cot(u)}.
tanh2coth : F -> F
++ tanh2coth(f) converts every \spad{tanh(u)} appearing in f into
++ \spad{1/coth(u)}.
cot2tan : F -> F
++ cot2tan(f) converts every \spad{cot(u)} appearing in f into
++ \spad{1/tan(u)}.
coth2tanh : F -> F
++ coth2tanh(f) converts every \spad{coth(u)} appearing in f into
++ \spad{1/tanh(u)}.
removeCosSq: F -> F
++ removeCosSq(f) converts every \spad{cos(u)**2} appearing in f into
++ \spad{1 - sin(x)**2}, and also reduces higher
++ powers of \spad{\cos(u)} with that formula.
removeSinSq: F -> F
++ removeSinSq(f) converts every \spad{\sin(u)**2} appearing in f into
++ \spad{1 - \cos(x)**2}, and also reduces higher powers of
++ \spad{\sin(u)} with that formula.
removeCoshSq:F -> F
++ removeCoshSq(f) converts every \spad{\cosh(u)**2} appearing in f into
++ \spad{1 - \sinh(x)**2}, and also reduces higher powers of
++ \spad{\cosh(u)} with that formula.
removeSinhSq:F -> F
++ removeSinhSq(f) converts every \spad{\sinh(u)**2} appearing in f into
++ \spad{1 - \cosh(x)**2}, and also reduces higher powers
++ of \spad{\sinh(u)} with that formula.
if R has PatternMatchable(R) and R has ConvertibleTo(Pattern(R))
and F has ConvertibleTo(Pattern(R)) and F has PatternMatchable R then
expandTrigProducts : F -> F
++ expandTrigProducts(e) replaces \spad{\sin(x)*\sin(y)} by
++ \spad{(\cos(x-y)-\cos(x+y))/2}, \spad{\cos(x)*\cos(y)} by
++ \spad{(\cos(x-y)+\cos(x+y))/2}, and \spad{\sin(x)*\cos(y)} by
++ \spad{(\sin(x-y)+\sin(x+y))/2}. Note that this operation uses
++ the pattern matcher and so is relatively expensive. To avoid
++ getting into an infinite loop the transformations are applied
++ at most ten times.

The htrigs function

The htrigs function can be used to replace and reduce hyperbolic trigonometric identities. The identity for \( \sinh(x) \) is \( (\exp(x) - \exp(-x))/2 \).

If we difference these we should get zero

\[
f := \sinh(x) - \frac{\exp(x) - \exp(-x)}{2}
\]

instead, by default, we get

\[
\frac{x - x}{2 \sinh(x) - e^x + e^{-x}}
\]

The function htrigs(\( f \)) gives 0.

This works as follows:

\[
m := \text{mainKernel } f \Rightarrow \sinh(x)
\]

which is coerced to the first part of the union:

\[
k := m::\text{Kernel(Expression(Integer))}
\]

and the operator is extracted:

\[
\text{op} := \text{operator(k)} \Rightarrow \sinh
\]

The argument function extracts the variable used as arguments:

\[
\text{argument k} \Rightarrow [x]
\]

At this point we have picked apart the main Kernel into its operator and its arguments. We now process the list of arguments.

The function htrigs is called on every element of the argument list, which in this case, returns a list:

\[
\text{arg} := [\text{htrigs } x \text{ for } x \text{ in } \text{argument } k]\$\text{List(Expression(Integer))} \\
=> [x]
\]

Type: List(Expression(Integer))
We form a polynomial by replacing the kernel in the numerator with ?

\[
\text{num} := \text{univariate(numer f, k)}
\]

\[
2x - e^{-x} + e^x
\]

Type: \(\text{SparseUnivariatePolynomial}\)

\(\text{SparseMultivariatePolynomial}\)

\(\text{Integer}, \text{Kernel(Expression(Integer)))}\)

and a polynomial of the denominator, replacing the kernel

\[
\text{den} := \text{univariate(denom f, k)}
\]

\[
2
\]

Type: \(\text{SparseUnivariatePolynomial}\)

\(\text{SparseMultivariatePolynomial}\)

\(\text{Integer}, \text{Kernel(Expression(Integer)))}\)

In this case the op is not the exponential so we are doing straight trig substitution. We reconstruct the function call using the op and arg values, that is:

\[
\text{g1} := \text{op arg} \Rightarrow \sinh(x)
\]

Type: \(\text{Expression(Integer)}\)

So sup2htrigs, which is a local function, is used to simplify the parts of the fraction. In this case,

\[
\text{sup2htrigs(num, g1 := op arg) \Rightarrow 0}
\]

Type: \(\text{Expression(Integer)}\)

\[
\text{sup2htrigs(den, g1) \Rightarrow 2}
\]

Type: \(\text{Expression(Integer)}\)

Thus, the result is 0

The identity for \(\cosh(x)\) is \((e^x + e^{-x})/2\)

If we difference these we should get zero

\[
f := \cosh(x) - (e^x + e^{-x})/2
\]

instead, by default, we get

\[
x - e^{-x} + e^x + 2\cosh(x)
\]

\[
------------------------
2
\]

and the function call \(htrigs(f)\) gives 0

This works as follows:
which is coerced to the first part of the union:

\[
x
\]

\[
k:=m::\text{Kernel(Expression(Integer))} => \%e
\]

and the operator is extracted:

\[
op:=\text{operator}(k) => \exp
\]

The argument function extracts the variable used as arguments:

\[
\text{argument } k ==> [x]
\]

At this point we have picked apart the main Kernel into its operator and its arguments. We now process the list of arguments.

The \text{htrigs} function is called on every element of the argument list, which in this case, returns a list:

\[
\text{arg}:=\{\text{htrigs } x \text{ for } x \text{ in argument } k\}\]$List(Expression(Integer))

We form polynomial by replacing the kernel in the numerator with ?

\[
\text{num} := \text{univariate(numer } f, k)
\]

\[
- x
- ? - \%e + 2\cosh(x)
\]

and a polynomial of the denominator, replacing the kernel

\[
\text{den} := \text{univariate(denom } f, k)
\]

\[
2
\]
In this case, the expression

\[ \text{is?(op, "exp":Symbol) => true} \]

so we form

\[ a := \text{first arg => x} \]
\[ \text{Type: Expression(Integer)} \]

since we know that

\[ \cosh(x)+\sinh(x) => \%e \]

we can form this use this expression in substitutions

\[ g1 := \cosh(a)+\sinh(a) => \sinh(x)+\cosh(x) \]
\[ \text{Type: Expression(Integer)} \]

since we know that

\[ -x \]
\[ \cosh(x)-\sinh(x) => -\%e \]

we can form this use this expression in substitutions

\[ g2 := \cosh(a)-\sinh(a) => -\sinh(x)+\cosh(x) \]
\[ \text{Type: Expression(Integer)} \]

\[ b := (\text{degree num}):Integer \text{ quo 2} => 0 \]
\[ \text{Type: NonNegativeInteger} \]

The supexp function is using the \( g1 \) and \( g2 \) identities to replace \( \exp(x) \)

\[ \text{supexp(num,g1,g2,b)} => \sinh(x)-\cosh(x)-\sinh(x)+2\cosh(x)-\cosh(x) \]
\[ \text{Type: Expression(Integer)} \]

\[ \text{supexp(den,g1,g2,b)} => 2 \]
\[ \text{Type: Expression(Integer)} \]

which is effectively

\[ \frac{t1}{t2} => \frac{(\sinh(x)-\cosh(x)-\sinh(x)+2\cosh(x)-\cosh(x))}{2} \]
\[ \text{Type: Expression(Integer)} \]

the last form of which can be rearranged as:

\[ \frac{(\sinh(x)-\sinh(x) + 2\cosh(x)-\cosh(x)-\cosh(x))}{2} => 0 \]
so the result is 0

--E 4
This package tries to find solutions of equations of type Expression(R).

This means expressions involving transcendental, exponential, logarithmic
and nthRoot functions.

After trying to transform different kernels to one kernel by applying
several rules, it calls zerosOf for the SparseUnivariatePolynomial in
the remaining kernel.

For example the expression
\[ \sin(x) \cdot \cos(x) - 2 \]
will be transformed to
\[ -2 \tan(x/2)**4 - 2 \tan(x/2)**3 - 4 \tan(x/2)**2 + 2 \tan(x/2) - 2 \]
by using the function normalize and then to
\[ -2 \tan(x)**2 + \tan(x) - 2 \]
with help of subsTan. This function tries to express the given function
in terms of tan(x/2) to express in terms of tan(x).

Other examples are the expressions
\[ \sqrt{x+1} + \sqrt{x+7} + 1 \]
\[ \sqrt{\sin(x)} + 1 \]
\[ \text{solve}\left(\frac{1}{2}v^2\cos(\theta+\phi)\cos(\theta+\phi)+g*1\cos(\phi)=g*1,\phi\right) \]

++ Date Created: Summer 1991
++ Date Last Changed: 9/91
++ Description:
++ This package tries to find solutions of equations of type Expression(R).
++ This means expressions involving transcendental, exponential, logarithmic
++ and n-thRoot functions.
++ After trying to transform different kernels to one kernel by applying
++ several rules, it calls zerosOf for the SparseUnivariatePolynomial in
++ the remaining kernel.
++ For example the expression \(\sin(x)\cdot\cos(x) - 2\) will be transformed to
++ \(-2\tan(x/2)^4 - 2\tan(x/2)^3 - 4\tan(x/2)^2 + 2\tan(x/2) - 2\)
++ by using the function normalize and then to
++ \(-2\tan(x)^2 + \tan(x) - 2\)
++ with help of subsTan. This function tries to express the given function
++ in terms of \(\tan(x/2)\) to express in terms of \(\tan(x)\).
++ Other examples are the expressions \(\sqrt{x+1} + \sqrt{x+7} + 1\) or
++ \(\sqrt{\sin(x)} + 1\).

This package finds the function func3 where func1 and func2 are given and func1 = func3(func2). If there is no solution then function func1 will be returned.

An example would be

\[
\text{func1} := 8\times X^3 + 32\times X^2 - 14\times X \quad \text{::EXPR INT}
\]

and

\[
\text{func2} := 2\times X \quad \text{::EXPR INT}
\]

convert them via univariate to FRAC SUP EXPR INT and then the solution is

\[
\text{func3} := X^3 + X^2 - X
\]

of type FRAC SUP EXPR INT

---
This package provides functions that compute "fraction-free" inverses of upper and lower triangular matrices over a integral domain. By "fraction-free inverses" we mean the following: given a matrix $B$ with entries in $R$ and an element $d$ of $R$ such that $d \cdot \text{inv}(B)$ also has entries in $R$, we return $d \cdot \text{inv}(B)$. Thus, it is not necessary to pass to the quotient field in any of our computations.

See Also:

++ Author: Clifton J. Williamson
++ Date Created: Bastille Day 1989
++ Date Last Updated: 5 June 1990
++ Description:
++ Tools for constructing tubes around 3-dimensional parametric curves.

TubePlotTools(): Exports == Implementation where
  I ==> Integer
  SF ==> DoubleFloat
  L ==> List
  Pt ==> Point SF

Exports ==> with
  point: (SF,SF,SF,SF) -> Pt
  ++ point(x1,x2,x3,c) creates and returns a point from the three
  ++ specified coordinates \spad{x1}, \spad{x2}, \spad{x3}, and also
  ++ a fourth coordinate, c, which is generally used to specify the
  ++ color of the point.
  "*" : (SF,Pt) -> Pt
  ++ s * p returns a point whose coordinates are the scalar multiple
  ++ of the point p by the scalar s, preserving the color, or fourth
  ++ coordinate, of p.
  "+" : (Pt,Pt) -> Pt
  ++ p + q computes and returns a point whose coordinates are the sums
  ++ of the coordinates of the two points \spad{p} and \spad{q}, using
  ++ the color, or fourth coordinate, of the first point \spad{p}
  ++ as the color also of the point \spad{q}.
  "-" : (Pt,Pt) -> Pt
CHAPTER 21. CHAPTER T

++ $p - q$ computes and returns a point whose coordinates are the
++ differences of the coordinates of two points \spad{p} and \spad{q},
++ using the color, or fourth coordinate, of the first point \spad{p}
++ as the color also of the point \spad{q}.

dot : (Pt,Pt) -> SF
++ \{dot(p,q)\} computes the dot product of the two points \spad{p}
++ and \spad{q} using only the first three coordinates, and returns
++ the resulting \spadtype{DoubleFloat}.

cross : (Pt,Pt) -> Pt
++ \{cross(p,q)\} computes the cross product of the two points \spad{p}
++ and \spad{q} using only the first three coordinates, and keeping
++ the color of the first point \spad{p}. The result is returned as a point.

unitVector: Pt -> Pt
++ \{unitVector(p)\} creates the unit vector of the point \spad{p} and returns
++ the result as a point. Note that \spad{unitVector(p) = p/|p|}.

cosSinInfo: I -> L L SF
++ \{cosSinInfo(n)\} returns the list of lists of values for \spad{n}, in the form
++ \{\spad{[[cos(n-1) a,sin(n-1) a],...,[cos 2 a,sin 2 a],[cos a,sin a]]}\}
++ where \spad{a = 2 pi/n}. Note that \spad{n} should be greater than 2.

loopPoints: (Pt,Pt,Pt,SF,L L SF) -> L Pt
++ \{loopPoints(p,n,b,r,lls)\} creates and returns a list of points
++ which form the loop with radius \spad{r}, around the center point
++ indicated by the point \spad{p}, with the principal normal vector of
++ the space curve at point \spad{p} given by the point\{vector\} \spad{n}, and the
++ binormal vector given by the point\{vector\} \spad{b}, and a list of lists,
++ \spad{lls}, which is the \spadfun{cosSinInfo} of the number of points
++ defining the loop.

package UPSQFREE UnivariatePolynomialSquareFree

)abbrev package UPSQFREE UnivariatePolynomialSquareFree
++ Author: Dave Barton, Barry Trager
++ Description:
++ This package provides for square-free decomposition of
++ univariate polynomials over arbitrary rings, i.e.
++ a partial factorization such that each factor is a product
++ of irreducibles with multiplicity one and the factors are
++ pairwise relatively prime. If the ring
++ has characteristic zero, the result is guaranteed to satisfy
++ this condition. If the ring is an infinite ring of
++ finite characteristic, then it may not be possible to decide when
++ polynomials contain factors which are pth powers. In this
++ case, the flag associated with that polynomial is set to "nil"
++ (meaning that that polynomials are not guaranteed to be square-free).

UnivariatePolynomialSquareFree(RC:IntegralDomain,P):C == T

where
fUnion ==> Union("nil", "sqfr", "irred", "prime")
FF ==> Record(flg:fUnion, fctr:P, xpnt:Integer)
P:Join(UnivariatePolynomialCategory(RC),IntegralDomain) with
  gcd: (%,%) -> %
  ++ gcd(p,q) computes the greatest-common-divisor of p and q.
C == with
  squareFree: P -> Factored(P)
  ++ squareFree(p) computes the square-free factorization of the
  ++ univariate polynomial p. Each factor has no repeated roots, and the
  ++ factors are pairwise relatively prime.
  squareFreePart: P -> P
  ++ squareFreePart(p) returns a polynomial which has the same
  ++ irreducible factors as the univariate polynomial p, but each
  ++ factor has multiplicity one.
  BumInSepFFE: FF -> FF
  ++ BumInSepFFE(f) is a local function, exported only because
  ++ it has multiple conditional definitions.

VectorFunctions2 examples

This package provides operations which all take as arguments vectors of elements of some type \texttt{A} and functions from \texttt{A} to another of type \texttt{B}. The operations all iterate over their vector argument and either return a value of type \texttt{B} or a vector over \texttt{B}.

See Also:
o \texttt{)show VectorFunctions2}

Export:
map, reduce, scan

\begin{verbatim}
)abbrev package VECTOR2 VectorFunctions2
++ Description:
++ This package provides operations which all take as arguments
++ vectors of elements of some type \texttt{A} and functions from \texttt{A} to
++ another of type \texttt{B}. The operations all iterate over their vector argument
++ and either return a value of type \texttt{B} or a vector over \texttt{B}.

VectorFunctions2(A, B): Exports == Implementation where
A, B: Type
\end{verbatim}
VA ==> Vector A
VB ==> Vector B
O2 ==> FiniteLinearAggregateFunctions2(A, VA, B, VB)
UB ==> Union(B, "failed")

Exports ==> with
   scan ((A, B) -> B, VA, B) -> VB
   ++ scan(func, vec, ident) creates a new vector whose elements are
   ++ the result of applying reduce to the binary function func,
   ++ increasing initial subsequences of the vector vec,
   ++ and the element ident.
   reduce ((A, B) -> B, VA, B) -> B
   ++ reduce(func, vec, ident) combines the elements in vec using the
   ++ binary function func. Argument ident is returned if vec is empty.
   map : (A -> B, VA) -> VB
   ++ map(f, v) applies the function f to every element of the vector v
   ++ producing a new vector containing the values.
   map : (A -> UB, VA) -> Union(VB, "failed")
   ++ map(f, v) applies the function f to every element of the vector v
   ++ producing a new vector containing the values or \spad{"failed"}.

Implementation ==> add

  axesColorDefault : PAL -> PAL
  ++ axesColorDefault(p) sets the default color of the axes in a 2D
  ++ viewport to the palette p.

  unitsColorDefault : () -> PAL
  ++ unitsColorDefault() returns the default color of the unit ticks in
  ++ a 2D viewport.

  unitsColorDefault : PAL -> PAL
++ unitsColorDefault(p) sets the default color of the unit ticks in
++ a 2D viewport to the palette p.

pointSizeDefault : () -> PI
++ pointSizeDefault() returns the default size of the points in
++ a 2D viewport.

pointSizeDefault : PI -> PI
++ pointSizeDefault(i) sets the default size of the points in a 2D
++ viewport to i.

viewPosDefault : () -> L NNI
++ viewPosDefault() returns the default x and y position of a
++ viewport window unless overridden explicitly, newly created
++ viewports will have this x and y coordinate.

viewPosDefault : L NNI -> L NNI
++ viewPosDefault([x,y]) sets the default x and y position of a
++ viewport window unless overridden explicitly, newly created
++ viewports will have the x and y coordinates x, y.

viewSizeDefault : () -> L PI
++ viewSizeDefault() returns the default viewport width and height.

viewSizeDefault : L PI -> L PI
++ viewSizeDefault([w,h]) sets the default viewport width to w and height
++ to h.

viewDefaults : () -> Void
++ viewDefaults() resets all the default graphics settings.

viewWriteDefault : () -> L S
++ viewWriteDefault() returns the list of things to write in a viewport
++ data file; a viewalone file is always generated.

viewWriteDefault : L S -> L S
++ viewWriteDefault(l) sets the default list of things to write in a
++ viewport data file to the strings in l; a viewalone file is always
++ generated.

viewWriteAvailable : () -> L S
++ viewWriteAvailable() returns a list of available methods for writing,
++ such as BITMAP, POSTSCRIPT, etc.

var1StepsDefault : () -> PI
++ var1StepsDefault() is the current setting for the number of steps to
++ take when creating a 3D mesh in the direction of the first defined
++ free variable (a free variable is considered defined when its
++ range is specified (e.g. x=0..10)).
var2StepsDefault : () -> PI
++ var2StepsDefault() is the current setting for the number of steps to
++ take when creating a 3D mesh in the direction of the first defined
++ free variable (a free variable is considered defined when its
++ range is specified (e.g. x=0..10)).

var1StepsDefault : PI -> PI
++ var1StepsDefault(i) sets the number of steps to take when creating a
++ 3D mesh in the direction of the first defined free variable to i
++ (a free variable is considered defined when its range is specified
++ (e.g. x=0..10)).

var2StepsDefault : PI -> PI
++ var2StepsDefault(i) sets the number of steps to take when creating a
++ 3D mesh in the direction of the first defined free variable to i
++ (a free variable is considered defined when its range is specified
++ (e.g. x=0..10)).

tubePointsDefault : PI -> PI
++ tubePointsDefault(i) sets the number of points to use when creating
++ the circle to be used in creating a 3D tube plot to i.

tubePointsDefault : () -> PI
++ tubePointsDefault() returns the number of points to be used when
++ creating the circle to be used in creating a 3D tube plot.

tubeRadiusDefault : Float -> SF -- current tube.spad asks for SF
++ tubeRadiusDefault(r) sets the default radius for a 3D tube plot to r.

tubeRadiusDefault : () -> SF
++ tubeRadiusDefault() returns the radius used for a 3D tube plot.

++ Author: Jim Wen
++ Date Created: 30 April 1989
++ Date Last Updated: 15 June 1990
++ Description:
++ ViewportPackage provides functions for creating GraphImages
++ and TwoDimensionalViewports from lists of lists of points.

ViewportPackage():Exports == Implementation where
DROP ==> DrawOption
GRIMAGE ==> GraphImage
L ==> List
P ==> Point DoubleFloat
PAL ==> Palette
PI ==> PositiveInteger
VIEW2D ==> TwoDimensionalViewport
Exports == with

  graphCurves : (L L P,PAL,PAL,PI,L DROP) -> GRIMAGE
  ++ graphCurves([p0],[p1],...,[pn],ptColor,lineColor,ptSize,[options])
  ++ creates a \spadtype{GraphImage} from the list of lists of points, p0
  ++ through pn, using the options specified in the list \spad{options}.
  ++ The graph point color is specified by \spad{ptColor}, the graph line
  ++ color is specified by \spad{lineColor}, and the size of the points is
  ++ specified by \spad{ptSize}.

  graphCurves : (L L P,L DROP) -> GRIMAGE
  ++ graphCurves([p0],[p1],...,[pn]) creates a \spadtype{GraphImage} from
  ++ the list of lists of points indicated by p0 through pn.

  graphCurves : (L L P,L DROP) -> GRIMAGE
++ graphCurves([[p0],[p1],...,[pn]], [options]) creates a
++ \spadtype{GraphImage} from the list of lists of points, p0 through pn,
++ using the options specified in the list \spad{options}.

drawCurves : (L L P, PAL, PAL, PI, L DROP) -> VIEW2D
++ drawCurves([[p0],[p1],...,[pn]], ptColor, lineColor, ptSize, [options])
++ creates a \spadtype{TwoDimensionalViewport} from the list of lists of
++ points, p0 through pn, using the options specified in the list
++ \spad{options}. The point color is specified by \spad{ptColor}, the
++ line color is specified by \spad{lineColor}, and the point size is
++ specified by \spad{ptSize}.

drawCurves : (L L P, L DROP) -> VIEW2D
++ drawCurves([[p0],[p1],...,[pn]], [options]) creates a
++ \spadtype{TwoDimensionalViewport} from the list of lists of points,
++ p0 through pn, using the options specified in the list \spad{options};

coerce : GRIMAGE -> VIEW2D
++ coerce(gi) converts the indicated \spadtype{GraphImage}, gi, into the
++ \spadtype{TwoDimensionalViewport} form.

Chapter Y
package ZDSOLVE ZeroDimensionalSolvePackage

Based on triangular decompositions and the RealClosure constructor, the package ZeroDimensionalSolvePackage provides operations for computing symbolically the real or complex roots of polynomial systems with finitely many solutions.

)spool

)lisp (bye)
A package for computing symbolically the complex and real roots of zero-dimensional algebraic systems over the integer or rational numbers. Complex roots are given by means of univariate representations of irreducible regular chains. Real roots are given by means of tuples of coordinates lying in the RealClosure of the coefficient ring.

This constructor takes three arguments. The first one $R$ is the coefficient ring. The second one $\text{ls}$ is the list of variables involved in the systems to solve. The third one must be $\text{concat}(\text{ls}, s)$ where $s$ is an additional symbol used for the univariate representations.

WARNING. The third argument is not checked.

All operations are based on triangular decompositions. The default is to compute these decompositions directly from the input system by using the RegularChain domain constructor.

The lexTriangular algorithm can also be used for computing these decompositions (see LexTriangularPackage package constructor).

For that purpose, the operations univariateSolve, realSolve and positiveSolve admit an optional argument.

The ZeroDimensionalSolvePackage package constructor provides operations for computing symbolically the complex or real roots of zero-dimensional algebraic systems.

The package provides no multiplicity information (i.e. some returned roots may be double or higher) but only distinct roots are returned.

Complex roots are given by means of univariate representations of irreducible regular chains. These representations are computed by the univariateSolve operation (by calling the InternalRationalUnivariateRepresentationPackage package constructor which does the job).

Real roots are given by means of tuples of coordinates lying in the RealClosure of the coefficient ring. They are computed by the realSolve and positiveSolve operations. The former computes all the solutions of the input system with real coordinates whereas the later concentrate on the solutions with (strictly) positive coordinates. In
both cases, the computations are performed by the RealClosure constructor.

Both computations of complex roots and real roots rely on triangular decompositions. These decompositions can be computed in two different ways. First, by applying the zeroSetSplit operation from the REGSET domain constructor. In that case, no Groebner bases are computed. This strategy is used by default. Secondly, by applying the zeroSetSplit from LEXTRIPK. To use this later strategy with the operations univariateSolve, realSolve and positiveSolve one just needs to use an extra boolean argument.

Note that the way of understanding triangular decompositions is detailed in the example of the RegularTriangularSet constructor.

The ZeroDimensionalSolvePackage constructor takes three arguments. The first one R is the coefficient ring; it must belong to the categories OrderedRing, EuclideanDomain, CharacteristicZero and RealConstant. This means essentially that R is Integer or Fraction(Integer). The second argument ls is the list of variables involved in the systems to solve. The third one MUST BE concat(ls,s) where s is an additional symbol used for the univariate representations. The abbreviation for ZeroDimensionalSolvePackage is ZDSOLVE.

We illustrate now how to use the constructor ZDSOLVE by two examples: the Arnborg and Lazard system and the L-3 system (Aubry and Moreno Maza). Note that the use of this package is also demonstrated in the example of the LexTriangularPackage constructor.

Define the coefficient ring.

```
R := Integer
       Integer
       Type: Domain
```

Define the lists of variables:

```
ls : List Symbol := [x,y,z,t]
    [x,y,z,t]
    Type: List Symbol
```

and:

```
ls2 : List Symbol := [x,y,z,t,new()$Symbol]
    [x,y,z,t,%A]
    Type: List Symbol
```

Call the package:

```
pack := ZDSOLVE(R,ls,ls2)
       ZeroDimensionalSolvePackage(Integer,[x,y,z,t],[x,y,z,t,%A])
```
CHAPTER 27. CHAPTER Z

Type: Domain

Define a polynomial system (Arnborg-Lazard)

\[ p_1 := x^{2}y^{2}z + x^{2}y^{2}z^2 + x^{2}y^{2}z + x^{2}y^2 + x^{2}y + x^2 + yz + y^2 + x + y \]
\[ Type: Polynomial Integer \]

\[ p_2 := x^{2}y^{2}z^2 + x^{2}y^{2}z^2 + x^{2}y^{2}z + x^{2}y^2 + yz + x + z \]
\[ Type: Polynomial Integer \]

\[ p_3 := x^{2}y^{2}z^2 + x^{2}y^{2}z^2 + x^{2}y^{2}z + x^{2}y^2 + xz + z + 1 \]
\[ Type: Polynomial Integer \]

\[ lp := [p_1, p_2, p_3] \]
\[ Type: List Polynomial Integer \]

Note that these polynomials do not involve the variable t; we will use it in the second example.

First compute a decomposition into regular chains (i.e. regular triangular sets).

\[ \text{triangSolve}(lp) \]
\[ \{ \]
\[ 20 19 18 17 16 15 14 13 12 \]
\[ z - 6z - 41z + 71z + 106z + 92z + 197z + 145z + 257z + \]
\[ 11 10 9 8 7 6 5 4 3 \]
\[ 278z + 201z + 145z + 197z + 92z + 106z + 71z + \]
\[ 2 \]
\[ - 41z - 6z + 1 \]
\[ 14745844z + 50357474z - 130948867z - 185261586z + \]
\[ 15 14 13 12 \]

CHAPTER 27. CHAPTER Z
We can see easily from this decomposition (consisting of a single regular chain) that the input system has 20 complex roots.

Then we compute a univariate representation of this regular chain.

```
univariateSolve(lp)$pack
[
  complexRoots =
    12 11 10 9 8 7 6 5 4 3
    +
    2
    24?  - 12?  + 1
  ,
  coordinates =
    11 10 9 8 7 6
    63x  + 62%A  - 721%A  + 1220%A  + 705%A  - 285%A  + 1512%A
    +
```
We see that the zeros of our regular chain are split into three components. This is due to the use of univariate polynomial factorization.

Each of these components consists of two parts. The first one is an irreducible univariate polynomial $p(\%)$ which defines a simple algebraic extension of the field of fractions of $R$. The second one consists of multivariate polynomials $\text{pol1}(x,\%), \text{pol2}(y,\%)$ and $\text{pol3}(z,\%)$. Each of these polynomials involves two variables: one is an indeterminate $x$, $y$ or $z$ of the input system $lp$ and the other is $\%$ which represents any root of $p(\%)$. Recall that this $\%$ is the last element of the third parameter of ZDSOLVE. Thus any complex root $\%$ of $p(\%)$ leads to a solution of the input system $lp$ by replacing $\%$ by this $\%$ in $\text{pol1}(x,\%), \text{pol2}(y,\%)$ and $\text{pol3}(z,\%)$. Note that these polynomials $\text{pol1}(x,\%), \text{pol2}(y,\%)$ and $\text{pol3}(z,\%)$ have degree one w.r.t. $x$, $y$ or $z$ respectively. This is always the case for all univariate representations. Hence the operation $\text{univariateSolve}$ replaces a system of multivariate polynomials by a list of univariate polynomials, what justifies its name. Another example of univariate representations illustrates the LexTriangularPackage package constructor.

We now compute the solutions with real coordinates:

```plaintext
lr := realSolve(lp)$pack
[ [\%1, 
  [1184459 19 2335702 18 5460230 17 79900378 16
   -------- \%1 - -------- \%1 - -------- \%1 + -------- \%1
  1645371 548457 182819 1645371
] ]
```

</table>
The number of real solutions for the input system is:

```
# lr
8
```

Each of these real solutions is given by a list of elements in RealClosure(R). In these 8 lists, the first element is a value of z, the second of y and the last of x. This is logical since by setting the list of variables of the package to [x,y,z,t] we mean that the elimination ordering on the variables is t < z < y < x. Note that each system treated by the ZDSOLVE package constructor needs only to be zero-dimensional w.r.t. the variables involved in the system itself and not necessarily w.r.t. all the variables used to define the package.

We can approximate these real numbers as follows. This computation
takes between 30 sec. and 5 min, depending on your machine.

\[
\text{[approximate}(r,1/100000) \text{ for } r \text{ in point] for point in lr}]
\]

We can also concentrate on the solutions with real (strictly) positive coordinates:

\[
\text{lpr := positiveSolve(lp)$pack}
\]

Type: List List RealClosure Fraction Integer

Thus we have checked that the input system has no solution with strictly positive coordinates.

Let us define another polynomial system (L-3).

\[
f_0 := x^3 + y + z + t - 1
\]

\[
z + y + x + t - 1
\]

Type: Polynomial Integer

\[
f_1 := x + y^3 + z + t - 1
\]

Type: Polynomial Integer
\[ z + y + x + t - 1 \]

Type: Polynomial Integer

\[ f_2 := x + y + z^3 + t - 1 \]

\[ z + y + x + t - 1 \]

Type: Polynomial Integer

\[ f_3 := x + y + z + t^3 - 1 \]

\[ z + y + x + t - 1 \]

Type: Polynomial Integer

\[ l_1 := [f_0, f_1, f_2, f_3] \]

\[ z + y + x + t - 1, z + y + x + t - 1, z + y + x + t - 1, z + y + x + t - 1 \]

Type: List Polynomial Integer

First compute a decomposition into regular chains (i.e. regular triangular sets).

\[ lts := \text{triangSolve}(l_1) \]

\[
\begin{align*}
2 & 3 & 3 \\
\{t + t + 1, & 3 & z - z - t + t, \\

5 4 3 2 \\
25218z + 23A + 49A - 46A + 362A + 7594A - 8239, \\
5 4 3 2 \\
12609t + 23A + 49A - 46A + 362A - 5015A - 8239
\end{align*}
\]

\[
\begin{align*}
\text{complexRoots} &= \sqrt[5]{12? + 12\sqrt[5]{16? + 48\sqrt[5]{96}},} \\
\text{coordinates} &= [8x + \%A + 8\%A - 8, 2y - \%A, 2z - \%A, 2t - \%A] \\
\end{align*}
\]

\[
\begin{align*}
\text{complexRoots} &= \sqrt[5]{12? - 5? - 3? + 9? + 3}, \\
\text{coordinates} &= [2x - \%A + 2\%A - 1, 2y + \%A - 4\%A + 1, 2z - \%A + 2\%A - 1, 2t - \%A + 2\%A - 1] \\
\end{align*}
\]

\[
\begin{align*}
\text{complexRoots} &= \sqrt[5]{12? - 11? + 37}, \\
\text{coordinates} &= [3x - \%A + 7, 6y + \%A + 3\%A - 7, 3z - \%A + 7, 6t + \%A - 3\%A - 7] \\
\end{align*}
\]

\[
\begin{align*}
\text{complexRoots} &= \sqrt[5]{12? + 1}, \\
\text{coordinates} &= [x - 1, y, z - 1, t + 1] \\
\text{complexRoots} &= \sqrt[5]{12? + 2}, \\
\text{coordinates} &= [x, y - 1, z - 1, t + 1] \\
\text{complexRoots} &= \sqrt[5]{12? - 2}, \\
\text{coordinates} &= [x, y - 1, z + 1, t - 1] \\
\text{complexRoots} &= \sqrt[5]{12?}, \\
\text{coordinates} &= [x, y + 1, z - 1, t - 1]
\end{align*}
\]
Note that this computation is made from the input system lf.

However it is possible to reuse a pre-computed regular chain as follows:

```plaintext
ts := lts.1
{t + t + 1, z - z - t + t,
(3z + 3t - 3)y + (3z + (6t - 6)z + 3t - 6t + 3)y + (3t - 3)z +
```
We compute now the full set of points with real coordinates:

```plaintext
lr2 := realSolve(lf)$pack
[[0,-1,1,1], [0,0,1,0], [1,0,0,0], [0,0,0,1], [0,1,0,0], [1,0,%B37,-%B37], [1,0,%B38,-%B38], [0,1,%B35,-%B35], [0,1,%B36,-%B36], [-1,0,1,1], [%B32,

The number of real solutions for the input system is:

```
#lr2
27
Type: PositiveInteger
```

Another example of computation of real solutions illustrates the `LexTriangularPackage` package constructor.

We concentrate now on the solutions with real (strictly) positive coordinates:

```
lpr2 := positiveSolve(lf)$pack
[[%B40,- %B40 + -, - - %B40 + -, - %B40 + -],
 3 3 3 3 3 3 3
Type: List List RealClosure Fraction Integer
```

Finally, we approximate the coordinates of this point with 20 exact digits:

```
[approximate(r,1/10**21)::Float for r in lpr2.1]
[0.3221853546 2608559291, 0.3221853546 2608559291, 0.3221853546 2608559291, 0.3221853546 2608559291]
```
ZeroDimensionalSolvePackage (ZDSOLVE)

Exports:
convert positiveSolve realSolve squareFree triangSolve univariateSolve
++ The lexTriangular algorithm can also be used for computing these
++ decompositions (see \spadtype{LexTriangularPackage} package constructor).
++ For that purpose, the operations univariateSolve, realSolve and
++ positiveSolve admit an optional argument.

Exports == with
  triangSolve: (LP,B,B) -> List RegularChain(R,ls)
    ++ \spad{triangSolve(lp,info?,lextri?)} decomposes the variety
    ++ associated with \axiom{lp} into regular chains.
    ++ Thus a point belongs to this variety iff it is a regular
    ++ zero of a regular set in in the output.
    ++ Note that \axiom{lp} needs to generate a zero-dimensional ideal.
    ++ If \axiom{lp} is not zero-dimensional then the result is only
    ++ a decomposition of its zero-set in the sense of the closure
    ++ (w.r.t. Zarisky topology).
    ++ Moreover, if \spad{info?} is \spad{true} then some information is
    ++ displayed during the computations.
++ See zeroSetSplit from RegularTriangularSetCategory(lp,true,info?).
++ If \spad{lextri?} is \spad{true} then the lexTriangular algorithm
++ is called
++ from the \spadtype{LexTriangularPackage} constructor
++ (see zeroSetSplit from LexTriangularPackage(lp,false)).
++ Otherwise, the triangular decomposition is computed directly from
++ the input
++ system by using the zeroSetSplit from RegularChain
triangSolve: (LP,B) -> List RegularChain(R,ls)
++ \spad{triangSolve(lp,info?)} returns the same as
++ \spad{triangSolve(lp,false)}
triangSolve: LP -> List RegularChain(R,ls)
++ \spad{triangSolve(lp)} returns the same as
++ \spad{triangSolve(lp,false,false)}
univariateSolve: RegularChain(R,ls) -> _
++ \spad{univariateSolve(ts)} returns a univariate representation
++ of \spad{ts}.
++ See rur from RationalUnivariateRepresentationPackage(lp,true).
univariateSolve: (LP,B,B,B) -> List RUR
++ \spad{univariateSolve(lp,info?,check?,lextri?)} returns a univariate
++ representation of the variety associated with \spad{lp}.
++ Moreover, if \spad{info?} is \spad{true} then some information is
++ displayed during the decomposition into regular chains.
++ If \spad{check?} is \spad{true} then the result is checked.
++ See rur from RationalUnivariateRepresentationPackage(lp,true).
++ If \spad{lextri?} is \spad{true} then the lexTriangular
++ algorithm is called
++ from the \spadtype{LexTriangularPackage} constructor
++ (see zeroSetSplit from LexTriangularPackage(lp,false)).
++ Otherwise, the triangular decomposition is computed directly
++ from the input
++ system by using the zeroSetSplit from RegularChain

Bibliography
Abstract: A four-parameter fit is developed for the class of integrals known as the exponential integral (real branch). Unlike other fits that are piecewise in nature, the current fit to the exponential integral is valid over the complete domain of the function (compact) and is everywhere accurate to within ±0.0052% when evaluating the first exponential integral, \( E_1 \). To achieve this result, a methodology that makes use of analytically known limiting behaviors at either extreme of the domain is employed. Because the fit accurately captures limiting behaviors of the \( E_1 \) function, more accuracy is retained when the fit is used as part of the scheme to evaluate higher-order exponential integrals, \( E_n \), as compared with the use of brute-force fits to \( E_1 \), which fail to accurately model limiting behaviors. Furthermore, because the fit is compact, no special accommodations are required (as in the case of spliced piecewise fits) to smooth the value, slope, and higher derivatives in the transition region between two piecewise domains. The general methodology employed to develop this fit is outlined, since it may be used for other problems as well.
