Coordinate System Transformations

— ug07.ht —

The \axiomType{CoordinateSystems} package provides coordinate transformation functions that map a given data point from the
coordinate system specified into the Cartesian coordinate system. The
default coordinate system, given a triplet \( f(u, v), u, v \), assumes that \( z = f(u, v) \), \( x = u \) and \( y = v \),
that is, reads the coordinates in \( z, x, y \) order.

\[
\text{m(u:DFLOAT,v:DFLOAT):DFLOAT == u**2}
\]

Graph plotted in default coordinate system.

\[
\text{draw(m,0..3,0..5)}
\]

The \( z \) coordinate comes first since the first argument of the
\text{axiomFun(draw)} command gives its values. In general, the coordinate
systems Axiom provides, or any that you make up, must provide a map to
an \( x, y, z \) triplet in order to be compatible with the
\text{axiomFunFrom(coordinates}{DrawOption} \axiomType{DrawOption}. Here
is an example.

Define the identity function.

\[
\text{cartesian(point:Point DFLOAT):Point DFLOAT == point}
\]

Pass \text{cartesian} as the \text{axiomFunFrom(coordinates}{DrawOption}
parameter to the \text{axiomFun(draw)} command.

Pass \text{cartesian} as the \text{axiomFunFrom(coordinates}{DrawOption}
parameter to the \text{axiomFun(draw)} command.

What happened? The option \text{coordinates == cartesian} directs
Axiom to treat the dependent variable \text{m} defined by
\( m = u^2 \) as the \text{x} coordinate. Thus the triplet
of values \text{x}(m, u, v) is transformed to coordinates
\text{x}(x, y, z) and so we get the graph of \( x = y^2 \).

Here is another example.
The \text{axiomFunFrom(cylindrical)}\{CoordinateSystems\} transform takes
input of the form \text{axiom}(w,u,v), interprets it in the order
\text{x}$and maps it to the Cartesian coordinates
\text{x} = r \cos(\theta), \text{y} = r \sin(\theta), \text{z} = \text{z}
in which $r$ is the radius, $\theta$ is the angle and $z$ is the z-coordinate.

An example using the \text{axiomFunFrom{cylindrical}}\text{CoordinateSystems} coordinates for the constant $r = 3$.

\spadpaste{f(u:DFLOAT,v:DFLOAT):DFLOAT == 3 \bound{f}}

Graph plotted in cylindrical coordinates.

\spadpaste{draw(f,0..\%pi,0..6,coordinates==cylindrical) \free{f}}

Suppose you would like to specify $z$ as a function of $r$ and $\theta$ instead of just $r$? Well, you still can use the \text{axiomFun{cylindrical}} Axiom transformation but we have to reorder the triplet before passing it to the transformation.

First, let's create a point to work with and call it \text{axiom{pt}} with some color \text{axiom{col}}.
\spadpaste{col := 5 \bound{c}}
\spadpaste{pt := point[1,2,3,col] \free{c} \bound{pt}}
The reordering you want is $(z,r,\theta)$ to $(r,\theta,z)$ so that the first element is moved to the third element, while the second and third elements move forward and the color element does not change.

Define a function \text{userfun{reorder}} to reorder the point elements.
\spadpaste{reorder(p:Point DFLOAT):Point DFLOAT == point[p.2, p.3, p.1, p.4] \bound{freo}}
The function moves the second and third elements forward but the color does not change.

```
\spadpaste{reorder pt \free{pt freo}}
```

The function \userfun{newmap} converts our reordered version of the cylindrical coordinate system to the standard \texht{$(x,y,z)$}{\axiom{(x,y,z)}} Cartesian system.

```
\spadpaste{newmap(pt:Point DFLOAT):Point DFLOAT == cylindrical(reorder pt) \free{fnewmap}}
```

Graph the same function \axiom{f} using the coordinate mapping of the function \axiom{newmap}, so it is now interpreted as \texht{$z=3$}{\axiom{z = 3}}:

```
\graphpaste{draw(f,0..3,0..2*\%pi,coordinates==newmap) \free{f new}}
```

The \axiomType{CoordinateSystems} package exports the following operations:
\axiomFun{bipolar}, \axiomFun{bipolarCylindrical}, \axiomFun{cartesian}, \axiomFun{conical}, \axiomFun{cylindrical}, \axiomFun{elliptic}, \axiomFun{ellipticCylindrical}, \axiomFun{oblateSpheroidal}, \axiomFun{parabolic}, \axiomFun{parabolicCylindrical}, \axiomFun{paraboloidal}, \axiomFun{polar}, \axiomFun{prolateSpheroidal}, \axiomFun{spherical}, and \axiomFun{toroidal}.

Use \Browse{} or the \spadcmd{}\show{} system command to get more information.

Three-Dimensional Clipping

A \threedim{} graph can be explicitly clipped within the \axiomFun{draw} command by indicating a minimum and maximum threshold for the given function definition. These thresholds can be defined using the Axiom \axiomFun{min} and \axiomFun{max} functions.

\xtc{
\begin{spadsrc}
\texttt{gamma(x,y) ==}
\texttt{\quad g := Gamma complex(x,y)
\quad point [x, y, max( min(real g, 4), -4), argument g]}
\end{spadsrc}
}

Here is an example that clips the gamma function in order to eliminate the extreme divergence it creates.

\begin{verbatim}
Type: Void
\end{verbatim}

\psXtc{
\graphpaste{draw(gamma,-\%pi..\%pi,-\%pi..\%pi,\var1Steps==50,\var2Steps==50) \free{g}}
}

\epsffile[0 0 295 295]{../ps/clipgamma.ps}

Three-Dimensional Control-Panel

Once you have created a viewport, move your mouse to the viewport and click with your left mouse button. This displays a control-panel on the side of the viewport that is closest to where you clicked.

We recommend you first select the \( \textbf{Bounds} \) button while executing transformations since the bounding box displayed indicates the object’s position as it changes.

\item[\textbf{Rotate:}] A rotation transformation occurs by clicking the mouse within the \( \textbf{Rotate} \) window in the upper left corner of the control-panel.
The rotation is computed in spherical coordinates, using the horizontal mouse position to increment or decrement the value of the longitudinal angle $\theta$ within the range of 0 to $2\pi$ and the vertical mouse position to increment or decrement the value of the latitudinal angle $\phi$ within the range of $-\pi$ to $\pi$. The active mode of rotation is displayed in green on a color monitor or in clear text on a black and white monitor, while the inactive mode is displayed in red for color display or a mottled pattern for black and white.

\item[origin:] The \textbf{origin} button indicates that the rotation is to occur with respect to the origin of the viewing space, that is indicated by the axes.

\item[object:] The \textbf{object} button indicates that the rotation is to occur with respect to the center of volume of the object, independent of the axes' origin position.

\item[Scale:] A scaling transformation occurs by clicking the mouse within the \textbf{Scale} window in the upper center of the control-panel, containing a zoom arrow. The axes along which the scaling is to occur are indicated by selecting the appropriate button above the zoom arrow window. The selected axes are displayed in green on a color monitor or in clear text on a black and white monitor, while the unselected axes are displayed in red for color display or a mottled pattern for black and white.

\item[uniform:] Uniform scaling along the \texttt{x}, \texttt{y} and \texttt{z} axes occurs when all the axes buttons are selected.

\item[non-uniform:] If any of the axes buttons are not selected, non-uniform scaling occurs, that is, scaling occurs only in the direction of the axes that are selected.

\item[Translate:] Translation occurs by indicating with the mouse in the \textbf{Translate} window the direction you want the graph to move. This window is located in the upper right corner of the control-panel.
and contains a potentiometer with crossed arrows pointing up, down, left and right. Along the top of the \textbf{\textit{Translate}} window are three buttons (\textbf{XY}, \textbf{XZ}, and \textbf{YZ}) indicating the three orthographic projection planes. Each orientates the group as a view into that plane. Any translation of the graph occurs only along this plane.

\subsection*{Messages}

The window directly below the potentiometer windows for transformations is used to display system messages relating to the viewport, the control-panel and the current graph displaying status.

\subsection*{Colormap}

Directly below the message window is the colormap range indicator window. The Axiom Colormap shows a sampling of the spectrum from which hues can be drawn to represent the colors of a surface. The Colormap is composed of five shades for each of the hues along this spectrum. By moving the markers above and below the Colormap, the range of hues that are used to color the existing surface are set. The bottom marker shows the hue for the low end of the color range and the top marker shows the hue for the upper end of the range. Setting the bottom and top markers at the same hue results in monochromatic smooth shading of the graph when \textbf{Smooth} mode is selected. At each end of the Colormap are \textbf{+} and \textbf{-} buttons. When clicked on, these increment or decrement the top or bottom marker.

\subsection*{Buttons}

Below the Colormap window and to the left are located various buttons that determine the characteristics of a graph. The buttons along the bottom and right hand side all have special meanings; the remaining buttons in the first row indicate the mode or style used to display the graph. The second row are toggles that turn on or off a property of the graph.

On a color monitor, the property is on if green (clear text, on a monochrome monitor) and off if red (mottled pattern, on a monochrome monitor).

Here is a list of their functions.

\item \textbf{Wire} displays surface and tube plots as a wireframe image in a single color (blue) with no hidden surfaces removed, or displays space curve plots in colors based upon their parametric variables. This is
the fastest mode for displaying a graph. This is very useful when you want to find a good orientation of your graph.

\item[Solid] displays the graph with hidden surfaces removed, drawing each polygon beginning with the furthest from the viewer. The edges of the polygons are displayed in the hues specified by the range in the Colormap window.

\item[Shade] displays the graph with hidden surfaces removed and with the polygons shaded, drawing each polygon beginning with the furthest from the viewer. Polygons are shaded in the hues specified by the range in the Colormap window using the Phong illumination model.

\item[Smooth] displays the graph using a renderer that computes the graph one line at a time. The location and color of the graph at each visible point on the screen are determined and displayed using the Phong illumination model.

Smooth shading is done in one of two ways, depending on the range selected in the colormap window and the number of colors available from the hardware and/or window manager. When the top and bottom markers of the colormap range are set to different hues, the graph is rendered by dithering between the transitions in color hue. When the top and bottom markers of the colormap range are set to the same hue, the graph is rendered using the Phong smooth shading model. However, if enough colors cannot be allocated for this purpose, the renderer reverts to the color dithering method until a sufficient color supply is available. For this reason, it may not be possible to render multiple Phong smooth shaded graphs at the same time on some systems.

\item[Bounds] encloses the entire volume of the viewgraph within a bounding box, or removes the box if previously selected. The region that encloses the entire volume of the viewport graph is displayed.

\item[Axes] displays Cartesian coordinate axes of the space, or turns them off if previously selected.

\item[Outline] causes quadrilateral polygons forming the graph surface to be outlined in black when the graph is displayed in {\bf Shade} mode.

\item[BW] converts a color viewport to black and white, or vice-versa. When this button is selected the control-panel and viewport switch to an immutable colormap composed of a range of grey scale patterns or tiles that are used wherever shading is necessary.
\item[Light] takes you to a control-panel described below.
\%
\item[ViewVolume] takes you to another control-panel as described below.

\item[Save] creates a menu of the possible file types that can be written using the control-panel. The \{bf Exit\} button leaves the save menu. The \{bf Pixmap\} button writes an Axiom pixmap of the current viewport contents. The file is called \{bf axiom3D.pixmap\} and is located in the directory from which Axiom or \{bf viewalone\} was started. The \{bf PS\} button writes the current viewport contents to PostScript output rather than to the viewport window. By default the file is called \{bf axiom3D.ps\}; however, if a file name is specified in the user's \{bf .Xdefaults\} file it is used. The file is placed in the directory from which the Axiom or \{bf viewalone\} session was begun. See also the \axiomFunFrom{write}{ThreeDimensionalViewport} function.

\item[Reset] returns the object transformation characteristics back to their initial states.
\%
\item[Hide] causes the control-panel for the corresponding viewport to disappear from the screen.
\%
\item[Quit] queries whether the current viewport session should be terminated.
\enditems
\indent{0}

\subsubsection{Light}

The \{bf Light\} button changes the control-panel into the \{bf Lighting Control-Panel\}. At the top of this panel, the three axes are shown with the same orientation as the object. A light vector from the origin of the axes shows the current position of the light source relative to the object. At the bottom of the panel is an \{bf Abort\} button that cancels any changes to the lighting that were made, and a \{bf Return\} button that carries out the current set of lighting changes on the graph.
\%
\indent{0}
\beginitems
\%
\item[XY:] The \{bf XY\} lighting axes window is below the \{bf Lighting Control-Panel\} title and to the left. This changes the light vector within the \{bf XY\} view plane.
\%
\item[Z:] The \{bf Z\} lighting axis window is below the \{bf Lighting Control-Panel\} title and in the center. This changes the \{bf Z\}
location of the light vector.
\item[Intensity:]
Below the {\bf Lighting Control-Panel} title
and to the right is the light intensity meter.
Moving the intensity indicator down decreases the amount of
light emitted from the light source.
When the indicator is at the top of the meter the light source is
emitting at 100\% intensity.
At the bottom of the meter the light source is emitting at a level
slightly above ambient lighting.
\enditems
\indent{0}
\subsubsection{View Volume}
The {\bf View Volume} button changes the control-panel into
the {\bf Viewing Volume Panel}.
At the bottom of the viewing panel is a {\bf Abort} button that
cancels any changes to the viewing volume that were made and a
{\it Return} button that carries out the current set of
viewing changes to the graph.
\indent{0}
\beginitems
\item[Eye Reference:] At the top of this panel is the {\bf Eye
Reference} window. It shows a planar projection of the viewing
pyramid from the eye of the viewer relative to the location of the
object. This has a bounding region represented by the rectangle on
the left. Below the object rectangle is the {\bf Hither} window. By
moving the slider in this window the hither clipping plane sets the
front of the view volume. As a result of this depth clipping all
points of the object closer to the eye than this hither plane are not
shown. The {\bf Eye Distance} slider to the right of the {\bf Hither}
slider is used to change the degree of perspective in the image.
\item[Clip Volume:] The {\bf Clip Volume} window is at the bottom of
the {\bf Viewing Volume Panel}. On the right is a {\bf Settings}
menu. In this menu are buttons to select viewing attributes.
Selecting the {\bf Perspective} button computes the image using
perspective projection. The {\bf Show Region} button indicates
whether the clipping region of the volume is to be drawn in the
viewport and the {\bf Clipping On} button shows whether the view
volume clipping is to be in effect when the image is drawn. The left
side of the {\bf Clip Volume} window shows the clipping boundary of
the graph. Moving the knobs along the {\bf X}, {\bf Y}, and {\bf Z}
sliders adjusts the volume of the clipping region accordingly.
\enditems
\indent{0}
Here is a summary of useful Axiom operations for \threedim{} graphics. Each operation name is followed by a list of arguments. Each argument is written as a variable informally named according to the type of the argument (for example, \{\it integer\}). If appropriate, a default value for an argument is given in parentheses immediately following the name.

\begin{itemize}
\item \axiomFun{adaptive3D?}\funArgs{} tests whether space curves are to be plotted according to the adaptive refinement algorithm.
\item \axiomFun{axes}\funArgs{viewport, string\argDef{"on"}} turns the axes on and off.
\item \axiomFun{close}\funArgs{viewport} closes the viewport.
\item \axiomFun{colorDef}\funArgs{viewport, \subscriptIt{color}{1}\argDef{1}, \subscriptIt{color}{2}\argDef{27}} sets the colormap range to be from \subscriptIt{color}{1} to \subscriptIt{color}{2}.
\item \texttt{controlPanel(viewport, string \textbackslash argDef{"off"})} declares whether the control-panel for the viewport is to be displayed or not.

\item \texttt{diagonals(viewport, string \textbackslash argDef{"off"})} declares whether the polygon outline includes the diagonals or not.

\item \texttt{drawStyle(viewport, style)} selects which of four drawing styles are used: \{\texttt{"wireMesh"", "solid", "shade"},\} or \{\texttt{"smooth".}\}

\item \texttt{eyeDistance(viewport, float \textbackslash argDef{500})} sets the distance of the eye from the origin of the object for use in the \texttt{perspective(ThreeDimensionalViewport)}. 

\item \texttt{key(viewport)} returns the operating system process ID number for the viewport.

\item \texttt{lighting(viewport, float \textbackslash x\argDef{-0.5}, \textbackslash y\argDef{0.5}, \textbackslash z\argDef{0.5})} sets the Cartesian coordinates of the light source.

\item \texttt{modifyPointData(viewport, integer, point)} replaces the coordinates of the point with the index \{\texttt{integer} with \{\texttt{point}.\}

\item \texttt{move(viewport, integer \textbackslash x\argDef{viewPosDefault}, integer \textbackslash y\argDef{viewPosDefault})} moves the upper left-hand corner of the viewport to screen position

\item \texttt{options(viewport)} returns a list of all current draw options.
% \item[\axiomFun{outlineRender}] funArgs{viewport, string\argDef{"off"}}
turns polygon outlining
off or on when drawing in \{\tt "shade"\} mode.

% \item[\axiomFun{perspective}] funArgs{viewport, string\argDef{"on"}}
turns perspective
viewing on and off.

% \item[\axiomFun{reset}] funArgs{viewport}
resets the attributes of a viewport to their
initial settings.

% \item[\axiomFun{resize}] funArgs{viewport,
\subscriptText{integer}{width} \argDef{viewSizeDefault},
\subscriptText{integer}{height} \argDef{viewSizeDefault}}
resets the width and height
values for a viewport.

% \item[\axiomFun{rotate}] funArgs{viewport,
\subscriptText{number}{\texht{$\theta$}{\axiom{theta}}} \argDef{viewThetaDefault},
\subscriptText{number}{\texht{$\phi$}{\axiom{phi}}} \argDef{viewPhiDefault}}
rotates the viewport by rotation angles for longitude
\{\it \texht{$\theta$}{\axiom{theta}}\} and
latitude \{\it \texht{$\phi$}{\axiom{phi}}\}.
Angles designate radians if given as floats, or degrees if given
as integers.

% \item[\axiomFun{setAdaptive3D}] funArgs{boolean\argDef{true}}
sets whether space curves are to be plotted
according to the adaptive
refinement algorithm.

% \item[\axiomFun{setMaxPoints3D}] funArgs{integer\argDef{1000}}
sets the default maximum number of possible
points to be used when constructing a \threedim{} space curve.

% \item[\axiomFun{setMinPoints3D}] funArgs{integer\argDef{49}}
sets the default minimum number of possible
points to be used when constructing a \threedim{} space curve.
\item \texttt{setScreenResolution3D}\funArgs{integer\argDef{500}}
sets the default screen resolution constant 
used in setting the computation limit of adaptively 
generated \texttt{threedim} space curve plots.

\item \texttt{showRegion}\funArgs{viewport, string\argDef{"off"}}
declares whether the bounding 
box of a graph is shown or not.

\item \texttt{subspace}\funArgs{viewport}
returns the space component.

\item \texttt{subspace}\funArgs{viewport, subspace}
resets the space component 
to \texttt{it subspace}.

\item \texttt{title}\funArgs{viewport, string}
gives the viewport the 
title \texttt{it string}.

\item \texttt{translate}\funArgs{viewport, 
\subscriptText{float}{x}\argDef{viewDeltaXDefault}, 
\subscriptText{float}{y}\argDef{viewDeltaYDefault}}
translates the object horizontally and vertically 
relative to the center of the viewport.

\item \texttt{intensity}\funArgs{viewport, float\argDef{1.0}}
resets the intensity \texttt{I} of the light source, 
\texttt{\(0 \leq I \leq 1\)}.

\item \texttt{tubePointsDefault}\funArgs{optArg{integer\argDef{6}}}
sets or indicates the default number of 
vertices defining the polygon that is used to create a tube around 
a space curve.

\item \texttt{tubeRadiusDefault}\funArgs{optArg{float\argDef{0.5}}}
sets or indicates the default radius of 
the tube that encircles a space curve.

\item \texttt{var1StepsDefault}\funArgs{optArg{integer\argDef{27}}}
sets or indicates the default number of 
increments into which the grid defining a surface plot is subdivided with
respect to the first parameter declared in the surface function.

% 
\item[\axiomFun{var2StepsDefault}]{\funArgs{\optArg{integer\argDef{27}}}}
sets or indicates the default number of
increments into which the grid defining a surface plot is subdivided with
respect to the second parameter declared in the surface function.

% 
\item[\axiomFun{viewDefaults}]{\funArgs{{\tt [}\subscriptText{integer}{\tt point}, \subscriptText{integer}{\tt line}, \subscriptText{integer}{\tt axes}, \subscriptText{float}{\tt point}, \allowbreak \subscriptText{list}{\tt position}, \subscriptText{list}{\tt size}}{{\tt ]}}}
resets the default settings for the
point color, line color, axes color, units color, point size,
viewport upper left-hand corner position, and the viewport size.

% 
\item[\axiomFun{viewDeltaXDefault}]{\funArgs{\optArg{float\argDef{0}}}}
resets the default horizontal offset
from the center of the viewport, or returns the
current default offset if no argument is given.

% 
\item[\axiomFun{viewDeltaYDefault}]{\funArgs{\optArg{float\argDef{0}}}}
resets the default vertical offset
from the center of the viewport, or returns the
current default offset if no argument is given.

% 
\item[\axiomFun{viewPhiDefault}]{\funArgs{\optArg{float \argDef{-\frac{\pi}{4}}}}}
resets the default latitudinal view angle,
or returns the current default angle if no argument is given.
\texttt{$\phi$} is set to this value.

% 
\item[\axiomFun{viewpoint}]{\funArgs{\subscriptText{float}{x}, \subscriptText{float}{y}, \subscriptText{float}{z}}}
sets the viewing position in Cartesian coordinates.

% 
\item[\axiomFun{viewpoint}]{\funArgs{\subscriptText{float}{$\theta$}, \subscriptText{Float}{$\phi$}}}
sets the viewing position in spherical coordinates.
sets the viewing position in spherical coordinates, the scale factor, and offsets. 

\[ $\theta$ \] (longitude) and \[ $\phi$ \] (latitude) are in radians.

\item \( \text{viewPosDefault} \) \funArgs{\optArg{list\argDef{[0,0]}}} sets or indicates the position of the upper left-hand corner of a \twodim{} viewport, relative to the display root window (the upper left-hand corner of the display is \axiom{[0, 0]}).

\item \( \text{viewSizeDefault} \) \funArgs{\optArg{list\argDef{[400,400]}}} sets or indicates the width and height dimensions of a viewport.

\item \( \text{viewThetaDefault} \) \funArgs{\optArg{float\argDef{\text{\it pi}/4}}} resets the default longitudinal view angle, or returns the current default angle if no argument is given. When a parameter is specified, the default longitudinal view angle \[ $\theta$ \] is set to this value.

\item \( \text{viewWriteAvailable} \) \funArgs{\optArg{list\argDef{\{"pixmap", "bitmap", "postscript", "image"}}} indicates the possible file types that can be created with the \axiomFunFrom{write}{ThreeDimensionalViewport} function.

\item \( \text{viewWriteDefault} \) \funArgs{\optArg{list\argDef{[]}}} sets or indicates the default types of files that are created in addition to the \{\bf data\} file when a \axiomFunFrom{write}{ThreeDimensionalViewport} command is executed on a viewport.

\item \( \text{viewScaleDefault} \) \funArgs{\optArg{float}} sets the default scaling factor, or returns the current factor if no argument is given.

\item \( \text{write} \) \funArgs{viewport, directory, \optArg{option}}
writes the file \texttt{data} for \texttt{viewport} in the directory \texttt{directory}.
An optional third argument specifies a file type (one of \texttt{pixmap}, \texttt{bitmap}, \texttt{postscript}, or \texttt{image}), or a list of file types.
An additional file is written for each file type listed.

\item \texttt{axiomFun{scale}} \funArgs{viewport, float\argDef{2.5}} specifies the scaling factor.

\begin{page}{ugProblemPage}{8. Advanced Problem Solving}
\beginscroll

In this chapter we describe techniques useful in solving advanced problems with Axiom.

\beginmenu
\menusdownlink{{8.1. Numeric Functions}}
{ugProblemNumericPage}

2077
Axiom provides two basic floating-point types: \axiomType{Float} and \
\axiomType{DoubleFloat}. This section describes how to use numerical 
operations defined on these types and the related complex 
types.

As we mentioned in """ in Chapter, the \axiomType{Float} type is a 
software implementation of floating-point numbers in which 
the exponent and the significand may have any number of digits. See 'Float' for detailed information about this domain. The 
\axiomType{DoubleFloat} (see 'DoubleFloat') is usually a hardware 
implementation of floating point numbers, corresponding to 
machine double precision. The types \axiomType{Complex Float} and 
\axiomType{Complex DoubleFloat} are the corresponding software 
implementations of complex floating-point numbers. In this 
section the term floating-point type means any of these four 
types.

The floating-point types implement the basic elementary 
functions. These include (where """ means \axiomType{DoubleFloat}. 

← “Axiom Number Types” (NumberPage) 3.80 on page 1021
← “Complex” (ComplexXmpPage) 3.16 on page 254
⇒ “An Overview of Axiom” (ugIntroPage) 6 on page 1483
⇒ “Float” (FloatXmpPage) 3.41 on page 487
⇒ “DoubleFloat” (DoubleFloatXmpPage) 3.23 on page 369
— ug08.ht —
of these four types.

The floating-point types implement the basic elementary functions. These include (where \axiomSyntax{\$} means \\
\axiomType{DoubleFloat}, \\
\axiomType{Float}, \\
\axiomType{Complex DoubleFloat}, or \\
\axiomType{Complex Float}):

\n\n
\axiomFun{exp}, \axiomFun{log}: \axiom{\$ -> \$} \\
\axiomFun{sin}, \axiomFun{cos}, \axiomFun{tan}, \axiomFun{cot}, \\
\axiomFun{sec}, \axiomFun{csc}: \axiom{\$ -> \$} \\
\axiomFun{sin}, \axiomFun{cos}, \axiomFun{tan}, \axiomFun{cot}, \\
\axiomFun{sec}, \axiomFun{csc}: \axiom{\$ -> \$} \\
\axiomFun{asin}, \axiomFun{acos}, \axiomFun{atan}, \axiomFun{acot}, \\
\axiomFun{asec}, \axiomFun{acsc}: \axiom{\$ -> \$} \\
\axiomFun{sinh}, \axiomFun{cosh}, \axiomFun{tanh}, \axiomFun{coth}, \\
\axiomFun{sech}, \axiomFun{csch}: \axiom{\$ -> \$} \\
\axiomFun{asinh}, \axiomFun{acosh}, \axiomFun{atanh}, \axiomFun{acoth}, \\
\axiomFun{asech}, \axiomFun{acsch}: \axiom{\$ -> \$} \\
\axiomFun{pi}: \axiom{() -> \$} \\
\axiomFun{sqrt}: \axiom{\$ -> \$} \\
\axiomFun{nthRoot}: \axiom{\$, \text{Integer} -> \$} \\
\axiomFunFrom{**}{Float}: \axiom{\$, \text{Fraction Integer} -> \$} \\
\axiomFunFrom{**}{Float}: \axiom{\$, \$ -> \$}

The handling of roots depends on whether the floating-point type 

is real or complex: for the real floating-point types, 

\axiomType{DoubleFloat} and \axiomType{Float}, if a real root exists 

the one with the same sign as the radicand is returned; for the 

complex floating-point types, the principal value is returned. 

Also, for real floating-point types the inverse functions 

produce errors if the results are not real. 

This includes cases such as \axiom{asin(1.2)}, \axiom{log(-3.2)}, \\
\axiom{sqrt(-1.1)}.

\xtc{ 
  The default floating-point type is \axiomType{Float} so to evaluate 
  functions using \axiomType{Float} or \axiomType{Complex Float}, just 
  use normal decimal notation. 
}

\spadpaste{exp(3.1)}

\xtc{
  \spadpaste{exp(3.1 + 4.5 * \%i)}
}

To evaluate functions using \axiomType{DoubleFloat}
or \axiomType{Complex DoubleFloat},
a declaration or conversion is required.
){
\spadpaste{r: DFLOAT := 3.1; t: DFLOAT := 4.5; exp(r + t*\%i)}
}\xtc{
}{
\spadpaste{exp(3.1::DFLOAT + 4.5::DFLOAT * \%i)}
}

A number of special functions are provided by the package
\axiomType{DoubleFloatSpecialFunctions} for the machine-precision
floating-point types. The special functions provided are listed
below, where \axiom{F} stands for the types \axiomType{DoubleFloat}
and \axiomType{Complex DoubleFloat}. The real versions of the
functions yield an error if the result is not real.

\noindent \axiomFun{Gamma}: \axiom{F -> F}\newline
\axiom{Gamma(z)} is the Euler gamma function,
\texht{$\Gamma(z)$}{\axiom{Gamma(z)}}, defined by
\texht{
\narrowDisplay{
\Gamma(z) = \int_{0}^{\infty} t^{z-1} e^{-t} dt.}
}\newline
\centerline{{ \axiom{Gamma(z) = integrate(t**(z-1)*exp(-t), t=0..\%infinity).}}}

\noindent \axiomFun{Beta}: \axiom{F -> F}\newline
\axiom{Beta(u, v)} is the Euler Beta function,
\texht{$B(u,v)$}{\axiom{Beta(u,v)}}, defined by
\texht{
\narrowDisplay{B(u,v) = \int_{0}^{1} t^{u-1} (1-t)^{v-1} dt.}
}\newline
\centerline{{ \axiom{Beta(u,v) = integrate(t**(u-1)*(1-t)**(b-1), t=0..1).}}}
\texht{$B(u,v) = \frac{\Gamma(u) \Gamma(v)}{\Gamma(u + v)}$.}{\axiom{Beta(u,v) = Gamma(u)*Gamma(v)/Gamma(u + v).}}

\noindent \axiomFun{logGamma}: \axiom{F -> F}\newline
\axiomFun{Beta}(u, v) = \int_{0}^{1} t^{u-1} (1-t)^{v-1} dt.
\]
\axiom{logGamma(z)} is the natural logarithm of \axiom{Gamma(z)}.
This can often be computed even if \axiom{Gamma(z)} cannot.

\axiomFun{digamma}: \axiom{F -> F}
\axiom{digamma(z)}, also called \axiom{psi(z)}, is the function \axiom{psi(z)}, defined by
\axiom{psi(z) = Gamma'(z)/Gamma(z)}.

\axiomFun{polygamma}: \axiom{(NonNegativeInteger, F) -> F}
\axiom{polygamma(n, z)} is the \eth{n} derivative of \axiom{psi(z)}, written \axiom{psi^n(z)}.

\axiomFun{besselJ}: \axiom{(F, F) -> F}
\axiom{besselJ(v, z)} is the Bessel function of the first kind, \axiom{J_v(z)}.
This function satisfies the differential equation
\axiom{z**2*w''(z) + z*w'(z) + (z**2-v**2)*w(z) = 0}.

\axiomFun{besselY}: \axiom{(F, F) -> F}
\axiom{besselY(v, z)} is the Bessel function of the second kind, \axiom{Y_v(z)}.
This function satisfies the same differential equation as \axiom{besselJ}.
The implementation simply uses the relation
\axiom{Y_v(z) = \frac{J_v(z) \cos(v*%pi) - J_{-v}(z)}{\sin(v*%pi)}}.
\noindent \axiomFun{besselI}: \axiom{(F,F) -> F}\hfill\newline
\axiom{besselI(v,z)} is the modified Bessel function of the first kind,
\texht{$I_\nu (z)$}{\axiom{I(v,z)}}. This function satisfies the differential equation
\narrowDisplay{z^2 w''(z) + z w'(z) - (z^2+\nu^2)w(z) = 0.}\%
\newline
\noindent \axiomFun{besselK}: \axiom{(F,F) -> F}\hfill\newline
\axiom{besselK(v,z)} is the modified Bessel function of the second kind,
\texht{$K_\nu (z)$}{\axiom{K(v,z)}}. This function satisfies the same differential equation as \axiomFun{besselI}.
The implementation simply uses the relation
\narrowDisplay{K_\nu (z) = \pi \frac{I_{-\nu} (z) - I_\nu (z)}{2 \sin(\nu \pi)}.}\%
\newline
\noindent \axiomFun{airyAi}: \axiom{F -> F}\hfill\newline
\axiom{airyAi(z)} is the Airy function \texht{$Ai(z)$}{\axiom{Ai(z)}}. This function satisfies the differential equation
\texht{$w''(z) - z w(z) = 0.$}{\axiom{w''(z) - z * w(z) = 0.}}
The implementation simply uses the relation
\narrowDisplay{Ai(-z) = \frac{1}{3} \sqrt{z} \left( J_{-1/3} \left( \frac{2}{3}z^{3/2} \right) + J_{1/3} \left( \frac{2}{3}z^{3/2} \right) \right).}\%
\newline
\noindent \axiomFun{airyBi}: \axiom{F -> F}\hfill\newline
\axiom{airyBi(z)} is the Airy function \texht{$Bi(z)$}{\axiom{Bi(z)}}. This function satisfies the same differential equation as \axiomFun{airyAi}.
The implementation simply uses the relation
\texttt{Bi(-z) = 1/3 *sqrt(3*z) * (J(-1/3, 2/3*z**(3/2)) - J(1/3, 2/3*z**(3/2)) ).} \\

The above special functions are defined only for small floating-point types. If you give \texttt{Float} arguments, they are converted to \texttt{DoubleFloat} by Axiom.

A number of additional operations may be used to compute numerical values. These are special polynomial functions that can be evaluated for values in any commutative ring \texttt{R}, and in particular for values in any floating-point type. The following operations are provided by the package \texttt{OrthogonalPolynomialFunctions}:

\texttt{chebyshevT}:
\texttt{(NonNegativeInteger, R) -> R} \\
\texttt{chebyshevT(n,z)} is the \eth{n} Chebyshev polynomial of the first kind, \texttt{T_n(z)}. These are defined by
\texttt{\sum_{n=0}^{\infty} T_n(z) t^n}. 

\texttt{chebyshevU}:
\texttt{(NonNegativeInteger, R) -> R} \\
\texttt{chebyshevU(n,z)} is the \eth{n} Chebyshev polynomial of the second kind.
Chebyshev polynomial of the second kind, $U_n(z)$. These are defined by
\[ \frac{1}{1-2t z+t^2} = \sum_{n=0}^{\infty} U_n(z) t^n. \]

$\text{hermiteH}$: $(\text{NonNegativeInteger}, \text{R}) \rightarrow \text{R}$
\[ \text{hermiteH}(n, z) \] is the $n$th Hermite polynomial, $H_n(z)$. These are defined by
\[ e^{2t z-t^2} = \sum_{n=0}^{\infty} H_n(z) \frac{t^n}{n!}. \]

$\text{laguerreL}$: $(\text{NonNegativeInteger}, \text{NonNegativeInteger}, \text{R}) \rightarrow \text{R}$
\[ \text{laguerreL}(m, n, z) \] is the associated Laguerre polynomial, $L^m_n(z)$. This is the $m$th derivative of $L_n(z)$.

$\text{legendreP}$: $(\text{NonNegativeInteger}, \text{R}) \rightarrow \text{R}$
\[ \text{legendreP}(n, z) \] is the $n$th Legendre polynomial, $P_n(z)$. These are defined by
\[ e^{-\frac{t z}{1-t}}/(1-t) = \sum_{n=0}^{\infty} L_n(z) \frac{t^n}{n!}. \]
These operations require non-negative integers for the indices, but otherwise the argument can be given as desired.

\spadpaste{[chebyshevT(i, z) for i in 0..5]}

The expression \axiom{chebyshevT(n,z)} evaluates to the \eth{\axiom{n}} Chebyshev polynomial of the first kind.

\spadpaste{chebyshevT(3, 5.0 + 6.0\%i)}

The expression \axiom{chebyshevU(n,z)} evaluates to the \eth{\axiom{n}} Chebyshev polynomial of the second kind.

\spadpaste{chebyshevU(3, 0.2)}

The expression \axiom{hermiteH(n,z)} evaluates to the \eth{\axiom{n}} Hermite polynomial.

\spadpaste{hermiteH(100, 1.0)}

The expression \axiom{laguerreL(n,z)} evaluates to the \eth{\axiom{n}} Laguerre polynomial.

\spadpaste{laguerreL(1, z) for i in 0..4}
The expression \axiom{legendreP(n,z)} evaluates to the \eth{n} Legendre polynomial,
\spadpaste{[legendreP(i,z) for i in 0..5]}
\spadpaste{legendreP(3, 3.0*\%i)}

Finally, three number-theoretic polynomial operations may be evaluated. The following operations are provided by the package \axiomType{NumberTheoreticPolynomialFunctions}.

\indent \axiomFun{bernoulliB}: \axiom{(NonNegativeInteger, R) -> R}
\hfill
\begin{axiom}
\texttt{bernoulliB(n,z)} is the \eth{n} Bernoulli polynomial, \spadpaste{\sum_{n=0}^\infty \frac{t^n}{n!}}.
\end{axiom}
\indent \axiomFun{eulerE}: \axiom{(NonNegativeInteger, R) -> R}
\begin{axiom}
\texttt{eulerE(n,z)} is the \eth{n} Euler polynomial, \spadpaste{\sum_{n=0}^\infty \frac{2 e^{z t}}{e^t + 1} \frac{t^n}{n!}}.
\end{axiom}
\newline
\centerline{{ \axiom{2*exp(z*t)/(exp t + 1) =}}}
\centerline{{ \sum(E[n](z)*t**n/n! \text{ for } n = 0..)}}}
\% 

\noindent \axiomFun{cyclotomic}: \axiom{((\text{NonNegativeInteger}, \text{R}) \rightarrow \text{R})}
\hfill
\newline
\axiom{cyclotomic(n,z)} is the \eth{\axiom{n}} cyclotomic polynomial 
\texht{$\Phi_n (z)$}{\axiom{phi(n,z)}}. This is the polynomial whose 
roots are precisely the primitive \eth{\axiom{n}} roots of unity. 
This polynomial has degree given by the Euler totient function 
\texht{$\phi(n)$}{\axiom{phi(n)}}.

\xtc{The expression \axiom{bernoulliB(n,z)} evaluates to the \eth{\axiom{n}} Bernoulli polynomial.}{\spadpaste{bernoulliB(3, z)}}
\xtc{\axiom{bernoulliB(3, 0.7 + 0.4 * \%i)}}

\xtc{The expression \axiom{eulerE(n,z)} evaluates to the \eth{\axiom{n}} Euler polynomial.}{\spadpaste{eulerE(3, z)}}
\xtc{\axiom{eulerE(3, 0.7 + 0.4 * \%i)}}

\xtc{The expression \axiom{cyclotomic(n,z)} evaluates to the \eth{\axiom{n}} cyclotomic polynomial.}{\spadpaste{cyclotomic(3, z)}}
\xtc{\axiom{cyclotomic(3, (-1.0 + 0.0 * \%i)**(2/3))}}

Drawing complex functions in Axiom is presently somewhat awkward compared to drawing real functions. It is necessary to use the \axiomFun{draw} operations that operate on functions rather than expressions.
This is the complex exponential function. When this is displayed in color, the height is the value of the real part of the function and the color is the imaginary part. Red indicates large negative imaginary values, green indicates imaginary values near zero and blue/violet indicates large positive imaginary values.

\graphpaste{draw((x,y) +-> real exp complex(x,y), -2..2, -2*%pi..2*%pi, colorFunction == (x, y) +-> imag exp complex(x,y), title=="exp(x+%i*y)", style=="smooth")}

This is the complex arctangent function. Again, the height is the real part of the function value but here the color indicates the function value's phase. The position of the branch cuts are clearly visible and one can see that the function is real only for a real argument.

\graphpaste{vp := draw((x,y) +-> real atan complex(x,y), -%pi..%pi, -%pi..%pi, colorFunction== (x,y) +-> argument atan complex(x,y), title=="atan(x+%i*y)", style=="shade"); rotate(vp,-160,-45); vp}

This is the complex Gamma function.

\graphpaste{draw((x,y) +-> max(min(real Gamma complex(x,y),4),-4), -%pi..%pi, -%pi..%pi, style=="shade", colorFunction == (x,y) +-> argument Gamma complex(x,y), title == "Gamma(x+%i*y)", var1Steps == 50, var2Steps== 50)}

This shows the real Beta function near the origin.

\graphpaste{draw(Beta(x,y)/100, x=-1.6..1.7, y = -1.6..1.7, style="shade", title="Beta(x,y)", var1Steps==40, var2Steps==40)}
This is the Bessel function $J_\alpha (x)$ for index $\alpha$ in the range $-6..4$ and argument $x$ in the range $2..14$.

This is the modified Bessel function $I_\alpha (x)$ evaluated for various real values of the index $\alpha$ and fixed argument $x = 5$.

This is similar to the last example except the index takes on complex values in a $6 \times 6$ rectangle centered on the origin.

\texttt{(8) \ 2 2 2 2 2 2}
\texttt{(x - 3bb x + 3bb)(x + 3bb)(x + 3bb x + 3bb)}

\text{Type: Factored Polynomial AlgebraicNumber}

\spad{\text{\texttt{factor(x**6+108,\[bb\])}}\free{bb}}

\spad{\text{\texttt{factor(x**6+108,\[aa,bb\])}}\free{aa bb}}

\texttt{(9) \ (x + (- 2aa - 1)bb)(x + (- aa - 2)bb)}

\texttt{*}
\texttt{(x + (- aa + 1)bb)(x + (aa - 1)bb)(x + (aa + 2)bb)}

\texttt{*}
Factoring Rational Functions

Since fractions of polynomials form a field, every element (other than zero) divides any other, so there is no useful notion of irreducible factors. Thus the \texttt{factor} operation is not very useful for fractions of polynomials.

\begin{verbatim}
\spad{factor(x**6+108,[aa,bb])}
\end{verbatim}

\texttt{factorFraction} separates the numerator and denominator and returns a fraction of the factored results.

\begin{verbatim}
\spad{factorFraction((x**2-4)/(y**2-4))}
\end{verbatim}

You can also use \texttt{map}. This expression applies the \texttt{factor} operation to the numerator and denominator.

\begin{verbatim}
\spad{map(factor,(x**2-4)/(y**2-4))}
\end{verbatim}
Manipulating Symbolic Roots of a Polynomial

— ug08.ht —

{8.3. Manipulating Symbolic Roots of a Polynomial}
In this section we show you how to work with one root or all roots of a polynomial. These roots are represented symbolically (as opposed to being numeric approximations). See \downlink{``Solution of a Single Polynomial Equation''} in Section 8.5.2\ignore{ugxProblemOnePol} and \downlink{``Solution of Systems of Polynomial Equations''} in Section 8.5.3\ignore{ugxProblemPolSys} for information about solving for the roots of one or more polynomials.

\beginmenu
\menudownlink{{8.3.1. Using a Single Root of a Polynomial}}\ignore{ugxProblemSymRootOne}
\menudownlink{{8.3.2. Using All Roots of a Polynomial}}\ignore{ugxProblemSymRootAll}
\endmenu

Using a Single Root of a Polynomial

--- ug08.ht ---

Use \axiomFun{rootOf} to get a symbolic root of a polynomial: \axiom{rootOf(p, x)} returns a root of \axiom{p(x)}.

\labelSpace{2pc}
\xtc{
This creates an algebraic number \axiom{a}.
}{
\spadpaste{a := rootOf(a**4+1,a) \bound{a}}}
\xtc{
To find the algebraic relation that defines \axiom{a}, use \axiomFun{definingPolynomial}.}
You can use \axiom{a} in any further expression, including a nested \axiomFun{rootOf}.

}\{\spadpaste{b := rootOf(b**2-a-1,b) \free{a}\bound{b}}\}
\xtc{Higher powers of the roots are automatically reduced during calculations.}\{\spadpaste{a + b \free{a b}\bound{c}}\}
\xtc{The operation \axiomFun{zeroOf} is similar to \axiomFun{rootOf}, except that it may express the root using radicals in some cases.}\{\spadpaste{rootOf(c**2+c+1,c)}\}
\xtc{\spadpaste{zeroOf(d**2+d+1,d)}\}
\xtc{\spadpaste{rootOf(e**5-2,e)}\}
\xtc{\spadpaste{zeroOf(f**5-2,f)}\}

\indentrel{-3}(-3)
Using All Roots of a Polynomial
8.3.2. Using All Roots of a Polynomial

Use \axiomFun{rootsOf} to get all symbolic roots of a polynomial: \axiom{rootsOf(p, x)} returns a list of all the roots of \axiom{p(x)}. If \axiom{p(x)} has a multiple root of order \axiom{n}, then that root appears \axiom{n} times in the list.\typeout{Make sure these variables are x0 etc}{}

\begin{Schunk}
\begin{Sinput}
l := \axiom{rootsOf(x**4+1, x)} \free{l}
\end{Sinput}
\end{Schunk}

As a side effect, the variables \axiom{\%x0}, \axiom{\%x1} and \axiom{\%x2} are bound to the first three roots of \axiom{x**4+1}.

\begin{Schunk}
\begin{Sinput}
\axiom{\%x0**5} \free{l}
\end{Sinput}
\end{Schunk}

Although they all satisfy \axiom{x**4 + 1 = 0}, \axiom{\%x0, \%x1,} and \axiom{\%x2} are different algebraic numbers. To find the algebraic relation that defines each of them, use \axiomFun{definingPolynomial}.

\begin{Schunk}
\begin{Sinput}
\axiom{definingPolynomial \%x0} \free{l}
\end{Sinput}
\end{Schunk}

\begin{Schunk}
\begin{Sinput}
\axiom{definingPolynomial \%x1} \free{l}
\end{Sinput}
\end{Schunk}

\begin{Schunk}
\begin{Sinput}
\axiom{definingPolynomial \%x2} \free{l}
\end{Sinput}
\end{Schunk}

We can check that the sum and product of the roots of \axiom{x**4+1} are its trace and norm.

\begin{Schunk}
\begin{Sinput}
x3 := \axiom{last l} \free{x3}
\end{Sinput}
\end{Schunk}

\begin{Schunk}
\begin{Sinput}
\axiom{\%x0 + \%x1 + \%x2 + x3} \free{x3}
\end{Sinput}
\end{Schunk}
Corresponding to the pair of operations 
\axiomFun{rootOf}/\axiomFun{zeroOf} in 
\downlink{``Solution of a Single Polynomial Equation''} 
\ignore{ugxProblemOnePolPage} in Section 
8.5.2, there is an 
operation \axiomFun{zerosOf} that, like \axiomFun{rootsOf}, computes 
all the roots of a given polynomial, but which expresses some of them 
in terms of radicals.

As you see, only one implicit algebraic number was created 
(\axiom{\%y1}), and its defining equation is this. 
The other three roots are expressed in radicals.

As you see, only one implicit algebraic number was created

Computation of Eigenvalues and Eigenvectors

Let’s first create a matrix with integer entries.

\[
\begin{pmatrix}
1 & 2 & 1 \\
2 & 1 & -2 \\
1 & -2 & 4
\end{pmatrix}
\]

To get a list of the \textit{rational} eigenvalues, use the operation \texttt{eigenvalues}.

\[
\texttt{eigenvector(first(leig),m1)}
\]

The operation \texttt{eigenvectors} returns a list of pairs of values and vectors. When an eigenvalue is rational, Axiom gives you the value explicitly; otherwise, its minimal polynomial is given, (the polynomial of lowest degree with the eigenvalues as roots), together with a parametric representation of the eigenvector using the eigenvalue.

This means that if you ask Axiom to \texttt{solve} the minimal polynomial, then you can substitute these roots into the parametric form of the corresponding eigenvectors.

You must be aware that unless an exact eigenvalue has been computed, the eigenvector may be badly in error.
Another possibility is to use the operation \texttt{radicalEigenvectors} to try to compute explicitly the eigenvectors in terms of radicals.

\spad{radicalEigenvectors(m1) \free{m1}}

Alternatively, Axiom can compute real or complex approximations to the eigenvectors and eigenvalues using the operations \texttt{realEigenvectors} or \texttt{complexEigenvectors}. They each take an additional argument \texttt{epsilon} to specify the "precision" required. In the real case, this means that each approximation will be within plus or minus \texttt{epsilon} of the actual result. In the complex case, this means that each approximation will be within plus or minus \texttt{epsilon} of the actual result in each of the real and imaginary parts.

\spad{realEigenvectors(m1,1/1000) \free{m1}}

If an \texttt{n} by \texttt{n} matrix has \texttt{n} distinct eigenvalues (and therefore \texttt{n} eigenvectors) the operation \texttt{eigenMatrix} gives you a matrix of the eigenvectors.

\spad{eigenMatrix(m1) \free{m1}}

\spad{m2 := matrix \([-5,-2],[18,7]\) \bound{m2}}

\spad{eigenMatrix(m2) \free{m2}}

If a symmetric matrix has a basis of orthonormal eigenvectors, then \texttt{orthonormalBasis} computes a list of these vectors.

\begin{page}{ugProblemLinPolEqnPage}
In this section we discuss the Axiom facilities for solving systems of linear equations, finding the roots of polynomials and solving systems of polynomial equations.

For a discussion of the solution of differential equations, see \downlink{``Solution of Differential Equations''}{ugProblemDEQPage} in Section 8.10\ignore{ugProblemDEQ}.

\end{page}

Solution of Systems of Linear Equations

\begin{page}{ugxProblemLinSysPage}
\{8.5.1. Solution of Systems of Linear Equations}\beginscroll
You can use the operation \axiomFun{solve} to solve systems of linear equations.

The operation \axiomFun{solve} takes two arguments, the list of equations and the list of the unknowns to be solved for. A system of linear equations need not have a unique solution.

\xtc{
To solve the linear system:
\begincenterline{\axiom{x + y + z = 8}}
\begincenterline{\axiom{3x - 2y + z = 0}}
\begincenterline{\axiom{x + 2y + 2z = 17}}
\endcenterline{evaluate this expression.}}
\spadpaste{solve([x+y+z=8,3*x-2*y+z=0,x+2*y+2*z=17],[x,y,z])}
Parameters are given as new variables starting with a percent sign and the variables are expressed in terms of the parameters. If the system has no solutions then the empty list is returned.

When you solve the linear system
\begin{align*}
    x + 2y + 3z &= 2 \\
    2x + 3y + 4z &= 3 \\
    3x + 4y + 5z &= 2
\end{align*}
with this expression you get a solution involving a parameter.
\begin{verbatim}
spadpaste{solve([x+2*y+3*z=2,2*x+3*y+4*z=2,3*x+4*y+5*z=2],[x,y,z])}
\end{verbatim}
The system can also be presented as a matrix and a vector. The matrix contains the coefficients of the linear equations and the vector contains the numbers appearing on the right-hand sides of the equations. You may input the matrix as a list of rows and the vector as a list of its elements.

To solve the system:
\begin{align*}
    x + y + z &= 8 \\
    3x - 2y + z &= 0 \\
    x + 2y + 2z &= 17
\end{align*}
in matrix form you would evaluate this expression.
\begin{verbatim}
spadpaste{solve([[1,1,1],[3,-2,1],[1,2,2]],[8,0,17])}
\end{verbatim}
The solutions are presented as a \paspatype{Record} with two components: the component \texttt{particular} contains a particular solution of the given system or the item \texttt{failed} if there are no solutions, the component \texttt{basis} contains a list of vectors that are a basis for the space of solutions of the corresponding homogeneous system. If the system of linear equations does not have a unique solution, then the \texttt{basis} component contains non-trivial vectors.

This happens when you solve the linear system
\begin{align*}
    x + 2y + 3z &= 2 \\
    2x + 3y + 4z &= 2
\end{align*}
\centerline{\axiom{3*x + 4*y + 5*z = 2}}

with this command.

\{ 
\spadpaste{solve([[1,2,3],[2,3,4],[3,4,5]],[2,2,2])} 
\}

All solutions of this system are obtained by adding the particular solution with a linear combination of the \texttt{basis} vectors.

When no solution exists then \texttt{"failed"} is returned as the \texttt{particular} component, as follows:

\xtc{
\spadpaste{solve([[1,2,3],[2,3,4],[3,4,5]],[2,2,2])}
}

When you want to solve a system of homogeneous equations (that is, a system where the numbers on the right-hand sides of the equations are all zero) in the matrix form you can omit the second argument and use the \texttt{nullSpace} operation.

\xtc{
This computes the solutions of the following system of equations:
\centerline{\axiom{ x + 2*y + 3*z = 0 }}
\centerline{\axiom{2*x + 3*y + 4*z = 0 }}
\centerline{\axiom{3*x + 4*y + 5*z = 0}}

The result is given as a list of vectors and these vectors form a basis for the solution space.
}

\{ 
\spadpaste{nullSpace([[1,2,3],[2,3,4],[3,4,5]])} 
\}

\endscroll
\autobuttons
\end{page}
\spadcommand{solve([x+y+z=8,3*x-2*y+z=0,x+2*y+2*z=17],[x,y,z])}

\spadcommand{solve([x+2*y+3*z=2,2*x+3*y+4*z=2,3*x+4*y+5*z=2],[x,y,z])}

\verbatim
(2) \[\begin{array}{c}
x = \%Y - 2 \\
y = -2\%Y + 2 \\
z = \%Y
\end{array}\]
\end{verbatim}

\spadcommand{solve([[1,1,1],[3,-2,1],[1,2,2]],[8,0,17])}

\verbatim

\verbatim
(4) \{\text{particular} = \{-2,2,0\}, \text{basis} = \{1,-2,1\}\}
\end{verbatim}

\spadcommand{solve([[1,2,3],[2,3,4],[3,4,5]],[2,2,2])}
Solution of a Single Polynomial Equation

--- ug08.ht ---

Axiom can solve polynomial equations producing either approximate or exact solutions. Exact solutions are either members of the ground field or can be presented symbolically as roots of irreducible
polynomials.

This returns the one rational root along with an irreducible polynomial describing the other solutions.

\texttt{solve(x**3 = 8,x)}

If you want solutions expressed in terms of radicals you would use this instead.

\texttt{radicalSolve(x**3 = 8,x)}

The \texttt{solve} command always returns a value but \texttt{radicalSolve} returns only the solutions that it is able to express in terms of radicals.

If the polynomial equation has rational coefficients you can ask for approximations to its real roots by calling \texttt{solve} with a second argument that specifies the ‘precision’ \texttt{$\epsilon$}.

This means that each approximation will be within \texttt{$\pm \epsilon$} of the actual result.

Notice that the type of second argument controls the type of the result.

\texttt{solve(x**4 - 10*x**3 + 35*x**2 - 50*x + 25,.0001)}

If you give a floating-point precision you get a floating-point result; if you give the precision as a rational number you get a rational result.

\texttt{solve(x**3-2,1/1000)}

If you want approximate complex results you should use the command \texttt{complexSolve} that takes the same precision argument \texttt{$\epsilon$}.

\texttt{complexSolve(x**3-2,.0001)}

Each approximation will be within \texttt{$\pm \epsilon$} of the actual result in each of the real and imaginary parts.
\spadpaste{complexSolve(x**2-2*\%i+1,1/100)}

Note that if you omit the \axiomOp{=} from the first argument
Axiom generates an equation by equating the first argument to zero.
Also, when only one variable is present in the equation, you
do not need to specify the variable to be solved for, that is,
you can omit the second argument.

\xtc{
Axiom can also solve equations involving rational functions.
Solutions where the denominator vanishes are discarded.
}
\spadpaste{radicalSolve(1/x**3 + 1/x**2 + 1/x = 0,x)}

Solution of Systems of Polynomial Equations

Given a system of equations of rational functions with exact coefficients:
\[
\begin{align*}
\text{axiom}\{p1(x1,\ldots,xn)\} \\
\text{axiom}\{} \\
\text{axiom}\{\} \\
\text{axiom}\{\} \\
\text{axiom}\{pm(x1,\ldots,xn)\}
\end{align*}
\]
Axiom can find numeric or symbolic solutions.

The system is first split into irreducible components, then for each component, a triangular system of equations is found that reduces the problem to sequential solution of univariate polynomials resulting from substitution of partial solutions from the previous stage.

\[
\begin{align*}
\text{axiom}\{q1(x1,\ldots,xn)\} \\
\text{axiom}\{} \\
\text{axiom}\{\} \\
\text{axiom}\{\} \\
\text{axiom}\{qm(xn)\}
\end{align*}
\]

Symbolic solutions can be presented using "implicit" algebraic numbers defined as roots of irreducible polynomials or in terms of radicals.

Axiom can also find approximations to the real or complex roots of a system of polynomial equations to any user-specified accuracy.

The operation \texttt{\texttt{axiomFun}}(\texttt{solve}) for systems is used in a way similar to \texttt{\texttt{axiomFun}}(\texttt{solve}) for single equations.

Instead of a polynomial equation, one has to give a list of equations and instead of a single variable to solve for, a list of variables.

For solutions of single equations see \texttt{\texttt{\downlink{``Solution of a Single Polynomial Equation''}}}{\textit{ugxProblemOnePolPage}} in Section 8.5.2.

% 
\xtc{ 
Use the operation \texttt{\texttt{axiomFun}}(\texttt{solve}) if you want implicitly presented solutions. } 
\spadpaste{solve([3*x**3 + y + 1,y**2 -4],[x,y])}
} 
\xtc{ 
...
\spadpaste{solve([x = y**2-19,y = z**2+x+3,z = 3*x],[x,y,z])}

\xtc{
Use \axiomFun{radicalSolve} if you want your solutions expressed in terms of radicals.
}
\spadpaste{radicalSolve([3*x**3 + y + 1,y**2 -4],[x,y])}

To get numeric solutions you only need to give the list of equations and the precision desired. The list of variables would be redundant information since there can be no parameters for the numerical solver.

\xtc{
If the precision is expressed as a floating-point number you get results expressed as floats.
}
\spadpaste{solve([x**2*y - 1,x*y**2 - 2],.01)}

\xtc{
To get complex numeric solutions, use the operation \axiomFun{complexSolve}, which takes the same arguments as in the real case.
}
\spadpaste{complexSolve([x**2*y - 1,x*y**2 - 2],1/1000)}

\xtc{
It is also possible to solve systems of equations in rational functions over the rational numbers. Note that \axiom{[x = 0.0, a = 0.0]} is not returned as a solution since the denominator vanishes there.
}
\spadpaste{solve([x**2/a = a,a = a*x],.001)}

\xtc{
When solving equations with denominators, all solutions where the denominator vanishes are discarded.
}
\spadpaste{radicalSolve([x**2/a + a + y**3 - 1,a*y + a + 1],[x,y])}

To compute a limit, you must specify a functional expression, a variable, and a limiting value for that variable. If you do not specify a direction, Axiom attempts to compute a two-sided limit.

\begin{verbatim}
\spadcommand{radicalSolve([x**2/a + a + y**3 - 1,a*y + a + 1],[x,y])}
\end{verbatim}

\texttt{radicalSolve([x**2/a + a + y**3 - 1,a*y + a + 1],[x,y])}

Sometimes the limit when approached from the left is different from the limit from the right and, in this case, you may wish to ask for a one-sided limit. Also, if you have a function that is only defined on one side of a particular value, you can compute a one-sided limit.

\begin{verbatim}
\spadpaste{limit((x**2 - 3*x + 2)/(x**2 - 1),x = 1)}
\end{verbatim}

\texttt{limit((x**2 - 3*x + 2)/(x**2 - 1),x = 1)}

The function \axiom{log(x)} is only defined to the right of zero, that is, for \axiom{x > 0}. Thus, when computing limits of functions involving \axiom{log(x)}, you probably want a ‘‘right-hand’’ limit.
A function can be defined on both sides of a particular value, but tend to different limits as its variable approaches that value from the left and from the right.

We can construct an example of this as follows:

Since \( \sqrt{y^2} \) is simply the absolute value of \( y \), the function \( \sqrt{y^2} / y \) is simply the sign (either \(+1\) or \(-1\)) of the nonzero real number \( y \).

Therefore, \( \sqrt{y^2} / y = -1 \) for \( y < 0 \) and \( \sqrt{y^2} / y = +1 \) for \( y > 0 \).

This is what happens when we take the limit at \( y = 0 \). The answer returned by Axiom gives both a 'left-hand' and a 'right-hand' limit.

You can compute limits at infinity by passing either '+\infty' or '-\infty' as the third argument of \axiomFun{limit}.

To do this, use the constants \axiom{%plusInfinity} and \axiom{%minusInfinity}.

You can take limits of functions with parameters. As you can see, the limit is expressed in terms of the parameters.

\[ \lim_{x \to \%\text{minusInfinity}} \sqrt{3x^2 + 1} / (5x) \]

When you use \texttt{limit}, you are taking the limit of a real function of a real variable.

\[ \lim_{x \to 0} \frac{\sinh(ax)}{\tan(bx)} \]

When you compute this, Axiom returns \texttt{0} because, as a function of a real variable, \texttt{\sin(1/z)} is always between \texttt{-1} and \texttt{1}, so \texttt{\sin(1/z)} tends to \texttt{0} as \texttt{\sin(z)} tends to \texttt{0}.

\[ \lim_{z \to 0} z \cdot \sin(1/z) \]

However, as a function of a \texttt{complex} variable, \texttt{\sin(1/z)} is badly behaved near \texttt{0} (one says that \texttt{\sin(1/z)} has an \texttt{essential singularity} at \texttt{z = 0}).

When viewed as a function of a complex variable, \texttt{\sin(z) \cdot \sin(1/z)} does not approach any limit as \texttt{\sin(z)} tends to \texttt{0} in the complex plane. Axiom indicates this when we call \texttt{complexLimit}.

\[ \lim_{z \to \%\text{infinity}} \frac{2 + z}{1 - z} \]

You can also take complex limits at infinity, that is, limits of a function of \texttt{z} as \texttt{z} approaches infinity on the Riemann sphere. Use the symbol \texttt{\%infinity} to denote \texttt{complex infinity}.

As above, to compute complex limits rather than real limits, use \texttt{complexLimit}.

\[ \lim_{x \to \%\text{plusInfinity}} \sin(x) / x \]

In many cases, a limit of a real function of a real variable exists when the corresponding complex limit does not. This limit exists.
But this limit does not.

\spadpaste{complexLimit(sin(x)/x,x = \%infinity)}

Laplace Transforms

--- ug08.ht ---

Axiom can compute some forward Laplace transforms, mostly of elementary functions not involving logarithms, although some cases of special functions are handled.
To compute the forward Laplace transform of $F(t)$ with respect to $t$ and express the result as $f(s)$, issue the command 
\axiom{laplace(F(t), t, s)}.

}\spadpaste{laplace(sin(a*t)*cosh(a*t)-cos(a*t)*sinh(a*t), t, s)}
\xtc{
Here are some other non-trivial examples.
}\spadpaste{laplace((exp(a*t) - exp(b*t))/t, t, s)}
\xtc{
}\spadpaste{laplace(2/t * (1 - cos(a*t)), t, s)}
\xtc{
}\spadpaste{laplace(exp(-a*t) * sin(b*t) / b**2, t, s)}
\xtc{
}\spadpaste{laplace((cos(a*t) - cos(b*t))/t, t, s)}

Axiom also knows about a few special functions.
}\spadpaste{laplace(exp(a*t+b)*Ei(c*t), t, s)}
\xtc{
}\spadpaste{laplace(a*Ci(b*t) + c*Si(d*t), t, s)}
\xtc{
When Axiom does not know about a particular transform, it keeps it as a formal transform in the answer.

Integration

Integration is the reverse process of differentiation, that is, an integral of a function \( f \) with respect to a variable \( x \) is any function \( g \) such that \( D(g,x) \) is equal to \( f \).

The package \texttt{FunctionSpaceIntegration} provides the top-level integration operation, \texttt{FunctionSpaceIntegration\{integrate\}}, for integrating real-valued elementary functions.

\[
\text{integrate(} \cosh(ax) \cdot \sinh(ax), \ x) \text{)}
\]

Unfortunately, antiderivatives of most functions cannot be expressed in terms of elementary functions.

\[
\text{integrate(} \log(1 + \sqrt{ax + b}) / x, \ x) \text{)}
\]

Given an elementary function to integrate, Axiom returns a formal integral as above only when it can prove that the integral is not elementary and not when it cannot determine the integral. In this rare case it prints a message that it cannot determine if an elementary integral exists.

Similar functions may have antiderivatives that look quite different because the form of the antiderivative depends on the sign of a constant that appears in the function.

\[
\text{integrate(} 1/(x^2 - 2), \ x) \text{)}
\]

\[
\text{integrate(} 1/(x^2 + 2), \ x) \text{)}
\]

If the integrand contains parameters, then there may be several possible antiderivatives, depending on the signs of expressions of the parameters.

In this case Axiom returns a list of answers that cover all the possible cases.

Here you
use the answer involving the square root of \( \text{axiom\{a\}} \) when \( \text{axiom\{a > 0\}} \) and
the answer involving the square root of \( \text{axiom\{-a\}} \) when \( \text{axiom\{a < 0\}} \).

\[
\text{\spadpaste{integrate(x**2 / (x**4 - a**2), x)}}
\]

If the parameters and the variables of integration can be complex
numbers rather than real, then the notion of sign is not defined.
In this case all the possible answers can be expressed as one
complex function.
To get that function, rather than a list of real functions, use
\axiomFunFrom{complexIntegrate}{FunctionSpaceComplexIntegration},
which is provided by the package
\axiomType{FunctionSpaceComplexIntegration}.

\[
\text{\spadpaste{complexIntegrate(x**2 / (x**4 - a**2), x)}}
\]

As with the real case,
antiderivatives for most complex-valued functions cannot be expressed
in terms of elementary functions.

\[
\text{\spadpaste{complexIntegrate(log(1 + sqrt(a * x + b)) / x, x)}}
\]

Sometimes \axiomFun{integrate} can involve symbolic algebraic numbers
such as those returned by \axiomFunFrom{rootOf}{Expression}.
To see how to work with these strange generated symbols (such as
\axiom{\%\%a0}), see
\downlink{``Using All Roots of a Polynomial''}{ugxProblemSymRootAllPage} in Section 8.3.2\ignore{ugxProblemSymRootAll}.

Definite integration is the process of computing the area between the
\axiom{x}-axis and the curve of a function \axiom{f(x)}. The
fundamental theorem of calculus states that if \axiom{f} is continuous
on an interval \axiom{a..b} and if there exists a function \axiom{g}
that is differentiable on \axiom{a..b} and such that \axiom{D(g, x)}
is equal to \axiom{f}, then the definite integral of \axiom{f} for
\axiom{x} in the interval \axiom{a..b} is equal to \axiom{g(b) - g(a)}.

\[
\text{\spadpaste{RationalFunctionDefiniteIntegration}}
\]

The package \axiomType{RationalFunctionDefiniteIntegration} provides
the top-level definite integration operation,
\axiomFunFrom{integrate}{RationalFunctionDefiniteIntegration},
for integrating real-valued rational functions.
Axiom checks beforehand that the function you are integrating is defined on the interval \( \text{a..b} \), and prints an error message if it finds that this is not case, as in the following example:

\begin{verbatim}
integrate(1/(x**2-2), x = 1..2)
\end{verbatim}

>> Error detected within library code:
  Pole in path of integration
  You are being returned to the top level
  of the interpreter.
\end{verbatim}

When parameters are present in the function, the function may or may not be defined on the interval of integration.

\xtc{
If this is the case, Axiom issues a warning that a pole might lie in the path of integration, and does not compute the integral.
}\}

\begin{verbatim}
integrate(1/(x**2-a), x = 1..2)
\end{verbatim}

If you know that you are using values of the parameter for which the function has no pole in the interval of integration, use the string \tt "noPole" as a third argument to \axiomFunFrom{integrate}{RationalFunctionDefiniteIntegration}:

\xtc{
The value here is, of course, incorrect if \axiom{sqrt(a)} is between \axiom{1} and \axiom{2.}
}\}

\begin{verbatim}
integrate(1/(x**2-a), x = 1..2, "noPole")
\end{verbatim}

\begin{page}{ugProblemSeriesPage}{8.9. Working with Power Series}
Axiom has very sophisticated facilities for working with power series. Infinite series are represented by a list of the coefficients that have already been determined, together with a function for computing the additional coefficients if needed. The system command that determines how many terms of a series is displayed is `\spadcmd{)set streams calculate}`. For the purposes of this book, we have used this system command to display fewer than ten terms. Series can be created from expressions, from functions for the series coefficients, and from applications of operations on existing series. The most general function for creating a series is called `\axiomFun{series}`, although you can also use `\axiomFun{taylor}`, `\axiomFun{laurent}` and `\axiomFun{puiseux}` in situations where you know what kind of exponents are involved.

For information about solving differential equations in terms of power series, see `\ugxProblemDEQSeriesPage` in Section 8.10.3. For information about solving differential equations in terms of power series, see `\ugxProblemDEQSeriesPage` in Section 8.10.3.
Creation of Power Series

This is the easiest way to create a power series. This tells Axiom that \texttt{x} is to be treated as a power series, so functions of \texttt{x} are again power series.

\begin{spad}{x := \text{series } x \text{ \texttt{bound}(x)}}
\end{spad}

We didn't say anything about the coefficients of the power series, so the coefficients are general expressions over the integers. This allows us to introduce denominators, symbolic constants, and other variables as needed.

\begin{spad}{1/(1 - x - x**2) \texttt{free}(x)}
\end{spad}

This series has coefficients that are rational numbers.

\begin{spad}{\sin(x) \texttt{free}(x)}
\end{spad}

When you enter this expression you introduce the symbolic constants \texttt{\text{axiom(sin(1))}} and \texttt{\text{axiom(cos(1))}}.

\begin{spad}{\sin(1 + x) \texttt{free}(x)}
\end{spad}

When you enter the expression the variable \texttt{\text{axiom(a)}} appears in the resulting series expansion.

\begin{spad}{\sin(a * x) \texttt{free}(x)}
\end{spad}
You can also convert an expression into a series expansion. This expression creates the series expansion of \(\text{axiom}(1/\log(y))\) about \(\text{axiom}(y = 1)\). For details and more examples, see \downlink{``Converting to Power Series''}{ugxProblemSeriesConversionsPage} in Section 8.9.5\ignore{ugxProblemSeriesConversions}.

\spadpaste{\text{series}(1/\log(y), y = 1)}

You can create power series with more general coefficients. You normally accomplish this via a type declaration (see \downlink{``Declarations''}{ugTypesDeclarePage} in Section 2.3\ignore{ugTypesDeclare}). See \downlink{``Functions on Power Series''}{ugxProblemSeriesFunctionsPage} in Section 8.9.4\ignore{ugxProblemSeriesFunctions} for some warnings about working with declared series.

We declare that \(\text{axiom}(y)\) is a one-variable Taylor series \(\text{axiomType}(\text{UTS})\) is the abbreviation for \(\text{axiomType}(\text{UnivariateTaylorSeries})\) in the variable \(\text{axiom}(z)\) with \(\text{axiomType}(\text{FLOAT})\) (that is, floating-point) coefficients, centered about \(\text{axiom}(0)\). Then, by assignment, we obtain the Taylor expansion of \(\text{axiom}(\exp(z))\) with floating-point coefficients.

\spadpaste{y : \text{UTS}(\text{FLOAT}, 'z, 0) := \exp(z) \text{ bound}(y)}

You can also create a power series by giving an explicit formula for its \(\text{axiom}(n)\) coefficient. For details and more examples, see \downlink{``Power Series from Formulas''}{ugxProblemSeriesFormulaPage} in Section 8.9.6\ignore{ugxProblemSeriesFormula}.

To create a series about \(\text{axiom}(w = 0)\) whose \(\text{axiom}(n)\) Taylor coefficient is \(\text{axiom}(1/n!)\), you can evaluate this expression. This is the Taylor expansion of \(\text{axiom}(\exp(w))\) at \(\text{axiom}(w = 0)\).

\spadpaste{\text{series}(1/\text{factorial}(n), n, w = 0)}

Coefficients of Power Series

You can extract any coefficient from a power series---even one that hasn't been computed yet. This is possible because in Axiom, infinite series are represented by a list of the coefficients that have already been determined, together with a function for computing the additional coefficients. (This is known as \textit{lazy evaluation}.) When you ask for a coefficient that hasn't yet been computed, Axiom computes whatever additional coefficients it needs and then stores them in the representation of the power series.

Here's an example of how to extract the coefficients of a power series.

\begin{spadexample}
\spad{\text{Here's an example of how to extract the coefficients of a power series.}}
\end{spadexample}

\begin{spadexample}
\spad{\text{This coefficient is readily available.}}
\end{spadexample}

\begin{spadexample}
\spad{\text{But let's get the fifteenth coefficient of \axiom{y}.}}
\end{spadexample}
If you look at \axiom{y} then you see that the coefficients up to order \axiom{15} have all been computed.

Functions on Power Series

--- ug08.ht ---

Once you have created a power series, you can apply transcendental functions (for example, \axiomFun{exp}, \axiomFun{log}, \axiomFun{sin}, \axiomFun{tan}, \axiomFun{cosh}, etc.) to it.

\labelSpace{1pc}
\%
\xtc{}
To demonstrate this, we first create the power series expansion of the rational function
\texht{$x^2$ \over $1 - 6x + x^2$}
\begin{axiom}
x**2/(1 - 6*x + x**2)
\end{axiom}
about \begin{axiom}x = 0\end{axiom}.
\begin{spadpaste}
x := series 'x \bound{x}
\end{spadpaste}
\begin{spadpaste}
rat := x**2 / (1 - 6*x + x**2) \free{x} \bound{rat}
\end{spadpaste}
\begin{xtc}
If you want to compute the series expansion of
\begin{texht}
\sin\left(\frac{x^2}{1 - 6x + x^2}\right)
\end{texht}
\begin{axiom}
sin(x**2/(1 - 6*x + x**2))
\end{axiom}
you simply compute the sine of \begin{axiom}rat\end{axiom}.
\begin{spadpaste}
sin(rat) \free{rat}
\end{spadpaste}
\begin{Important}
\noindent \textbf{Warning:}
the type of the coefficients of a power series may
affect the kind of computations that you can do with that series.
This can only happen when you have made a declaration to
specify a series domain with a certain type of coefficient.
\end{Important}
\begin{xtc}
If you evaluate
then you have declared that \begin{axiom}y\end{axiom} is a one variable Taylor series
\begin{axiomType}(UTS)\end{axiomType} is the abbreviation for \begin{axiomType}(UnivariateTaylorSeries)\end{axiomType}
in the variable \begin{axiom}y\end{axiom} with \begin{axiomType}(FRAC INT)\end{axiomType}
(that is, fractions of integer) coefficients, centered about \begin{axiom}0\end{axiom}.
\begin{spadpaste}
y : UTS(FRAC INT,y,0) := y \bound{y}
\end{spadpaste}
\begin{xtc}
You can now compute certain power series in \begin{axiom}y\end{axiom},
\begin{it}(it provided)\end{it} that these series have rational coefficients.
\begin{spadpaste}
exp(y) \free{y}
\end{spadpaste}
You can get examples of such series by applying transcendental functions to series in \axiom{y} that have no constant terms.

\begin{verbatim}
\spadpaste{tan(y**2) \free{y}}
\end{verbatim}

\begin{verbatim}
\spadpaste{cos(y + y**5) \free{y}}
\end{verbatim}

Similarly, you can compute the logarithm of a power series with rational coefficients if the constant coefficient is \axiom{1}.

\begin{verbatim}
\spadpaste{log(1 + sin(y)) \free{y}}
\end{verbatim}

If you wanted to apply, say, the operation \axiomFun{exp} to a power series with a nonzero constant coefficient \texttt{$a_0$}, then the constant coefficient of the result would be \texttt{$e^{a_0}$}, which is \texttt{not} a rational number. Therefore, evaluating \axiom{exp(2 + tan(y))} would generate an error message.

If you want to compute the Taylor expansion of \axiom{exp(2 + tan(y))}, you must ensure that the coefficient domain has an operation \axiomFun{exp} defined for it. An example of such a domain is \axiomType{Expression Integer}, the type of formal functional expressions over the integers.

\begin{verbatim}
\spadpaste{z : UTS(EXPR INT,z,0) := z \bound{z}}
\end{verbatim}

When working with coefficients of this type,

\begin{verbatim}
\spadpaste{exp(2 + tan(z)) \free{z}}
\end{verbatim}

Another way to create Taylor series whose coefficients are expressions over the integers is to use \axiomFun{taylor} which works similarly to \axiomFun{series}.
This is equivalent to the previous computation, except that now we are using the variable \texttt{w} instead of \texttt{z}.

\spad{w := taylor \ 'w \ \text{bound}(w)} \}
\spad{exp(2 + \text{tan}(w)) \ \text{free}(w)} \}

Converting to Power Series

--- ug08.ht ---

The \axiomType{ExpressionToUnivariatePowerSeries} package provides operations for computing series expansions of functions.

Evaluate this to compute the Taylor expansion of \axiom{\sin x} about \axiom{x = 0}.

The first argument, \axiom{\sin(x)}, specifies the function whose series expansion is to be computed and the second argument, \axiom{x = 0},
specifies that the series is to be expanded in power of \(x - 0\),
that is, in power of \(x\).
}\{ 
\spad{\text{taylor}(\sin(x), x = 0)}
\}
\xtc{Here is the Taylor expansion of \(\sin x\) about \(x = \frac{\pi}{6}\):} 
\{ 
\spad{\text{taylor}(\sin(x), x = \%pi/6)}
\}

The function to be expanded into a series may have variables other than
the series variable.
% 
\xtc{For example, we may expand \(\tan(x y)\) as a Taylor series in
\(x\)} 
\{ 
\spad{\text{taylor}(\tan(x y), x = 0)}
\}
% 
\xtc{or as a Taylor series in \(y\).} 
\{ 
\spad{\text{taylor}(\tan(x y), y = 0)}
\}
\xtc{A more interesting function is}
\xtc{\(\frac{t e^{x t}}{e^t - 1}\).} 
\{ 
\spad{\text{bern} := \text{taylor}(t*\exp(x*t)/(\exp(t) - 1), t = 0) \ bound{bern}}
\}
\xtc{Therefore, this and the next expression
produce the same result.} 
\{ 
\spad{\text{factorial}(6) * \text{coefficient}(\text{bern},6) \ free{bern}}
\}
\xtc{\}
\spad{\text{bernoulliB}(6,x)}
\}

Technically, a series with terms of negative degree is not considered to
be a Taylor series, but, rather, a

\textit{Laurent series}.

If you try to compute a Taylor series expansion of

\[ \frac{x}{\log x} \]

at \texttt{x = 1} via \texttt{taylor(x/log(x),x = 1)}
you get an error message.

The reason is that the function has a \textit{pole} at \texttt{x = 1}, meaning that
its series expansion about this point has terms of negative degree.

A series with finitely many terms of negative degree is called a Laurent
series.

\xtc{}
You get the desired series expansion by issuing this.
}

\spadpaste{laurent(x/log(x),x = 1)}

Similarly, a series with terms of fractional degree is neither a

Taylor series nor a Laurent series. Such a series is called a \textit{Puiseux series}. The expression \texttt{laurent(sqrt(sec(x)),x = 3 * \%pi/2)} results in an error message because the series expansion
about this point has terms of fractional degree.

\xtc{}
However, this command produces what you want.
}

\spadpaste{puiseux(sqrt(sec(x)),x = 3 * \%pi/2)}

Finally, consider the case of functions that do not have Puiseux
expansions about certain points. An example of this is

\texttt{x**x\axiom{x = 0}}.

\texttt{puiseux(x**x,x=0)} produces an error message because of the
type of singularity of the function at \texttt{x = 0}.

\xtc{}
The general function \axiomFun{series} can be used in this case.

Notice that the series returned is not, strictly speaking, a power series
because of the \texttt{log(x)} in the expansion.
}

\spadpaste{series(x**x,x=0)}

The operation \axiomFun{series} returns the most general type of
infinite series.

The user who is not interested in distinguishing
between various types of infinite series may wish to use this operation
exclusively.

\end{patch}
The \axiomType{GenerateUnivariatePowerSeries} package enables you to create power series from explicit formulas for their \eth{\axiom{n}} coefficients. In what follows, we construct series expansions for certain transcendental functions by giving formulas for their coefficients. You can also compute such series expansions directly.
simply by specifying the function and the point about which the series
is to be expanded. See
\downlink{“Converting to Power Series”}
{ugxProblemSeriesConversionsPage} in Section
8.9.5\ignore{ugxProblemSeriesConversions}
for more information.

Consider the Taylor expansion of $e^x$ about $x = 0$:
\[
\begin{align*}
e^x &= 1 + x + \frac{x^2}{2} + \frac{x^3}{6} + \cdots \\
&= \sum_{n=0}^{\infty} \frac{x^n}{n!}
\end{align*}
\]

The $n$th Taylor coefficient is $\frac{1}{n!}$.

This is how you create this series in Axiom.

\spadpaste{series(n +-> 1/factorial(n),x = 0)}

The first argument specifies a formula for the $n$th coefficient by giving a function that maps $n$ to $\frac{1}{n!}$. The second argument specifies that the series is to be expanded in powers of $(x - 0)$, that is, in powers of $x$. Since we did not specify an initial degree, the first term in the series was the term of degree 0 (the constant term). Note that the formula was given as an anonymous function. These are discussed in
\downlink{“Anonymous Functions”}
{ugUserAnonPage} in Section
6.17\ignore{ugUserAnon}.

Consider the Taylor expansion of $\log x$ about $x = 1$:
\[
\begin{align*}
\log(x) &= (x - 1) - \frac{(x - 1)^2}{2} + \frac{(x - 1)^3}{3} - \cdots \\
&= \sum_{n = 1}^{\infty} (-1)^{n-1} \frac{(x - 1)^n}{n}
\end{align*}
\]

\spadpaste{series(n +-> (-1)**(n-1)/(n-1),x = 1)}
If you were to evaluate the expression
\axiom{series(n +-> (-1)**(n-1) / n, x = 1)}
you would get an error message because Axiom would try to
calculate a term of degree \axiom{0} and therefore divide by \axiom{0}.

Instead, evaluate this.

The third argument, \axiom{1..}, indicates that only terms of degree
\axiom{n = 1, ...} are to be computed.

The Taylor expansion of an odd function, say, \axiom{sin(x)}:
\begin{verbatim}
  sin x = x - x**3/3! + x**5/5! - ...
\end{verbatim}
Here every other coefficient is zero and we would like to give an
explicit formula only for the odd Taylor coefficients.

This is one way to do it. The third argument, \axiom{1..}, specifies
that the first term to be computed is the term of degree 1. The
fourth argument, \axiom{2}, specifies that we increment by \axiom{2}
to find the degrees of subsequent terms, that is, the next term is of
degree \axiom{1 + 2}, the next of degree \axiom{1 + 2 + 2}, etc.

The initial degree and the increment do not have to be integers.
For example, this expression produces a series expansion of
\texht{$\sin(x^{1/3})$}.

\begin{verbatim}
  \axiom{cscx := series(n +-> (-1)**((3*n-1)/2)/factorial(3*n), x=0, -1..,2)}
\end{verbatim}
While the increment must be positive, the initial degree may be negative.

This yields the Laurent expansion of \axiom{csc(x)} at
\axiom{x = 0}.

\begin{verbatim}
  \axiom{cscx := series(n +-> (-1)**(n-1)/n, x = 0, 1..,2) \bound{cscx}}
\end{verbatim}
Of course, the reciprocal of this power series is the Taylor expansion of \( \text{\texttt{sin(x)}} \).

\[
\frac{1}{\text{csc}x} \\text{\texttt{csc}}
\]

As a final example, here is the Taylor expansion of \( \text{\texttt{asin(x)}} \) about \( \text{\texttt{x = 0}} \).

\[
\text{\texttt{asinx := series(n +-> binomial(n-1,(n-1)/2)/(n*2**(n-1)), x=0,1..,2)}} \\text{\texttt{bound(asinx)}}
\]

When we compute the \( \text{\texttt{sin}} \) of this series, we get \( \text{\texttt{x}} \) (in the sense that all higher terms computed so far are zero).

As we discussed in \text{\texttt{Converting to Power Series}}\text{\texttt{ProblemSeriesConversionsPage}} in Section 8.9.5\text{\texttt{ProblemSeriesConversions}}, you can also use the operations \( \text{\texttt{taylor}}, \text{\texttt{laurent}} \) and \( \text{\texttt{puiseux}} \) instead of \( \text{\texttt{series}} \) if you know ahead of time what kind of exponents a series has. You can't go wrong using \( \text{\texttt{series}} \), though.

\[
\text{\texttt{series(n +-> 1/factorial(n),x = 0)}}
\]

\[
\begin{verbatim}
(1)
1 + x + x + x + x + x + x + x + x + x + x + x + O(x )

Substituting Numerical Values in Power Series

--- ug08.ht ---

Use $\text{eval}$ to substitute a numerical value for a variable in a power series. For example, here's a way to obtain numerical approximations of $\text{exp}(x)$ from the Taylor series expansion of $\text{exp}(x)$.

First you create the desired Taylor expansion.

```spad
f := taylor(exp(x)) \bound{f}
```

Then you evaluate the series at the value $1.0$. The result is a sequence of the partial sums.

```spad
eval(f,1.0)
```
\begin{verbatim}
(1)
  1  2  3  4  5  6
1 + x + x + x + x + x + x
  2   6  24  120  720
+

Example: Bernoulli Polynomials and Sums of Powers

Axiom provides operations for computing definite and indefinite sums.

You can compute the sum of the first ten fourth powers by evaluating this.
This creates a list whose entries are \(m^4\) as \(m\) ranges from 1 to 10, and then computes the sum of the entries of that list.

\[
\text{reduce}(+[m^4 \text{ for } m \text{ in } 1..10])
\]

You can also compute a formula for the sum of the first \(k\) fourth powers, where \(k\) is an unspecified positive integer.

\[
\text{sum4} := \text{sum}(m^4, m = 1..k) \text{ free } \text{sum4}
\]

This formula is valid for any positive integer \(k\). For instance, if we replace \(k\) by 10, we obtain the number we computed earlier.

\[
\text{eval}(\text{sum4}, k = 10) \text{ free } \text{sum4}
\]

You can compute a formula for the sum of the first \(k\) powers in a similar fashion. Just replace the \(4\) in the definition of \(\text{sum4}\) by any expression not involving \(k\). Axiom computes these formulas using Bernoulli polynomials; we use the rest of this section to describe this method.

First consider this function of \(t\) and \(x\).

\[
f := t*\exp(x*t) \text{ / (exp(t) - 1)} \text{ bound } f
\]
Since the expressions involved get quite large, we tell Axiom to show us only terms of degree up to \(5\).

\[\text{set streams calculate 5}\]

If we look at the Taylor expansion of \(f(x, t)\) about \(t = 0\), we see that the coefficients of the powers of \(t\) are polynomials in \(x\).

\[\text{set streams calculate 5}\]

In fact, the \(n\)th coefficient in this series is essentially the \(n\)th Bernoulli polynomial: the \(n\)th coefficient of the series is

\[\frac{1}{n!} B_n(x)\]

where \(B_n(x)\) is the \(n\)th Bernoulli polynomial. Thus, to obtain the \(n\)th Bernoulli polynomial, we multiply the \(n\)th coefficient of the series \(ff\) by \(n!\).

For example, the sixth Bernoulli polynomial is this.

\[\text{factorial(6) * coefficient(ff,6)}\]

We derive some properties of the function \(f(x,t)\). First we compute \(f(x + 1,t) - f(x,t)\).

\[\text{eval(f, x = x + 1) - f}\]

If we normalize \(g\), we see that it has a particularly simple form.

\[\text{normalize(g)}\]

From this it follows that the \(n\)th coefficient in the Taylor expansion of \(g(x,t)\) at \(t = 0\) is

\[\frac{1}{(n-1)!} x^{n-1}\]
If you want to check this, evaluate the next expression.
}\spadpaste{taylor(g,t = 0) \free{g}}
}

However, since \axiom{g(x,t) = f(x+1,t)-f(x,t)}, it follows that the
\eth{\axiom{n}} coefficient is
\\[ \frac{1}{n!} (B_n(x+1)-B_n(x)).\]
Equating coefficients, we see that
\\[ \frac{1}{(n-1)!} x^{n-1} = \frac{1}{n!} (B_n(x+1)-B_n(x)) \\]
and, therefore,
\\[ x^{n-1} = \frac{1}{n} (B_n(x+1)-B_n(x)).\]

Let’s apply this formula repeatedly, letting \axiom{x} vary between two
integers \axiom{a} and \axiom{b}, with \axiom{a < b}:
%\begin{verbatim}
\verbatimbegin{verbatim}
a**(n-1) = 1/n * (Bn(a + 1) - Bn(a))
(a + 1)**(n-1) = 1/n * (Bn(a + 2) - Bn(a + 1))
(a + 2)**(n-1) = 1/n * (Bn(a + 3) - Bn(a + 2))
. .
(b - 1)**(n-1) = 1/n * (Bn(b) - Bn(b - 1))
b**(n-1) = 1/n * (Bn(b + 1) - Bn(b))
\verbatimend{verbatim}
\verbatimend{verbatim}

When we add these equations we find that
the sum of the left-hand sides is
\\[ \sum_{m=a}^{b} m^{n-1}, \]
the sum of the
\( (n-1)^{\text{st}} \)
powers from \axiom{a} to \axiom{b}.
The sum of the right-hand sides is a ‘‘telescoping series.’’
After cancellation, the sum is simply
\\[ \frac{1}{n} (B_n(b + 1) - B_n(a)).\]
Replacing \axiom{n} by \axiom{n + 1}, we have shown that
\\[ \sum_{m=a}^{b} m^{n} = \frac{1}{n+1} * (B_{n+1}(b + 1) - B_{n+1}(a)).\]

Let’s use this to obtain the formula for the sum of fourth powers.
\xtc{
First we obtain the Bernoulli polynomial \axiom{B_5}.
}{
\spadpaste{B5 := factorial(5) * coefficient(ff,5) \free{ff} \bound{B5}}
To find the sum of the first $k$ 4th powers, we multiply $\frac{1}{5}$ by $B_5(k+1) - B_5(1)$. 

\[
\frac{1}{5} * \left( \text{eval}(B_5, x = k + 1) - \text{eval}(B_5, x = 1) \right)
\]

This is the same formula that we obtained via $\text{sum}(m^4, m = 1..k)$.

At this point you may want to do the same computation, but with an exponent other than 4.

For example, you might try to find a formula for the sum of the first $k$ 20th powers.

```
\begin{verbatim}
reduce(+,[m**20 for m in 1..10])
\end{verbatim}
```

Solution of Differential Equations

In this section we discuss Axiom's facilities for solving differential equations in closed-form and in series. Axiom provides facilities for closed-form solution of single differential equations of the following kinds:

- linear ordinary differential equations, and
- non-linear first order ordinary differential equations when integrating factors can be found just by integration.
For a discussion of the solution of systems of linear and polynomial
equations, see
\downlink{"Solution of Linear and Polynomial Equations"}
{ugProblemLinPolEqnPage} in Section 8.5\ignore{ugProblemLinPolEqn}.

\end{page}

Closed-Form Solutions of Linear Differential Equations

A \{it differential equation\} is an equation involving an unknown
\{it function\} and one or more of its derivatives. The equation is
called \{it ordinary\} if derivatives with respect to only one dependent
variable appear in the equation (it is called \{it partial\}
on otherwise). The package \axiomType{ElementaryFunctionODESolver}
provides the top-level operation \spadfun{solve} for finding
closed-form solutions of ordinary differential equations.

To solve a differential equation, you must first create an operator for
the unknown function.

\xtc{
We let \axiom{y} be the unknown function in terms of \axiom{x}.
}

\spadpaste{y := operator 'y \bound{y}}
You then type the equation using \axiomFun{D} to create the
derivatives of the unknown function \axiom{y(x)} where \axiom{x} is any
symbol you choose (the so-called \it{dependent variable}).
\%
\xtc{}
This is how you enter
the equation \axiom{y'' + y' + y = 0}.
\}\{\spadpaste{deq := D(y x, x, 2) + D(y x, x) + y x = 0\bound{e1}\free{y}}
\}
\%
The simplest way to invoke the \axiomFun{solve} command is with three
arguments.
\begin{itemize}
\item the differential equation,
\item the operator representing the unknown function,
\item the dependent variable.
\end{itemize}
\%
\xtc{}
So, to solve the above equation, we enter this.
\}{\spadpaste{solve(deq, y, x) \free{e1}\free{y}}}
\}
\%
Since linear ordinary differential equations have infinitely many
solutions, \axiomFun{solve} returns a \it{particular solution}
\axiom{f_p} and a basis
\axiom{f_1,\ldots,f_n} for the solutions of the corresponding homogenuous equation.
Any expression of the form
\axiom{f_p + c_1 f_1 + \ldots c_n f_n} where the \axiom{c_i} do not involve
the dependent variable is also a solution.
This is similar to what you get when you solve systems of linear
algebraic equations.

A way to select a unique solution is to specify \it{initial
conditions}: choose a value \axiom{a} for the dependent variable
and specify the values of the unknown function and its derivatives
at \axiom{a}.
If the number of initial conditions is equal to the order of the
equation, then the solution is unique (if it exists in closed
form!) and \axiomFun{solve} tries to find it.
To specify initial conditions to \axiomFun{solve}, use an
\axiomType{Equation} of the form \axiom{x = a} for the third
parameter instead of the dependent variable, and add a fourth
parameter consisting of the list of values \axiom{y(a), y'(a), \ldots}. 
To find the solution of \( y'' + y = 0 \) satisfying \( y(0) = y'(0) = 1 \), do this.

\[
\text{deq} := D(y \text{ x, x, 2}) + y \text{ x} \text{free(y)}
\]

You can omit the \( = 0 \) when you enter the equation to be solved.

\[
\text{solve(deq, y, x = 0, [1, 1]) \text{ free(y)}}
\]

Axiom is not limited to linear differential equations with constant coefficients. It can also find solutions when the coefficients are rational or algebraic functions of the dependent variable. Furthermore, Axiom is not limited by the order of the equation.

Axiom can solve the following third order equations with polynomial coefficients.

\[
\text{deq} := x**3 * D(y \text{ x, x, 3}) + x**2 * D(y \text{ x, x, 2}) - 2 * x * D(y \text{ x, x}) + 2 * y \text{ x} = 2 * x**4 \text{free(y)}
\]

Here we are solving a homogeneous equation.

\[
\text{deq} := (x**9+x**3) * D(y \text{ x, x, 3}) + 18 * x**8 * D(y \text{ x, x, 2}) - 90 * x * D(y \text{ x, x}) - 30 * (11 * x**6 - 3) * y \text{ x} \text{free(y)}
\]

On the other hand, and in contrast with the operation \( \text{axiomFun(integrate)} \), it can happen that Axiom finds no solution and that some closed-form solution still exists. While it is mathematically complicated to describe exactly when the solutions are guaranteed to be found, the following statements are correct and form good guidelines for linear ordinary differential equations:
\begin{items}
\item If the coefficients are constants, Axiom finds a complete basis of solutions (i.e., all solutions).
\item If the coefficients are rational functions in the dependent variable, Axiom at least finds all solutions that do not involve algebraic functions.
\end{items}

Note that this last statement does not mean that Axiom does not find the solutions that are algebraic functions. It means that it is not guaranteed that the algebraic function solutions will be found.

This is an example where all the algebraic solutions are found.

\spadpaste{deq := (x**2 + 1) * D(y x, x, 2) + 3 * x * D(y x, x) + y x = 0}

Closed-Form Solutions of Non-Linear DEs

This is an example that shows how to solve a non-linear first order ordinary differential equation manually when an integrating factor can be found just by integration. At the end, we show you how to solve it directly.

Let’s solve the differential equation \( y' = y / (x + y \log y) \).

\begin{verbatim}
Using the notation \( m(x, y) + n(x, y) y' = 0 \), we have \( m = -y \) and \( n = x + y \log y \).
\begin{spad}
m := -y \end{spad}
\begin{spad}
n := x + y * log y \end{spad}

We first check for exactness, that is, does \( \frac{dm}{dy} = \frac{dn}{dx} \)?
\begin{spad}
D(m, y) - D(n, x) \end{spad}

This is not zero, so the equation is not exact. Therefore we must look for an integrating factor: a function \( \mu(x, y) \) such that \( \frac{d(\mu m)}{dy} = \frac{d(\mu n)}{dx} \).

Normally, we first search for \( \mu(x, y) \) depending only on \( \mu(x) \) or only on \( \mu(y) \).
\begin{verbatim}
Let’s search for such a \( \mu(x) \) first.
\begin{spad}
mu := operator 'mu \end{spad}
\end{verbatim}

\begin{verbatim}
\begin{spad}
a := D(mu(x) * m, y) - D(mu(x) * n, x) \end{spad}
\end{verbatim}
If the above is zero for a function \(\text{mu} \) that does not depend on \(\text{y} \), then \(\text{mu(x)} \) is an integrating factor.

\[
\text{solve}(a = 0, \text{mu}, x) \quad \text{free{mu a}}
\]

The solution depends on \(\text{y} \), so there is no integrating factor that depends on \(\text{x} \) only.

Let’s look for one that depends on \(\text{y} \) only.

\[
\text{solve}(b := \text{D(mu(y) * m, y)} - \text{D(mu(y) * n, x) \ text{bound{b)\ free{mu m}}}
\]

\[
\text{solve(b = 0, mu, y) \ free{mu b}\ bound{sb}}
\]

We’ve found one!

The above \(\text{mu(y)} \) is an integrating factor. We must multiply our initial equation (that is, \(\text{m} \) and \(\text{n} \)) by the integrating factor.

\[
\text{intFactor := sb.basis.1 \ text{bound{intFactor}\ free{sb}}}
\]

\[
\text{m := intFactor * m \ text{bound{m1}\ free{m intFactor}}}
\]

\[
\text{n := intFactor * n \ text{bound{n1}\ free{n intFactor}}}
\]

Let’s check for exactness.

\[
\text{D(m, y) - D(n, x) \ free{m1 n1}}
\]

We must solve the exact equation, that is, find a function \(\text{s(x,y)} \) such that \(\text{ds/dx = m} \) and \(\text{ds/dy = n} \).
We start by writing \( s(x, y) = h(y) + \int m(x) \) where \( h(y) \) is an unknown function of \( y \). This guarantees that \( \frac{ds}{dx} = m \).

\[
\begin{align*}
  \text{We start by writing } & \quad s(x, y) = h(y) + \int m(x) \\
  \text{where } & \quad h(y) \text{ is an unknown function of } y. \\
  \text{This guarantees that } & \quad \frac{ds}{dx} = m. \\
\end{align*}
\]

\[
\begin{align*}
  h & \quad \text{operator } h \\
  \text{sol} & \quad = h(y) + \int m(x) \\
  \text{The above particular solution is the } & \quad h(y) \text{ we want, so we just replace } h(y) \text{ by it in the implicit solution.} \\
\end{align*}
\]

A first integral of the initial equation is obtained by setting this result equal to an arbitrary constant.

Now that we’ve seen how to solve the equation ‘‘by hand,’’ we show you how to do it with the \texttt{solve} operation.

\[
\begin{align*}
  \text{First define } y \text{ to be an operator.} \\
  \text{Next we create the differential equation.} \\
  \text{Finally, we solve it.}
\end{align*}
\]

The command to solve differential equations in power series around a particular initial point with specific initial conditions is called \texttt{seriesSolve}. It can take a variety of parameters, so we illustrate its use with some examples.

\begin{verbatim}
Since the coefficients of some solutions are quite large, we reset the default to compute only seven terms.
\end{verbatim}

You can solve a single nonlinear equation of any order. For example, we solve \texttt{axiom(y'''' = sin(y'') * exp(y) + cos(x))} subject to \texttt{axiom(y(0) = 1, y'(0) = 0, y''(0) = 0)}.

We first tell Axiom
that the symbol \texttt{\texttt{\texttt{axiom}'y}} denotes a new operator.
\spadpaste{y := operator 'y \bound{y}}

Enter the differential equation using \texttt{\texttt{axiom}'y} like any system function.
\spadpaste{eq := D(y(x), x, 3) - \sin(D(y(x), x, 2))*exp(y(x)) = \cos(x)\bound{eq}\free{y}}

Solve it around \texttt{\texttt{axiom}'x = 0} with the initial conditions
\texttt{\texttt{axiom}'y(0) = 1, y'(0) = y''(0) = 0}. 
\spadpaste{seriesSolve(eq, y, x = 0, [1, 0, 0])\free{y}\free{eq}\free{c7}}

You can also solve a system of nonlinear first order equations. For example, we solve a system that has \texttt{\texttt{axiom}'tan(t)} and \texttt{\texttt{axiom}'sec(t)} as solutions.
\spadpaste{x := operator 'x\bound{x}}

Enter the two equations forming our system.
\spadpaste{eq1 := D(x(t), t) = 1 + x(t)**2\free{x}\free{eq1}}
\spadpaste{eq2 := D(y(t), t) = x(t) * y(t)\free{x}\free{eq2}}

Solve the system around \texttt{\texttt{axiom}'t = 0} with the initial conditions \texttt{\texttt{axiom}'x(0) = 0} and \texttt{\texttt{axiom}'y(0) = 1}. Notice that since we give the unknowns in the order \texttt{\texttt{axiom}'[x, y]}, the answer is a list of two series in the order \texttt{\texttt{axiom}'[series for x(t), series for y(t)]}. 
\spadpaste{seriesSolve([[eq2, eq1], [x, y], t = 0, [y(0) = 1, x(0) = 0]]\free{x}\free{eq1}\free{eq2}\free{c7}}
\noindent
The order in which we give the equations and the initial conditions has no effect on the order of the solution.
\begin{spadcommand}
eq := \frac{d^3(y(x), x, 3) - \sin(\frac{d^2(y(x), x, 2)}{\exp(y(x))} = \cos(x)}
\end{spadcommand}

\begin{spadcommand}
\text{seriesSolve(eq, y, x = 0, [1, 0, 0])}
\end{spadcommand}

\begin{verbatim}
(3)
\begin{align*}
1 & + x & + x & + x & + x \\
6 & 24 & 120 & 720 & \\
+ & 4 & 2 & \%e & - 8\%e & + 4\%e & + 1 & 7 & 8 \\
& & & & & & x & + O(x ) & 5040
\end{align*}

Finite Fields

in Section 8.11.1. There are several ways of implementing extensions of finite fields, and Axiom provides quite a bit of freedom to allow you to choose the one that is best for your application. Moreover, we provide operations for converting among the different representations of extensions and different extensions of a single field. Finally, note that you usually need to package-call operations from finite fields if the operations do not take as an argument an object of the field. See "Package Calling and Target Types" in Section 2.9 for more information on package-calling.

→ ug08.ht →

A \{it finite field\} (also called a \{it Galois field\}) is a
finite algebraic structure where one can add, multiply and divide under the same laws (for example, commutativity, associativity or distributivity) as apply to the rational, real or complex numbers. Unlike those three fields, for any finite field there exists a positive prime integer \( p \), called the characteristic, such that

\[ p \cdot x = 0 \]

for any element \( x \) in the finite field. In fact, the number of elements in a finite field is a power of the characteristic and for each prime \( p \) and positive integer \( n \) there exists exactly one finite field with

\[ p^n \]

When \( n = 1 \), the field has \( p \) elements and is called a prime field, discussed in the next section.

There are several ways of implementing extensions of finite fields, and Axiom provides quite a bit of freedom to allow you to choose the one that is best for your application. Moreover, we provide operations for converting among the different representations of extensions and different extensions of a single field.

Finally, note that you usually need to package-call operations from finite fields if the operations do not take as an argument an object of the field.

See \( \text{``Package Calling and Target Types''} \) in Section 2.9 for more information on package-calling.
Modular Arithmetic and Prime Fields

Let \( n \) be a positive integer. It is well known that you can get the same result if you perform addition, subtraction or multiplication of integers and then take the remainder on dividing by \( n \) as if you had first done such remaindering on the operands, performed the arithmetic and then (if necessary) done remaindering again. This allows us to speak of arithmetic \( \text{mod} \ n \) or, more simply \( \text{mod} \ n \).

In Axiom, you use \axiomType{IntegerMod} to do such arithmetic.

```
(a, b) : IntegerMod 12
(a, b) := (16, 7)
[a - b, a * b]
```

If \( n \) is not prime, there is only a limited notion of reciprocals and division.
\spadpaste{a / b \free{a b}}
}
\xtc{
\spadpaste{recip a \free{a}}
}
\xtc{
Here \axiom{7} and \axiom{12} are relatively prime, so \axiom{7} has a multiplicative inverse modulo \axiom{12}.
}
\spadpaste{recip b \free{b}}
)

If we take \smath{n} to be a prime number \smath{p}, then taking inverses and, therefore, division are generally defined.
\xtc{
Use \axiomType{PrimeField} instead of \axiomType{IntegerMod} for \smath{n} prime.
}
\spadpaste{c : PrimeField 11 := 8 \bound{c}}
}
\xtc{
\spadpaste{inv c \free{c}}
}
\xtc{
You can also use \axiom{1/c} and \axiom{c**(1)} for the inverse of \smath{c}.
}
\spadpaste{9/c \free{c}}
)

\axiomType{PrimeField} (abbreviation \axiomType{PF}) checks if its argument is prime when you try to use an operation from it. If you know the argument is prime (particularly if it is large), \axiomType{InnerPrimeField} (abbreviation \axiomType{IPF}) assumes the argument has already been verified to be prime. If you do use a number that is not prime, you will eventually get an error message, most likely a division by zero message. For computer science applications, the most important finite fields are \axiomType{PrimeField 2} and its extensions.

\xtc{
In the following examples, we work with the finite field with \smath{p = 101} elements.

When you want to work with an extension of a finite field in Axiom, you have three choices to make:

---

Extensions of Finite Fields

---

ug08.ht ---

When you want to work with an extension of a finite field in Axiom, you have three choices to make:
Do you want to generate an extension of the prime field (for example, \texttt{PrimeField 2}) or an extension of a given field? Do you want to use a representation that is particularly efficient for multiplication, exponentiation and addition but uses a lot of computer memory (a representation that models the cyclic group structure of the multiplicative group of the field extension and uses a Zech logarithm table), one that uses a normal basis for the vector space structure of the field extension, or one that performs arithmetic modulo an irreducible polynomial? The cyclic group representation is only usable up to ‘‘medium’’ (relative to your machine’s performance) sized fields. If the field is large and the normal basis is relatively simple, the normal basis representation is more efficient for exponentiation than the irreducible polynomial representation. Do you want to provide a polynomial explicitly, a root of which ‘‘generates’’ the extension in one of the three senses in (2), or do you wish to have the polynomial generated for you?

This illustrates one of the most important features of Axiom: you can choose exactly the right data-type and representation to suit your application best.

We first tell you what domain constructors to use for each case above, and then give some examples.

Constructors that automatically generate extensions of the prime field:

\begin{itemize}
\item[a] \texttt{FiniteField}
\item[b] \texttt{FiniteFieldCyclicGroup}
\item[c] \texttt{FiniteFieldNormalBasis}
\end{itemize}

Constructors that generate extensions of an arbitrary field:

\begin{itemize}
\item[a] \texttt{FiniteFieldExtension}
\item[b] \texttt{FiniteFieldExtensionByPolynomial}
\item[c] \texttt{FiniteFieldCyclicGroupExtension}
\item[d] \texttt{FiniteFieldCyclicGroupExtensionByPolynomial}
\item[e] \texttt{FiniteFieldNormalBasisExtension}
\item[f] \texttt{FiniteFieldNormalBasisExtensionByPolynomial}
\end{itemize}
Constructors that use a cyclic group representation:
\texttt{FiniteFieldCyclicGroup} \newline\texttt{FiniteFieldCyclicGroupExtension} \newline\texttt{FiniteFieldCyclicGroupExtensionByPolynomial}

Constructors that use a normal basis representation:
\texttt{FiniteFieldNormalBasis} \newline\texttt{FiniteFieldNormalBasisExtension} \newline\texttt{FiniteFieldNormalBasisExtensionByPolynomial}

Constructors that use an irreducible modulus polynomial representation:
\texttt{FiniteField} \newline\texttt{FiniteFieldExtension} \newline\texttt{FiniteFieldCyclicGroup} \newline\texttt{FiniteFieldCyclicGroupExtension} \newline\texttt{FiniteFieldNormalBasis} \newline\texttt{FiniteFieldNormalBasisExtension}

Constructors for which you provide a polynomial:
\texttt{FiniteFieldExtensionByPolynomial} \newline\texttt{FiniteFieldCyclicGroupExtensionByPolynomial} \newline\texttt{FiniteFieldNormalBasisExtensionByPolynomial}

These constructors are discussed in the following sections where we collect together descriptions of extension fields that have the same underlying representation.\footnote{For more information on the implementation aspects of finite fields, see J. Grabmeier, A. Scheerhorn, \textit{Finite Fields in AXIOM.} Technical Report, IBM Heidelberg Scientific Center, 1992.}

If you don't really care about all this detail, just use \texttt{FiniteField}. As your knowledge of your application and its Axiom implementation grows, you can come back and choose an alternative constructor that
may improve the efficiency of your code. Note that the exported operations are almost the same for all constructors of finite field extensions and include the operations exported by \axiomType{PrimeField}.

Irreducible Mod Polynomial Representations

⇒ “notitle” (ugxProblemFiniteExtensionFinitePage) 12 on page 2246 — ugo8.ht —

\begin{page}{ugxProblemFiniteModulusPage}

{8.11.3. Irreducible Mod Polynomial Representations}

\beginscroll
All finite field extension constructors discussed in this section use a representation that performs arithmetic with univariate (one-variable) polynomials modulo an irreducible polynomial. This polynomial may be given explicitly by you or automatically generated. The ground field may be the prime field or one you specify. See \downlink{‘‘Extensions of Finite Fields’’} {ugxProblemFiniteExtensionFinitePage} in Section 8.11.2 \ignore{ugxProblemFiniteExtensionFinite} for general information about finite field extensions.

For \axiomType{FiniteField} (abbreviation \axiomType{FF}) you provide a prime number \math{p} and an extension degree \math{n}. This degree can be 1.

%\xtc{Axiom uses the prime field \axiomType{PrimeField(p)}, here \axiomType{PrimeField 2}, and it chooses an irreducible polynomial of degree \math{n}, here 12, over the ground field.}
{\spadpaste{GF4096 := FF(2,12); \bound{GF4096}}}
The objects in the generated field extension are polynomials of degree at most \(n-1\) with coefficients in the prime field. The polynomial indeterminate is automatically chosen by Axiom and is typically something like \(\text{axiom}(\%A)\) or \(\text{axiom}(\%D)\). These (strange) variables are \{it only\} for output display; there are several ways to construct elements of this field.

The operation \(\text{axiomFun(index)}\) enumerates the elements of the field extension and accepts as argument the integers from 1 to \(\mathbb{p}^{\star n}\).

\%\xc{\text{The expression}} \(\text{axiom(index}(p)\}\) always gives the indeterminate.\}\{\spad{a := index(2)\$GF4096 \text{bound}(a)\text{free(GF4096)})}\}\%\%\xc{\text{You can build polynomials in }a\text{ and calculate in }\text{axiom(GF4096)}.}\}\{\spad{b := a**12 - a**5 + a \text{bound(b)free(a)})}\}\xc{\text{}}\}\{\spad{b ** 1000 \text{free(b)}}\}\xc{\text{}}\}\{\spad{c := a/b \text{free(a b)bound(c)}}\}\%\xc{\text{Among the available operations are }\text{axiomFun(norm)}\text{ and }\text{axiomFun(trace)}.}\}\{\spad{\text{norm c free(c)}}\}\xc{\text{}}\}\{\spad{\text{trace c free(c)}}\}\%\%\xc{\text{}}

Since any nonzero element is a power of a primitive element, how do we discover what the exponent is?\%
The operation \texttt{discreteLog} calculates the exponent and, if it is called with only one argument, always refers to the primitive element returned by \texttt{primitiveElement}.

\begin{verbatim}
\spad{dL := discreteLog a \free{a}\bound{dL}}
\end{verbatim}

\begin{verbatim}
\spad{g ** dL \free{dL g}}
\end{verbatim}

\texttt{FiniteFieldExtension} (abbreviation \texttt{FFX}) is similar to \texttt{FiniteField} except that the ground-field for \texttt{FiniteFieldExtension} is arbitrary and chosen by you.

\begin{verbatim}
\spad{GF16 := FF(2,4); \bound{GF16}}
\end{verbatim}

\begin{verbatim}
\spad{GF4096 := FFX(GF16,3); \bound{GF4096x}\free{GF16}}
\end{verbatim}

\begin{verbatim}
\spad{r := (random()\$GF4096) ** 20 \free{GF4096x}\bound{r}}
\end{verbatim}

\begin{verbatim}
\spad{norm(r) \free{r}}
\end{verbatim}

\texttt{FiniteFieldExtensionByPolynomial} (abbreviation \texttt{FFP}) is similar to \texttt{FiniteField} and \texttt{FiniteFieldExtension} but is more general.

\begin{verbatim}
\spad{GF4 := FF(2,2); \bound{GF4}}
\end{verbatim}

\begin{verbatim}
\spad{f := nextIrreduciblePoly(random(6)\$FFPOLY(GF4))\$FFPOLY(GF4)}
\end{verbatim}
For \axiomType{FFP} you choose both the ground field and the irreducible polynomial used in the representation. The degree of the extension is the degree of the polynomial.

In every finite field there exist elements whose powers are all the nonzero elements of the field. Such an element is called a primitive element.

In \axiomType{FiniteFieldCyclicGroup} (abbreviation \axiomType{FFCG}) the nonzero elements are represented by the powers of a fixed primitive element of the field (that is, a generator of its cyclic multiplicative group). Multiplication (and hence exponentiation) using this representation is easy. To do addition, we consider our primitive element as the root of a primitive polynomial (an irreducible polynomial whose roots are all primitive). See \downlink{``Utility Operations for Finite Fields''} in Section 8.11.7 for examples of how to compute such a polynomial.

\xtc{
To use \axiomType{FiniteFieldCyclicGroup} you provide a prime number and an extension degree.
\}
\spadpaste{GF81 := FFCG(3,4); \bound{GF81}}
\%
\%
\xtc{
Axiom uses the prime field, here \axiomType{PrimeField 3}, as the ground field and it chooses a primitive polynomial of degree \smath{n}, here 4, over the prime field.
\}
\spadpaste{a := primitiveElement()$GF81 \bound{a}\free{GF81}}
\%
\%
\xtc{
You can calculate in \axiom{GF81}.
\}
\spadpaste{b := a**12 - a**5 + a \bound{b}\free{a}}

In this representation of finite fields the discrete logarithm of an element can be seen directly in its output form.
```
\spadpaste{b \free{b}}
```
```
\spadpaste{discreteLog b \free{b}}
```

\axiomType{FiniteFieldCyclicGroupExtension} (abbreviation \axiomType{FFCGX}) is similar to \axiomType{FiniteFieldCyclicGroup} except that the ground field for \axiomType{FiniteFieldCyclicGroupExtension} is arbitrary and chosen by you. In case you select the prime field as ground field, there is essentially no difference between the constructed two finite field extensions.
```
\spadpaste{GF9 := FF(3,2); \bound{GF9}}
```
```
\spadpaste{GF729 := FFCGX(GF9,3); \bound{GF729}\free{GF9}}
```
```
\spadpaste{r := (random()\$GF729) ** 20 \free{GF729}\bound{r}}
```
```
\spadpaste{trace(r) \free{r}}
```

\axiomType{FiniteFieldCyclicGroupExtensionByPolynomial} (abbreviation \axiomType{FFCGP}) is similar to \axiomType{FiniteFieldCyclicGroup} and \axiomType{FiniteFieldCyclicGroupExtension} but is more general. For \axiomType{FiniteFieldCyclicGroupExtensionByPolynomial} you choose both the ground field and the irreducible polynomial used in the representation. The degree of the extension is the degree of the polynomial.
```
\spadpaste{GF3 := PrimeField 3; \bound{GF3}}
```
We use a utility operation to generate an irreducible primitive polynomial (see Section 8.11.7 in "Utility Operations for Finite Fields"). The polynomial has one variable that is "anonymous": it displays as a question mark.

\begin{verbatim}
f := createPrimitivePoly(4)\$FFPOLY(GF3) \bound{f}\free{GF3}
\end{verbatim}

\begin{verbatim}
GF81 := FFCGP(GF3,f); \bound{GF81x}\free{f GF3}
\end{verbatim}

Let's look at a random element from this field.

Normal Basis Representations

⇒ “notitle” (ugxProblemFiniteUtilityPage) 12 on page 2280 — ug08.ht —

{8.11.5. Normal Basis Representations}

beginscroll
Let $K$ be a finite extension of degree $n$ of the finite field $F$ and let $F$ have $q$ elements.

An element $x$ of $K$ is said to be normal over $F$ if the elements $1, x^q, x^{q^2}, \ldots, x^{q^{(n-1)}}$ form a basis of $K$ as a vector space over $F$.

Such a basis is called a normal basis. This agrees with the general definition of a normal basis because the $n$ distinct powers of the automorphism $x \mapsto x^q$ constitute the Galois group of $K/F$.

If $x$ is normal over $F$, its minimal polynomial is also said to be normal over $F$.

There exist normal bases for all finite extensions of arbitrary finite fields.

In $\text{FiniteFieldNormalBasis}$ (abbreviation $\text{FFNB}$), the elements of the finite field are represented by coordinate vectors with respect to a normal basis.

\xtc{You provide a prime $p$ and an extension degree $n$.}{
\spadpaste{K := FFNB(3,8) \bound{K}}\free{K}
}

Axiom uses the prime field $\text{PrimeField}(p)$, here $\text{PrimeField}(3)$, and it chooses a normal polynomial of degree $n$, here 8, over the ground field. The remainder class of the indeterminate is used as the normal element. The polynomial indeterminate is automatically chosen by Axiom and is typically something like $\text{\%A}$ or $\text{\%D}$. These (strange) variables are only for output display; there are several ways to construct elements of this field. The output of the basis elements is something like $\text{%A}^{q^i}$.

\xtc{a := normalElement()\$K \bound{a}\free{K}}
You can calculate in $\mathbb{K}$ using $\mathbb{a}$.

$\texttt{b := a**12 - a**5 + a \bound{b}\free{a}}$

\textit{axiomType}{FiniteFieldNormalBasisExtension} (abbreviation \textit{axiomType}{FFNBX}) is similar to \textit{axiomType}{FiniteFieldNormalBasis} except that the groundfield for \textit{axiomType}{FiniteFieldNormalBasisExtension} is arbitrary and chosen by you. In case you select the prime field as ground field, there is essentially no difference between the constructed two finite field extensions.

$\texttt{GF9 := FFNB(3,2); \bound{GF9}}$

$\texttt{GF729 := FFNBX(GF9,3); \bound{GF729}\free{GF9}}$

$\texttt{r := random()$GF729 \bound{r}\free{GF729}}$

$\texttt{r + r**3 + r**9 + r**27 \free{r}}$

\textit{axiomType}{FiniteFieldNormalBasisExtensionByPolynomial} (abbreviation \textit{axiomType}{FFNBP}) is similar to \textit{axiomType}{FiniteFieldNormalBasis} and \textit{axiomType}{FiniteFieldNormalBasisExtension} but is more general. For \textit{axiomType}{FiniteFieldNormalBasisExtensionByPolynomial} you choose both the ground field and the irreducible polynomial used in the representation.

The degree of the extension is the degree of the polynomial.

We use a utility operation to generate an irreducible normal
polynomial (see `Utility Operations for Finite Fields`).

The polynomial has one variable that is "anonymous": it displays as a question mark.

Conversion Operations for Finite Fields

Let $K$ be a finite field.

An extension field $K_m$ of degree $m$ over $K$ is a subfield of an extension field $K_n$ of degree $n$ over $K$ if and only if $m$ divides $n$.

\begin{verbatim}
Kn | Km \Longleftrightarrow m \mid n | K
\end{verbatim}

\texttt{FiniteFieldHomomorphisms} provides conversion operations between different extensions of one fixed finite ground field and between different representations of these finite fields.

Let's choose $m$ and $n$,

\texttt{(m,n) := (4,8) \bound{m n}}
build the field extensions,
\}
\spadpaste{Km := FiniteFieldExtension(K,m) \bound{Km}\free{K m}}
\}
\xtc{
and pick two random elements from the smaller field.
}\}
\spadpaste{Kn := FiniteFieldExtension(K,n) \bound{Kn}\free{K n}}
\}
\xtc{
}\}
\spadpaste{a1 := random()\$Km \bound{a1}\free{Km}}
\}
\xtc{
}\}

Utility Operations for Finite Fields

--- ug08.ht ---

\axiomType{FiniteFieldPolynomialPackage} (abbreviation \axiomType{FFPOLY}) provides operations for generating, counting and testing polynomials over finite fields. Let's start with a couple of definitions:

\begin{itemize}
\item A polynomial is \textit{primitive} if its roots are primitive elements in an extension of the coefficient field of degree equal to the degree of the polynomial.
\item A polynomial is \textit{normal} over its coefficient field if its roots are linearly independent elements in an extension of the coefficient field of degree equal to the degree of the polynomial.
\end{itemize}
In what follows, many of the generated polynomials have one ‘anonymous’ variable. This indeterminate is displayed as a question mark (\texttt{?}).

To fix ideas, let’s use the field with five elements for the first few examples.

\begin{verbatim}
GF5 := PF 5; \texttt{GF5}
\end{verbatim}

You can generate irreducible polynomials of any (positive) degree (within the storage capabilities of the computer and your ability to wait) by using

\begin{verbatim}
createIrreduciblePoly\{FiniteFieldPolynomialPackage\}.
\end{verbatim}

\begin{verbatim}
f := createIrreduciblePoly(8)\$FFPOLY(GF5) \texttt{f}
\end{verbatim}

Does this polynomial have other important properties? Use \texttt{primitive?} to test whether it is a primitive polynomial.

\begin{verbatim}
primitive?(f)\$FFPOLY(GF5) \texttt{f}
\end{verbatim}

Use \texttt{normal?} to test whether it is a normal polynomial.

\begin{verbatim}\nnormal?(f)\$FFPOLY(GF5) \texttt{f}
\end{verbatim}

Note that this is actually a trivial case, because a normal polynomial of degree \(n\) must have a nonzero term of degree \(n-1\). We will refer back to this later.

To get a primitive polynomial of degree 8 just issue this.

\begin{verbatim}
p := createPrimitivePoly(8)\$FFPOLY(GF5) \texttt{p}
\end{verbatim}

This polynomial is not normal,
but if you want a normal one simply write this.

This polynomial is not primitive!

This could have been seen directly, as the constant term is 1 here, which is not a primitive element up to the factor \((\texttt{-1})\) raised to the degree of the polynomial.\footnote{Cf. Lidl, R. \& Niederreiter, H., \textit{Finite Fields}, Encycl. of Math. 20, (Addison-Wesley, 1983), p.90, Th. 3.18.}

What about polynomials that are both primitive and normal? The existence of such a polynomial is by no means obvious.\footnote{The existence of such polynomials is proved in Lenstra, H. W. \& Schoof, R. J., \textit{Primitive Normal Bases for Finite Fields}, Math. Comp. 48, 1987, pp. 217-231.}

If you really need one use either \texttt{createPrimitiveNormalPoly(8)\$FFPOLY(GF5) \free{GF5}} or \texttt{createNormalPrimitivePoly(8)\$FFPOLY(GF5) \free{GF5}}.

If you want to obtain additional polynomials of the various types above as given by the \texttt{create...} operations above, you can use the \texttt{next...} operations. For instance, \texttt{nextIrreduciblePoly(8)\$FFPOLY(GF5) \free{GF5}} yields the next monic irreducible polynomial with the same degree as the input polynomial. By ‘‘next’’ we mean ‘‘next in a natural order using the terms and coefficients.’’ This will become more clear in the following examples.

This is the field with five elements.
Our first example irreducible polynomial, say of degree 3, must be "greater" than this.

You can generate it by doing this.

You can step through all irreducible polynomials of degree 8 over the field with 5 elements by repeatedly issuing this.

You could also ask for the total number of these.

We hope that "natural order" on polynomials is now clear: first we compare the number of monomials of two polynomials ("more" is "greater"); then, if necessary, the degrees of these monomials (lexicographically), and lastly their coefficients (also lexicographically, and using the operation \texttt{axiomFun\{lookup\}} if our field is not a prime field).

Also note that we make both polynomials monic before looking at the coefficients: multiplying either polynomial by a nonzero constant produces the same result.

The package \texttt{axiomType\{FiniteFieldPolynomialPackage\}} also provides similar operations for primitive and normal polynomials. With
the exception of the number of primitive normal polynomials; we're not aware of any known formula for this.

\spad{numberOfPrimitivePoly(3) \text{\texttt{FFPOLY(GF5)}}}
\%
\%
xtc{Take these,
}\{
\spad{m := monomial(1,1) \text{\texttt{SUP(GF5)}} \text{\texttt{bound(m)}}\text{\texttt{free(GF5)}}}
\}
\xtc{
}\{
\spad{f := m**3 + 4*m**2 + m + 2 \text{\texttt{bound(fx)}}\text{\texttt{free(m)}}}
\}%
\%
\%
\xtc{and then we have:
}\{
\spad{f1 := nextPrimitivePoly(f) \text{\texttt{FFPOLY(GF5)}} \text{\texttt{free(fx)}}\text{\texttt{bound(f1)}}}
\}
\xtc{What happened?
}\{
\spad{nextPrimitivePoly(f1) \text{\texttt{FFPOLY(GF5)}} \text{\texttt{free(f1)}}}
}\%
\%
Well, for the ordering used in
\axiomFunFrom{nextPrimitivePoly}{FiniteFieldPolynomialPackage} we use as first criterion a comparison of the constant terms of the polynomials. Analogously, in
\axiomFunFrom{nextNormalPoly}{FiniteFieldPolynomialPackage} we first compare the monomials of degree 1 less than the degree of the polynomials (which is nonzero, by an earlier remark).
\%
\xtc{
}\{
\spad{f := m**3 + m**2 + 4*m + 1 \text{\texttt{bound(fy)}}\text{\texttt{free(m)}}}
\}
\xtc{
}\{
\spad{f1 := nextNormalPoly(f) \text{\texttt{FFPOLY(GF5)}} \text{\texttt{free(fy)}}\text{\texttt{bound(f1y)}}}
\}
\xtc{
}\{
\spad{nextNormalPoly(f1) \text{\texttt{FFPOLY(GF5)}} \text{\texttt{free(f1y)}}}
\}
We don't have to restrict ourselves to prime fields.

Let's consider, say, a field with 16 elements.
\begin{verbatim}
GF16 := FFX(FFX(PF 2,2),2); \free{GF16}
\end{verbatim}

We can apply any of the operations described above.
\begin{verbatim}
createIrreduciblePoly(5)\$FFPOLY(GF16) \free{GF16}
\end{verbatim}

Axiom also provides operations
for producing random polynomials of a given degree
\begin{verbatim}
random(5)\$FFPOLY(GF16) \free{GF16}
\end{verbatim}

or with degree between two given bounds.
\begin{verbatim}
random(3,9)\$FFPOLY(GF16) \free{GF16}
\end{verbatim}

\axiomType{FiniteFieldPolynomialPackage2} (abbreviation \axiomType{FFPOLY2}) exports an operation \axiomFun{rootOfIrreduciblePoly} for finding one root of an irreducible polynomial \axiom{f} in an extension field of the coefficient field.

The degree of the extension has to be a multiple of the degree of \axiom{f}.

It is not checked whether \axiom{f} actually is irreducible.

To illustrate this operation, we fix a ground field \axiom{GF}
\begin{verbatim}
GF2 := PrimeField 2; \free{GF2}
\end{verbatim}

and then an extension field.
\begin{verbatim}
F := FFX(GF2,12) \free{F}\free{GF2}
\end{verbatim}
We construct an irreducible polynomial over \axiom{GF2}.

\spadpaste{\texttt{f := createIrreduciblePoly(6)$\texttt{FFPOLY(GF2)}}}

\indentrel{-3}\begin{verbatim}
8 4
(2) ? + ? + 2
Type: \texttt{SparseUnivariatePolynomial PrimeField 5}
\end{verbatim}

We compute a root of \axiom{f}.

\spadpaste{\texttt{root := rootOfIrreduciblePoly(f)$\texttt{FFPOLY2(F,GF2)}}}

and check the result

\spadcommand{\texttt{eval(f, monomial(1,1)$\texttt{SUP(F)} = root) $\texttt{free(fz F root)}}}

As a sample use of Axiom’s algebraic number facilities, we compute the Galois group of the polynomial $p(x) = x^5 - 5x + 12$.

We would like to construct a polynomial $f(x)$ such that the splitting field of $p(x)$ is generated by one root of $f(x)$. First we construct a polynomial $r = r(x)$ such that one root of $r(x)$ generates the field generated by two roots of the polynomial $p(x)$. (As it will turn out, the field generated by two roots of $p(x)$ is, in fact, the splitting field of $p(x)$.)

From the proof of the primitive element theorem we know that if $a$ and $b$ are algebraic numbers, then the field $\mathbb{Q}(a+b)$ is equal to $\mathbb{Q}(a+kb)$ for an appropriately chosen integer $k$. In our case, we construct the minimal polynomial of $a[i] - a[j]$, where $a[i]$ and $a[j]$ are two roots of $p(x)$. We construct this polynomial using `resultant`. The main result we need is the following: If $f(x)$ is a polynomial with roots $a[1]...a[m]$ and $g(x)$ is a polynomial with roots $b[1]...b[n]$, then the polynomial $h(x) = \text{resultant}(f(y), g(x-y), y)$ is a polynomial of degree $m*n$ with roots $a[i] + b[j]$, $1 <= i <= m, 1 <= j <= n$.

For $f(x)$ we use the polynomial $p(x)$. For $g(x)$ we use the...
root of \(r(x)\) generates the field generated by two roots of the polynomial \(p(x)\).

(As it will turn out, the field generated by two roots of \(p(x)\) is, in fact, the splitting field of \(p(x)\).)

From the proof of the primitive element theorem we know that if \(a\) and \(b\) are algebraic numbers, then the field \(\mathbb{Q}(a, b)\) is equal to \(\mathbb{Q}(a + k b)\) for an appropriately chosen integer \(k\).

In our case, we construct the minimal polynomial of \(a_i - a_j\), where \(a_i\) and \(a_j\) are two roots of \(p(x)\). We construct this polynomial using \(\text{resultant}\).

The main result we need is the following: If \(f(x)\) is a polynomial with roots \(a_1 \ldots a_m\) and \(g(x)\) is a polynomial with roots \(b_1 \ldots b_n\), then the polynomial \(h(x) = \text{resultant}(f(y), g(x-y), y)\) is a polynomial of degree \(m*n\) with roots \(a_i + b_j, i = 1 \ldots m, j = 1 \ldots n\).

For \(f(x)\) we use the polynomial \(p(x)\). For \(g(x)\) we use the polynomial \(-p(-x)\). Thus, the polynomial we first construct is \(\text{resultant}(p(y), -p(-x), y)\).

\(\spad{q := \text{resultant}(\text{eval}(p,x,y),-\text{eval}(p,x,y-x),y) \free{p} \bound{q}}\)

The roots of \(q(x)\) are \(a_i - a_j, i \leq 1, j \leq 5\) \(\axiom{a[i] - a[j], 1 <= i,j <= 5}\).

Of course, there are five pairs \(a_i = a_j\), so \(\text{resultant}(0)\) is a 5-fold root of \(q(x)\).

\(\spad{q1 := \text{exquo}(q, x**5) \free{q} \bound{q1}}\)
Factor the polynomial \( q_1 \).
\[
\text{\texttt{\spad{factoredQ := factor q1 \free{q1} \bound{factoredQ}}}}
\]

We see that \( q_1 \) has two irreducible factors, each of degree \( 10 \). (The fact that the polynomial \( q_1 \) has two factors of degree \( 10 \) is enough to show that the Galois group of \( p(x) \) is the dihedral group of order \( 10 \).\footnote{See McKay, Soicher, Computing Galois Groups over the Rationals, Journal of Number Theory 20, 273-281 (1983). We do not assume the results of this paper, however, and we continue with the computation.} Note that the type of \( \texttt{factoredQ} \) is \( \texttt{Factored Polynomial Integer} \), that is, \( \texttt{Factored Polynomial Integer} \). This is a special data type for recording factorizations of polynomials with integer coefficients (see \texttt{Factored}).

\xtc{
We can access the individual factors using the operation \( \texttt{nthFactor} \).
\[
\text{\texttt{\spad{r := nthFactor(factoredQ,1) \free{factoredQ} \bound{r}}}}
\]
}

Consider the polynomial \( r(x) \). This is the minimal polynomial of the difference of two roots of \( p(x) \). Thus, the splitting field of \( p(x) \) contains a subfield of degree \( 10 \).

We show that this subfield is, in fact, the splitting field of \( p(x) \) by showing that \( p(x) \) factors completely over this field.
\xtc{
First we create a symbolic root of the polynomial \( r(x) \).
\( \text{We replaced} \ \texttt{x} \ \text{by} \ \texttt{b} \ \text{in the polynomial} \ \texttt{r} \ \text{so that our symbolic root would be printed as} \ \texttt{b}. \)
\[
\text{\texttt{\spad{beta:AN := rootOf(eval(r,x,b)) \free{r} \bound{beta}}}}
\]
\xtc{
We next tell Axiom to view \( p(x) \) as a univariate polynomial in \( x \) with algebraic number coefficients.
This is accomplished with this type declaration.
\[
\text{\texttt{\spad{p := p::UP(x,INT)::UP(x,AN) \free{p} \bound{p}}}}
\]
\texth{$\mathbb{Q}$\{\bf $\beta$\}\{\axiom{Q(beta)}}.
\text{(This computation will take some time!)
\}
\spadpaste{algFactors := factor(p,\[\beta\]) \free{declareP beta}
\bound{algFactors}}
\}
\%
When factoring over number fields, it is important to specify the
field over which the polynomial is to be factored, as polynomials
have different factorizations over different fields.
When you use the operation \axiomFun{factor}, the field over which
the polynomial is factored is the field generated by
\indent(4)
\begin{itemize}
\item[1.] the algebraic numbers that appear
in the coefficients of the polynomial, and
\item[2.] the algebraic numbers that
appear in a list passed as an optional second argument of the operation.
\end{itemize}
\indent(0)
In our case, the coefficients of \axiom{p}
are all rational integers and only \axiom{beta}
appears in the list, so the field is simply
\texth{$\mathbb{Q}$\{\bf $\beta$\}\{\axiom{Q(beta)}}.
\%
It was necessary to give the list \axiom{[beta]} as a second argument of the operation
because otherwise the polynomial would have been factored over the field
generated by its coefficients, namely the rational numbers.
\}
\spadpaste{factor(p) \free{declareP}}
\}%
We have shown that the splitting field of \smath{p(x)} has degree
\axiom{10}.
Since the symmetric group of degree 5 has only one transitive subgroup
of order \axiom{10}, we know that the Galois group of \smath{p(x)} must be
this group, the dihedral group
of order \axiom{10}.
Rather than stop here, we explicitly compute the action of the Galois
group on the roots of \smath{p(x)}.

First we assign the roots of \smath{p(x)} as the values of five
variables.
We can obtain an individual root by negating the constant coefficient of one of the factors of \( p(x) \).

\begin{verbatim}
\spad{factor1 := nthFactor(algFactors,1) \free{algFactors} \bound{factor1}}
\end{verbatim}

\begin{verbatim}
\spad{root1 := -coefficient(factor1,0) \free{factor1} \bound{root1}}
\end{verbatim}

We can obtain a list of all the roots in this way.

\begin{verbatim}
roots := [-coefficient(nthFactor(algFactors,i),0) for i in 1..5] \free{algFactors} \bound{roots}
\end{verbatim}

The expression
\begin{verbatim}
- coefficient(nthFactor(algFactors, i), 0)
\end{verbatim}
is the \( i \)-th root of \( p(x) \) and the elements of \( \text{roots} \) are the \( i \)-th roots of \( p(x) \) as \( i \) ranges from \( 1 \) to \( 5 \).

\begin{verbatim}
(\axiom{a1},\axiom{a2},\axiom{a3},\axiom{a4},\axiom{a5}) := (roots.1,roots.2,roots.3,roots.4,roots.5) \free{roots} \bound{ais}
\end{verbatim}

Next we express the roots of \( r(x) \) as polynomials in \( \beta \). We could obtain these roots by calling the operation \( \text{factor}(r, [\beta]) \) factors \( r(x) \) over \( \mathbb{Q}(\beta) \). However, this is a lengthy computation and we can obtain the roots of \( r(x) \) as differences of the roots \( \text{ais} \) of \( p(x) \). Only ten of these differences are roots of \( r(x) \) and the other ten are roots of the other irreducible factor of \( q1 \). We can determine if a given value is a root of \( r(x) \) by evaluating \( r(x) \) at that particular value. (Of course, the order in which factors are returned by the operation \( \text{factor}(factor) \) is unimportant and may change with different implementations of the operation. Therefore, we cannot predict in advance which differences are roots of \( r(x) \).}
and which are not.

\[
\begin{align*}
&\text{Let's look at four examples (two are roots of } r(x) \text{ and two are not).} \\
&\text{(} \spad{eval(r,x,a1 - a2) \free{ais}}) \\
&\text{(} \spad{eval(r,x,a1 - a3) \free{ais}}) \\
&\text{(} \spad{eval(r,x,a1 - a4) \free{ais}}) \\
&\text{(} \spad{eval(r,x,a1 - a5) \free{ais}}) \\
% \\
&\text{Take one of the differences that was a root of } r(x) \text{ and assign it to the variable } \axiom{bb}. \\
&\text{For example, if } \axiom{eval(r,x,a1 - a4)} \text{ returned } \axiom{0}, \text{ you would enter this.} \\
&\text{(} \spad{bb := a1 - a4 \free{ais} \bound{bb}}) \\
&\text{Of course, if the difference is, in fact, equal to the root } \axiom{beta}, \text{ you should choose another root of } r(x). \\
&\text{Automorphisms of the splitting field are given by mapping a generator of the field, namely } \axiom{beta}, \text{ to other roots of its minimal polynomial. Let's see what happens when } \axiom{beta} \text{ is mapped to } \axiom{bb}. \\
&\text{We compute the images of the roots } \axiom{a1, ..., a5} \text{ under this automorphism:} \\
&\text{(} \spad{aa1 := subst(a1,beta = bb) \free{beta bb ais} \bound{aa1}}) \\
&\text{(} \spad{aa2 := subst(a2,beta = bb) \free{beta bb ais} \bound{aa2}}) \\
&\text{(} \spad{aa3 := subst(a3,beta = bb) \free{beta bb ais} \bound{aa3}})
\end{align*}
\]
Of course, the values \axiom{aa1,...,aa5} are simply a permutation of the values \axiom{a1,...,a5}.

Let’s find the value of \axiom{aa1} (execute as many of the following five commands as necessary).

\begin{verbatim}
(aa1 = a1) :: Boolean \free{aa1}
(aa1 = a2) :: Boolean \free{aa1}
(aa1 = a3) :: Boolean \free{aa1}
(aa1 = a4) :: Boolean \free{aa1}
(aa1 = a5) :: Boolean \free{aa1}
\end{verbatim}

Proceeding in this fashion, you can find the values of \axiom{aa2,...aa5}. Here you should use the \verb|Clef| line editor. See \downlink{``Clef''}{ugAvailCLEF} in Section 1.1.1 for more information about \verb|Clef|. You have represented the automorphism \axiom{beta -> bb} as a permutation of the roots \axiom{a1,...,a5}. If you wish, you can repeat this computation for all the roots of \smath{r(x)} and represent the Galois group of \smath{p(x)} as a subgroup of the symmetric group on five letters.

Here are two other problems that you may attack in a similar fashion:
\begin{itemize}
\item Show that the Galois group of \axiom{aa2,...aa5}.\footnote{Here you should use the \verb|Clef| line editor. See \downlink{``Clef''}{ugAvailCLEF} for more information about \verb|Clef|. You have represented the automorphism \axiom{beta -> bb} as a permutation of the roots \axiom{a1,...,a5}. If you wish, you can repeat this computation for all the roots of \smath{r(x)} and represent the Galois group of \smath{p(x)} as a subgroup of the symmetric group on five letters.} Show that the Galois group of
\[ p(x) = x^4 + 2x^3 - 2x^2 - 3x + 1 \]

is the dihedral group of order eight.

(The splitting field of this polynomial is the Hilbert class field of the quadratic field \( \mathbb{Q}(\sqrt{145}) \).)

\item Show that the Galois group of \[ p(x) = x^6 + 108 \]
has order 6 and is isomorphic to \( S_3 \), the symmetric group on three letters.

(The splitting field of this polynomial is the splitting field of \( x^3 - 2 \).)

Non-Associative Algebras and Genetic Laws

⇒ “notitle” (OctonionXmpPage) 3.81 on page 1044
Many algebraic structures of mathematics and Axiom have a multiplication operation \axiomOp{*} that satisfies the associativity law
\[ a \cdot (b \cdot c) = (a \cdot b) \cdot c \]
for all \smath{a}, \smath{b} and \smath{c}. The octonions (see \downlink{`Octonion'}{OctonionXmpPage} are a well known exception. There are many other interesting non-associative structures, such as the class of Lie algebras. Lie algebras can be used, for example, to analyse Lie symmetry algebras of partial differential equations. In this section we show a different application of non-associative algebras, the modelling of genetic laws.

The Axiom library contains several constructors for creating non-associative structures, ranging from the categories \spadtype{Monad}, \spadtype{NonAssociativeRng}, and \spadtype{FramedNonAssociativeAlgebra}, to the domains \spadtype{AlgebraGivenByStructuralConstants} and \spadtype{GenericNonAssociativeAlgebra}. Furthermore, the package \spadtype{AlgebraPackage} provides operations for analysing the structure of such algebras. The interested reader can learn more about these aspects of the Axiom library from the paper “Computations in Algebras of Finite Rank,” by Johannes Grabmeier and Robert Wisbauer, Technical Report, IBM Heidelberg Scientific Center, 1992.

Mendel’s genetic laws are often written in a form like
\[ Aa \times Aa = \frac{1}{4} AA + \frac{1}{2} Aa + \frac{1}{4} aa. \]
The implementation of general algebras in Axiom allows us to use this as the definition for multiplication in an algebra. Hence, it is possible to study questions of genetic inheritance using Axiom. To demonstrate this more precisely, we discuss one example from a monograph of A. Woerz-Busekros,
where you can also find a general setting of this theory.\footnote{W"{o}rz-Busekros, A., \it Algebras in Genetics, \protect\ Springer Lectures Notes in Biomathematics 36, Berlin e.a. (1980). In particular, see example 1.3.}

We assume that there is an infinitely large random mating population. Random mating of two gametes $a_i$ and $a_j$ gives zygotes $a_ia_j$, which produce new gametes. In classical Mendelian segregation we have $a_ia_j = \frac{1}{2}a_i + \frac{1}{2}a_j$. In general, we have

\begin{equation}
    a_ia_j = \sum_{k=1}^{n} \gamma_{i,j}^k a_k.
\end{equation}

The segregation rates $\gamma_{i,j}$ are the structural constants of an $n$-dimensional algebra. This is provided in Axiom by the constructor \spadtype{AlgebraGivenByStructuralConstants} (abbreviation \spadtype{ALGSC}).

Consider two coupled autosomal loci with alleles $A, a, B, b$, building four different gametes $a_1 = AB, a_2 = Ab, a_3 = aB, a_4 = ab$.

The zygotes $a_ia_j$ produce gametes $a_i$ and $a_j$ with classical Mendelian segregation. Zygote $a_1a_4$ undergoes transition to $a_2a_3$ and vice versa with probability $0 \le \theta \le \frac{1}{2}$.

Define a list of four-by-four matrices giving the segregation rates.

\begin{verbatim}
segregationRates : List SquareMatrix(4,FRAC INT) :=
[ matrix [ [1, 1/2, 1/2, 9/20], [1/2, 0, 1/20, 0], [1/2, 1/20, 0, 0], [9/20, 0, 0, 0] ],
  matrix [ [0, 1/2, 0, 1/20], [1/2, 1, 9/20, 1/2], [0, 9/20, 0, 0], [1/20, 1/2, 0, 0] ],
  matrix [ [0, 0, 1/2, 1/20], [0, 0, 9/20, 1/2], [1/20, 0, 1/2, 0], [0, 1/20, 0, 1/2] ],
  matrix [ [0, 0, 0, 9/20], [0, 0, 1/20, 1/2], [0, 1/20, 0, 1/2], [0, 1/20, 0, 1/2] ] ];
\end{verbatim}
Choose the appropriate symbols for the basis of gametes,
}{
\spadpaste{gametes := ['AB,'Ab,'aB,'ab] \bound{gametes}}
}
\xtc{Define the algebra.}
}{
\spadpaste{A := ALGSC(FRAC INT, 4, gametes, segregationRates);
\bound{A}\free{gametes, segregationRates}}
}
\xtc{What are the probabilities for zygote $a_1a_4$ to produce the different gametes?}
}{
\spadpaste{a := basis()$A; a.1*a.4}}
\xtc{Elements in this algebra whose coefficients sum to one play a
distinguished role.
They represent a population with the distribution of gametes
reflected by the coefficients with respect to the basis of
gametes.
Random mating of different populations $x$ and $y$
is described by their product $x*y$.}
\xtc{This product is commutative only
if the gametes are not sex-dependent, as in our example.}
}{
\spadpaste{commutative?()$A \free{A}}
}
\xtc{In general, it is not associative.}
}{
\spadpaste{associative?()$A \free{A}}
}
\xtc{Random mating within a population $x$ is described by
$x*x.$
The next generation is $(x*x)*(x*x).$}
\xtc{Use decimal numbers to compare the distributions more easily.}
}{
\spadpaste{x : ALGSC(DECIMAL, 4, gametes, segregationRates) :=
[9/20, 1/2, 1/2, 1] \bound{segregationRates}}
}
To compute directly the gametic distribution in the fifth generation, we use \spadfun{plenaryPower}.

\spadpaste{plenaryPower(x,5) \free{x}}

We now ask two questions:
Does this distribution converge to an equilibrium state?
What are the distributions that are stable?

This is an invariant of the algebra and it is used to answer the first question. The new indeterminates describe a symbolic distribution.

\spadpaste{q := leftRankPolynomial()
$\text{GCAALG}(\text{FRAC INT}, 4, \text{gametes, segregationRates}) ::\text{UP}(\text{Y, POLY FRAC INT})\free{q}\text{gametes, segregationRates}}

Because the coefficient $\frac{9}{20}$ has absolute value less than 1, all distributions do converge, by a theorem of this theory.

\spadpaste{factor(q :: POLY FRAC INT) \free{q}}

The second question is answered by searching for idempotents in the algebra.

\spadpaste{cI := conditionsForIdempotents()
$\text{GCAALG}(\text{FRAC INT}, 4, \text{gametes, segregationRates}) \free{cI}\text{gametes, segregationRates}}

Solve these equations and look at the first solution.

\spadpaste{gbs := groebnerFactorize cI; gbs.1\free{cI}\bound{gbs}}

Further analysis using the package \spadtype{PolynomialIdeals} shows that there is a two-dimensional variety of equilibrium states and all other solutions are contained in it.

Choose one equilibrium state by setting two indeterminates to concrete values.
\spadpaste{sol := solve concat(gbs.1, [\%x1-1/10, \%x2-1/10])
 bound{sol} \free{gbs}}}

\xtc{\;
}\spadpaste{e : A := represents reverse (map(rhs, sol.1)
:: List FRAC INT)\bound{e} \free{A, sol}}

\xtc{Verify the result.
}\spadpaste{e*e-e \free{e}}

\begin{page}{ugIntProgPage}{10. Interactive Programming}
\beginscroll

Programming in the interpreter is easy.
So is the use of Axiom’s graphics facility.
Both are rather flexible and allow you to use them for many interesting applications.
However, both require learning some basic ideas and skills.

All graphics examples in the \Gallery{} section are either produced directly by interactive commands or by interpreter programs.
Four of these programs are introduced here.

\endscroll
\end{page}

2337
By the end of this chapter you will know enough about graphics and programming in the interpreter to not only understand all these examples, but to tackle interesting and difficult problems on your own. Appendix G (Appendix G: Graphics) lists all the remaining commands and programs used to create these images.

\begin{menu}

---

**Drawing Ribbons Interactively**

⇒ “notitle” (ugGraphPage) 11 on page 1967

---

We begin our discussion of interactive graphics with the creation of a useful facility: plotting ribbons of two-graphs in three-space.
Suppose you want to draw the \textit{two} \texttt{dim} graphs of \texttt{smath} \( n \) functions \( f_i(x), 1 \leq i \leq n \), all over some fixed range of \texttt{smath} \( x \).

One approach is to create a \texttt{two} \texttt{dim} graph for each one, then superpose one on top of the other.

What you will more than likely get is a jumbled mess.

Even if you make each function a different color, the result is likely to be confusing.

A better approach is to display each of the \texttt{smath} \( f_i(x) \) in three dimensions as a ‘ribbon’ of some appropriate width along the \texttt{smath} \( y \)-direction, laying down each ribbon next to the previous one.

A ribbon is simply a function of \texttt{smath} \( x \) and \texttt{smath} \( y \) depending only on \texttt{smath} \( x \).

We illustrate this for \texttt{smath} \( f_i(x) \) defined as simple powers of \texttt{smath} \( x \) for \texttt{smath} \( x \) ranging between \texttt{smath} \( -1 \) and \texttt{smath} \( 1 \).

\begin{verbatim}
\psXtc{
Draw the ribbon for \texttt{$z = x^2$}{\spad{$z=x ** 2$}}.}
{\graphpaste{draw(x**2,x=-1..1,y=0..1)}}
{\epsffile[0 0 295 295]{../ps/ribbon1.ps}}
\end{verbatim}

Now that was easy!

What you get is a ‘wire-mesh’ rendition of the ribbon.

That’s fine for now.

Notice that the mesh-size is small in both the \texttt{smath} \( x \) and the \texttt{smath} \( y \) directions.

Axiom normally computes points in both these directions.

This is unnecessary.

One step is all we need in the \texttt{smath} \( y \)-direction.

To have Axiom economize on \texttt{spad(y)-points}, we re-draw the ribbon with option \texttt{spad(var2Steps == 1)}.

\begin{verbatim}
\psXtc{
Re-draw the ribbon, but with option \texttt{spad(var2Steps == 1)}
so that only \texttt{spad()} step is computed in the \texttt{smath} \( y \)-direction.}
{\graphpaste{vp := draw(x**2,x=-1..1,y=0..1,var2Steps==1) \bound{d1}}}
{\epsffile[0 0 295 295]{../ps/ribbon2.ps}}
\end{verbatim}

The operation has created a viewport, that is, a graphics window on your screen.
We assigned the viewport to \texttt{vp} and now we manipulate its contents.

Graphs are objects, like numbers and algebraic expressions. You may want to do some experimenting with graphs. For example, say
\begin{verbatim}
showRegion(vp, "on")
\end{verbatim}
to put a bounding box around the ribbon. Try it! Issue \texttt{rotate(vp, -45, 90)} to rotate the figure \texttt{math(-45)} longitudinal degrees and \texttt{math(90)} latitudinal degrees.

\psXtc{
Here is a different rotation. This turns the graph so you can view it along the \texttt{math(y)}-axis.
}{
\spadpaste{rotate(vp, 0, -90)\bound{d3}\free{d1}}
}{
\epsffile[0 0 295 295]{../ps/ribbon2r.ps}
}\psXtc{There are many other things you can do. In fact, most everything you can do interactively using the \texttt{threedim{}} control panel (such as translating, zooming, resizing, coloring, perspective and lighting selections) can also be done directly by operations (see \texttt{downlink{"Graphics"}{ugGraphPage}} in Chapter 7\texttt{ignore{ugGraph} for more details}).

When you are done experimenting, say \texttt{reset(vp)} to restore the picture to its original position and settings.

Let’s add another ribbon to our picture---one for \texttt{math(x^3)}. Since \texttt{math(y)} ranges from \texttt{math(0)} to \texttt{math(1)} for the first ribbon, now let \texttt{math(y)} range from \texttt{math(1)} to \texttt{math(2)}. This puts the second ribbon next to the first one.

How do you add a second ribbon to the viewport? One method is to extract the ‘‘space’’ component from the viewport using the operation \texttt{spadfunFrom{subspace}{ThreeDimensionalViewport}}. You can think of the space component as the object inside the window (here, the ribbon).
Let’s call it \spad{sp}.
To add the second ribbon, you draw the second ribbon using the option \spad{space == sp}.

\xtc{
Extract the space component of \spad{vp}.
}\spadpaste{sp := subspace(vp)\bound{d5}\free{d1}}

\psXtc{
Add the ribbon for
\texht{x^3}{\spad{x**3}} alongside that for
\texht{x^2}{\spad{x**2}}.
}\graphpaste{vp := draw(x**3,x=-1..1,y=1..2,var2Steps==1, space==sp)\bound{d6}\free{d5}}
\epsffile[0 0 295 295]{../ps/ribbons.ps}

Unless you moved the original viewport, the new viewport covers
the old one.
You might want to check that the old object is still there by
moving the top window.

Let’s show quadrilateral polygon outlines on the ribbons and then
enclose the ribbons in a box.

\psXtc{
Show quadrilateral polygon outlines.
}\spadpaste{drawStyle(vp,"shade");outlineRender(vp,"on")\bound{d10}\free{d6}}
\epsffile[0 0 295 295]{../ps/ribbons2.ps}

Enclose the ribbons in a box.
\spadpaste{rotate(vp,20,-60); showRegion(vp,"on")\bound{d11}\free{d10}}
\epsffile[0 0 295 295]{../ps/ribbons2b.ps}

This process has become tedious!
If we had to add two or three more ribbons, we would have to
repeat the above steps several more times.
It is time to write an interpreter program to help us take care of
the details.

The above approach creates a new viewport for each additional ribbon. A better approach is to build one object composed of all ribbons before creating a viewport. To do this, use \spadfun{makeObject} rather than \spadfun{draw}. The operations have similar formats, but \spadfun{draw} returns a viewport and \spadfun{makeObject} returns a space object.

We now create a function \userfun{drawRibbons} of two arguments: \spad{flist}, a list of formulas for the ribbons you want to draw, and \spad{xrange}, the range over which you want them drawn. Using this function, you can just say

\begin{verbatim}
\verb|drawRibbons([x**2, x**3], x=-1..1)|
\end{verbatim}

to do all of the work required in the last section. Here is the \userfun{drawRibbons} program. Invoke your favorite editor and create a file called \texttt{\{bf ribbon.input\}} containing the following program.

\begin{Verbatim}
\tt 1. \ \ drawRibbons(flist, xrange) \ == \newline \tt 2. \ \ sp := createThreeSpace() \newline \tt 3. \ \ y0 := 0 \newline \tt 4. \ \ for \ \ f \ in \ flist \ repeat \newline \tt 5. \ \ \ \ makeObject(f, xrange, y=y0..y0+1, )
\end{verbatim}
Here are some remarks on the syntax used in the `\pspadfun{drawRibbons}` function (consult `\downlink{``User-Defined Functions, Macros and Rules''}{ugUserPage}` in Chapter 6 for more details). Unlike most other programming languages which use semicolons, parentheses, or `{\it begin}--{\it end}` brackets to delineate the structure of programs, the structure of an Axiom program is determined by indentation. The first line of the function definition always begins in column 1. All other lines of the function are indented with respect to the first line and form a `spadgloss{pile}` (see `\downlink{``Blocks''}{ugLangBlocksPage}` in Section 5.2).

The definition of `\userfun{drawRibbons}` consists of a pile of expressions to be executed one after another. Each expression of the pile is indented at the same level. Lines 4-7 designate one single expression: since lines 5-7 are indented with respect to the others, these lines are treated as a continuation of line 4. Also since lines 5 and 7 have the same indentation level, these lines designate a pile within the outer pile.

The last line of a pile usually gives the value returned by the pile. Here it is also the value returned by the function. Axiom knows this is the last line of the function because it is the last line of the file. In other cases, a new expression beginning in column one signals the end of a function.

The line `\spad{drawStyle(vp,"shade")}` is given after the viewport has been created to select the draw style. We have also used the `\spadfunFrom{zoom}{ThreeDimensionalViewport}` option. Without the zoom, the viewport region would be scaled equally in all three coordinate directions.

Let’s try the function `\userfun{drawRibbons}`.
First you must read the file to give Axiom the function definition.
Read the input file.

\spadpaste{)read ribbon \bound{s0}}

\graphpaste{drawRibbons([x**i for i in 1..5],x=-1..1) \free{s0}}

\epsffile[0 0 295 295]{../ps/ribbons5.ps}
Before leaving the ribbon example, we make two improvements. Normally, the color given to each point in the space is a function of its height within a bounding box. The points at the bottom of the box are red, those at the top are purple.

To change the normal coloring, you can give an option \spad{colorFunction == \text{\it function}}. When Axiom goes about displaying the data, it determines the range of colors used for all points within the box. Axiom then distributes these numbers uniformly over the number of hues. Here we use the simple color function \texht{$(x,y) \mapsto i$}{(x,y) \mapsto i} for the \eth{$i$} ribbon.

Also, we add an argument \spad{yrange} so you can give the range of \spad{y} occupied by the ribbons. For example, if the \spad{yrange} is given as \spad{y=0..1} and there are \smath{5} ribbons to be displayed, each ribbon would have width \smath{0.2} and would appear in the range \texht{$0 \leq y \leq 1$}{0 \leq y \leq 1}.

Refer to lines 4-9. Line 4 assigns to \spad{yVar} the variable part of the \spad{yrange} (after all, it need not be \spad{y}). Suppose that \spad{yrange} is given as \spad{t = a..b} where \spad{a} and \spad{b} have numerical values. Then line 5 assigns the value of \spad{a} to the variable \spad{y0}. Line 6 computes the width of the ribbon by dividing the difference of \spad{a} and \spad{b} by the number, \spad{num}, of ribbons. The result is assigned to the variable \spad{width}. Note that in the for-loop in line 7, we are iterating in parallel; it is not a nested loop.

\beginImportant

\noindent\tt
\begin{verbatim}
1. \ 	\drawRibbons(flist, \ xrange, \ yrange) \ == \newline
2. \ 	\sp\ := \ createThreeSpace()\newline
3. \ 	\num\ := \ #\ flist\newline
4. \ 	\yVar\ := \ variable\ yrange\newline
\end{verbatim}

\endImportant
Points, Lines, and Curves

—— ug10.HT ——

What you have seen so far is a high-level program using the graphics facility. We now turn to the more basic notions of points, lines, and curves in \texttt{threedim{}} graphs. These facilities use small floats (objects of type \texttt{DoubleFloat}) for data. Let us first give names to the small float values \texttt{smath{0}} and \texttt{smath{1}}.

\begin{verbatim}
\xtc{The small float 0.}
}\spadpaste{zero := 0.0@DFLOAT \bound{d1}}
\end{verbatim}
The small float 1.

The \texttt{@} sign means ‘of the type.’’ Thus \texttt{zero} is \texttt{0.0} of the type \texttt{DoubleFloat}.

Points can have four small float components: \texttt{x, y, z} coordinates and an optional color. A ‘‘curve’’ is simply a list of points connected by straight line segments.

Create the point \texttt{origin} with color zero, that is, the lowest color on the color map.

Create the point \texttt{unit} with color zero.

Create the curve (well, here, a line) from \texttt{origin} to \texttt{unit}.

We make this line segment into an arrow by adding an arrowhead. The arrowhead extends to, say, \texttt{p3} on the left, and to, say, \texttt{p4} on the right.

To describe an arrow, you tell Axiom to draw the two curves \texttt{\[p1, p2, p3\]} and \texttt{\[p2, p4\].}

We also decide through experimentation on values for \texttt{arrowScale}, the ratio of the size of the arrowhead to the stem of the arrow, and \texttt{arrowAngle}, the angle between the arrowhead and the arrow.

Invoke your favorite editor and create an input file called \texttt{\{bf arrows.input\}}. This input file first defines the values of %\texttt{\{spad\{origin\},\{spad\{unit\},} \texttt{\{spad\{arrowAngle\} and \{spad\{arrowScale\}, then defines the function \texttt{\{userfun\{makeArrow\}\{\texttt{\texttt{x}t\texttt{e}x\texttt{t}}\{\$p_1, p_2\}\}\{\texttt{\texttt{x}t\texttt{e}x\texttt{t}}\{\$p_1\}\texttt{ to }\texttt{\texttt{x}t\texttt{e}x\texttt{t}}\{\$p_2\}}\}

\beginImportant
\noindent
\beginImportant
\beginverbatim

A Bouquet of Arrows

Let's draw a 'bouquet' of arrows. Each arrow is identical. The arrowheads are uniformly placed on a circle parallel to the $xy$-plane. Thus the position of each arrow differs only by the angle $\theta$, $0 \leq \theta < 2\pi$, between the arrow and the $x$-axis on the $xy$-plane.

Our bouquet is rather special: each arrow has a different color (which won't be evident here, unfortunately). This is arranged by letting the color of each successive arrow be denoted by $\theta$. In this way, the color of arrows ranges from red to green to violet.

Here is a program to draw a bouquet of $n$ arrows.

\begin{verbatim}
1. drawBouquet(n,title) ==
2.  angle := 0.0
3.  sp := createThreeSpace()
4.  for i in 0..n-1 repeat
5.    start := point[0.0,0.0,0.0,angle]
6.    end := point[cos angle, sin angle, 1.0,angle]
7.    arrow := makeArrow(start,end)
8.    for a in makeArrow(start,end) repeat
9.      curve(sp,a)
10.    angle := angle + 2*%pi/n
11.  makeViewport3D(sp,title)
\end{verbatim}

Read the input file.
A bouquet of a dozen arrows.

\begin{verbatim}
(1) 0.20000000000000001
Type: DoubleFloat

(2) 2.8274333882308138
Type: DoubleFloat

Type: Void

Type: Void
\end{verbatim}

\end{verbatim}

\end{verbatim}

\end{verbatim}

\end{verbatim}

\end{verbatim}
We now put our arrows to good use drawing complex vector fields. These vector fields give a representation of complex-valued functions of complex variables. Consider a Cartesian coordinate grid of points \( (x, y) \) in the plane, and some complex-valued function \( f \) defined on this grid. At every point on this grid, compute the value of \( f(x + iy) \) and call it \( z \). Since \( z \) has both a real and imaginary value for a given \( (x,y) \) grid point, there are four dimensions to plot. What do we do? We represent the values of \( z \) by arrows planted at each grid point. Each arrow represents the value of \( z \) in polar coordinates \( (r, \theta) \). The length of the arrow is proportional to \( r \). Its direction is given by \( \theta \).

The code for drawing vector fields is in the file \{bf vectors.input\}. We discuss its contents from top to bottom.

Before showing you the code, we have two small matters to take care of. First, what if the function has large spikes, say, ones that go off to infinity? We define a variable \( \text{clipValue} \) for this purpose. When \( r \) exceeds the value of \( \text{clipValue} \), then the value of \( \text{clipValue} \) is used instead of that for \( r \). For convenience, we define a function \( \text{clipFun}(x) \) which uses \( \text{clipValue} \) to "clip" the value of \( x \).

\begin{verbatim}
1. clipValue : DFLOAT := 6
2. clipFun(x) == min(max(x,-clipValue),clipValue)
\end{verbatim}

Notice that we identify \( \text{clipValue} \) as a small float but do not declare the type of the function \( \text{clipFun} \). As it turns out, \( \text{clipFun} \) is called with a
small float value. This declaration ensures that \userfun{clipFun} never does a conversion when it is called.

The second matter concerns the possible ‘‘poles’’ of a function, the actual points where the spikes have infinite values. Axiom uses normal \spadtype{DoubleFloat} arithmetic which does not directly handle infinite values. If your function has poles, you must adjust your step size to avoid landing directly on them (Axiom calls \spadfun{error} when asked to divide a value by \axiom{0}, for example).

We set the variables \spad{realSteps} and \spad{imagSteps} to hold the number of steps taken in the real and imaginary directions, respectively. Most examples will have ranges centered around the origin. To avoid a pole at the origin, the number of points is taken to be odd.

\beginImportant
\noindent\tt 1. realSteps: \INT\ :=\ 25
\tt 2. imagSteps: \INT\ :=\ 25
\tt 3. )read arrows
\endImportant

Now define the function \userfun{drawComplexVectorField} to draw the arrows. It is good practice to declare the type of the main function in the file. This one declaration is usually sufficient to ensure that other lower-level functions are compiled with the correct types.

\beginImportant
\noindent\tt 4. \C:\ :=\ Complex\ DoubleFloat
\tt 5. \S:\ :=\ Segment\ DoubleFloat
\tt 6. \drawComplexVectorField:\ (\C\ ->\ \C,\ \S,\ \S\ ->\ \VIEW3D)
\endImportant

The first argument is a function mapping complex small floats into complex small floats. The second and third arguments give the range of real and imaginary values as segments like \spad{a..b}. The result is a \threeDim{} viewport. Here is the full function definition:

\beginImportant
\noindent
\beginImportant
As a first example, let us draw \spad{f(z) == sin(z)}. There is no need to create a user function: just pass the \spadfunFrom{sin}{Complex DoubleFloat} from \spadtype{Complex DoubleFloat}.

\end{verbatim}

\end{verbatim}

\end{verbatim}

\end{verbatim}

\end{verbatim}

\end{verbatim}
Here is another way to graph a complex function of complex arguments. For each complex value \( z \), compute \( f(z) \), again expressing the value in polar coordinates \( (r, \theta) \). We draw the complex valued function, again considering the \( (x, y) \)-plane as the complex plane, using \( r \) as the height (or \( z \)-coordinate) and \( \theta \) as the color. This is a standard plot---we learned how to do this in Chapter 7---but here we write a new program to illustrate the creation of polygon meshes, or grids.

Call this function \( \text{drawComplex} \).

It displays the points using the ‘‘mesh’’ of points. The function definition is in three parts.

```
\beginImportant
\noindent
\begin{verbatim}
1. \text{drawComplex: (C -> C, S, S) -> VIEW3D}
2. \text{drawComplex(f, realRange, imagRange) ==}
3. \hspace{1em} \text{\begin{verbatim}
4. \hspace{1em} delReal := (hi(realRange)-lo(realRange))/realSteps}
5. \hspace{1em} delImag := (hi(imagRange)-lo(imagRange))/imagSteps}
6. \hspace{1em} \text{llp:List List Point DFLOAT := []}
7. \hspace{1em} \end{verbatim}
8. \hspace{1em} \end{verbatim}
9. \hspace{1em} \text{\begin{verbatim}
10. \hspace{2em} \text{real := lo(realRange)}
11. \hspace{2em} for i in 1..realSteps+1 \text{ repeat}
12. \hspace{3em} imag := lo(imagRange)}
\end{verbatim}
\end{verbatim}
\endImportant
```

Variables \spad{delReal} and \spad{delImag} give the step sizes along the real and imaginary directions as computed by the values of the global variables \spad{realSteps} and \spad{imagSteps}. The mesh is represented by a list of lists of points \spad{llp}, initially empty. Now \spad{[]} alone is ambiguous, so to set this initial value you have to tell Axiom what type of empty list it is. Next comes the loop which builds \spad{llp}. 
The code consists of both an inner and outer loop. Each pass through the inner loop adds one list $\text{lp}$ of points to the list of lists of points $\text{llp}$. The elements of $\text{lp}$ are collected in reverse order.

\begin{verbatim}
4. \ \ \ \ \ \ \ \ lp := [ ] \$(List \ Point \ DFLOAT)\newline
5. \ \ \ \ \ \ \ for \ j \ in \ 1..imagSteps+1 \ repeat\newline
6. \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ z := \ f \ complex(real,imag)\newline
7. \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ pt := point\newline
\ [real,imag,\ clipFun \ sqrt \ norm \ z,\ ]\newline
8. \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ argument \ z]\newline
9. \ \ \ \ \ \ \ \ lp := cons(pt,lp)\newline
10. \ \ \ \ \ \ \ \ imag := imag + delImag\newline
11. \ \ \ \ \ \ \ \ real := real + delReal\newline
12. \ \ \ \ \ \ \ \ llp := cons(lp, llp)\newline
\end{verbatim}

The operation $\text{spadfun(mesh)}$ then creates an object of type $\text{spadtype(ThreeSpace(DoubleFloat))}$ from the list of lists of points. This is then passed to $\text{spadfun(makeViewport3D)}$ to display the image.

Now add this function directly to your $\textbf{vectors.input}$ file and re-read the file using $\text{spad()}$read vectors). We try $\text{userfun(drawComplex)}$ using a user-defined function $\text{spad(f)}$.

\begin{verbatim}
13. \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ makeViewport3D(mesh(llp), "Complex \ Function")\newline
\end{verbatim}

Read the file.

Functions Producing Functions

⇒ “notitle” (ugUserMakePage) 10 on page 1889
— ug10.ht —

In \downlink{‘Making Functions from Objects’}{ugUserMakePage} in Section 6.14\ignore{ugUserMake}, you learned how to use the operation \spadfun{function} to create a function from symbolic formulas. Here we introduce a similar operation which not only creates functions, but functions from functions.

The facility we need is provided by the package \spadtype{MakeUnaryCompiledFunction(E,S,T)}. This package produces a unary (one-argument) compiled function from some symbolic data generated by a previous computation.\footnote{\spadtype{MakeBinaryCompiledFunction} is available for binary functions.} The \spad{E} tells where the symbolic data comes from; the \spad{S} and \spad{T} give Axiom the source and target type of the function, respectively. The compiled function produced has type \spad{\spad{S}\to\spad{T}}. To produce a compiled function with definition \spad{p(x) == expr}, call \spad{compiledFunction(expr, x)} from this package. The function you get has no name. You must to assign the function to the variable \spad{p} to give it that name. %
\xtc{ Do some computation. }{ \spadpaste{(x+1/3)**5\bound{p1}} }
\text{Convert this to an anonymous function of } \text{\texttt{spad}}(x). \text{ Assign it to the variable } \text{\texttt{spad}}(p) \text{ to give the function a name. } \text{\{ \text{\texttt{spadpaste}}(p \text{ := } \text{\texttt{compiledFunction}}(\%,x)\text{\$MakeUnaryCompiledFunction}(\text{\texttt{POLY FRAC INT}},\text{\texttt{DFLOAT}},\text{\texttt{DFLOAT}})\text{\bound{p2}}\text{\free{p1}}) \}} \text{ Apply the function. } \text{\{ \text{\texttt{spadpaste}}(p(\text{\texttt{sin(1.3)})})\text{\bound{p3}}\text{\free{p2}}\}} \\

Automatic Newton Iteration Formulas

We resume our continuing saga of arrows and complex functions. Suppose we want to investigate the behavior of Newton’s iteration function in the complex plane. Given a function \( f \), we want to find the complex values \( z \) such that \( f(z) = 0 \).

The first step is to produce a Newton iteration formula for a given \( f \):

\[
\text{\texttt{x(n+1) = x(n) - f(x(n))/f'(x(n))}.}
\]

We represent this formula by a function \( g \) that performs the computation on the right-hand side, that is,

\[
\text{\texttt{x(n+1) = g(x(n))}}\texttt{.}
\]

The type \( \text{\texttt{Expression Integer}} \) (abbreviated \( \text{\texttt{EXPR INT}} \)) is used to represent general symbolic expressions in Axiom.

To make our facility as general as possible, we assume \( \text{\texttt{f}} \) has this type. Given \( \text{\texttt{f}} \), we want to produce a Newton iteration function \( \text{\texttt{g}} \) which, given a complex point \( x(n) \), delivers the next Newton iteration point \( x(n+1) \).
This time we write an input file called `newton.input`.

We need to import \spadtype{MakeUnaryCompiledFunction} (discussed in the last section), call it with appropriate types, and then define the function \spad{newtonStep} which references it.

Here is the function \spad{newtonStep}:

\beginImportant

\beginverbatim
C := Complex DoubleFloat
complexFunPack:=MakeUnaryCompiledFunction(EXPR INT,C,C)
newtonStep(f) ==
fun := complexNumericFunction f
deriv := complexDerivativeFunction(f,1)
(x:C):C +-> x - fun(x)/deriv(x)

complexNumericFunction f ==
v := theVariableIn f
compiledFunction(f,v)\$complexFunPack

complexDerivativeFunction(f,n) ==
v := theVariableIn f
df := D(f,v,n)
compiledFunction(df,v)\$complexFunPack

theVariableIn f ==
vl := variables f
nv := \# vl
nv > 1 => error "Expression\ is\ not\ univariate."

theVariableIn f == \ x
first vl\$endImportant
\endverbatim

Do you see what is going on here?

A formula \spad{f} is passed into the function \userfun{newtonStep}. First, the function turns \spad{f} into a compiled program mapping complex numbers into complex numbers. Next, it does the same thing for the derivative of \spad{f}. Finally, it returns a function which computes a single step of Newton’s iteration.

The function \userfun{complexNumericFunction} extracts the variable from the expression \spad{f} and then turns \spad{f} into a function which maps complex numbers into complex numbers. The function \userfun{complexDerivativeFunction} does the same thing for the derivative of \spad{f}. The function \userfun{theVariableIn}
extracts the variable from the expression \( \text{spad}(f) \), calling the function \( \text{spad\texttt{fun}}(\text{error}) \) if \( \text{spad}(f) \) has more than one variable.
It returns the dummy variable \( \text{spad}(x) \) if \( \text{spad}(f) \) has no variables.

Let’s now apply \( \text{userfun}(\text{newtonStep}) \) to the formula for computing cube roots of two.

\% \xtc{
Read the input file with the definitions.
}\{
\spadpaste{)read newton\bound{n1}}
\}
}\xtc{
\spadpaste{)read vectors \bound{n1a}}
\}
\xtc{
The cube root of two.
}\{
\spadpaste{f := x**3 - 2\bound{n2}\free{n1 n1a}}
\}
\xtc{
Get Newton’s iteration formula.
}\{
\spadpaste{g := newtonStep f\bound{n3}\free{n2}}
\}
\xtc{
Let \( \text{spad}(a) \) denote the result of applying Newton’s iteration once to the complex number \( \text{spad}(1 + \text{\%i}) \).
}\{
\spadpaste{a := g(1.0 + \text{\%i})\bound{n4}\free{n3}}
\}
\xtc{
Now apply it repeatedly. How fast does it converge?
}\{
\spadpaste{[(a := g(a)) for i in 1..}\bound{n5}\free{n4}}
\}
\xtc{
Check the accuracy of the last iterate.
}\{
\spadpaste{a**3\bound{n6}\free{n5}}
\}

In \downlink{`MappingPackage1'}{MappingPackageOneXmpPage}
\ignore{MappingPackage1},
we show how functions can be manipulated as objects in Axiom. A useful operation to consider here is \( \text{spad\texttt{op}}(*) \), which means composition. For example \( \text{spad}(g*g) \) causes the Newton iteration formula to be applied twice. Correspondingly, \( \text{spad}(g**n) \) means to
apply the iteration formula \spad{n} times.

\xtc{
Apply \spad{g} twice to the point \spad{1 + \%i}. 
}{
\spadpaste{(g*g) (1.0 + \%i)\bound{n10}\free{n3}} 
}
\xtc{
Apply \spad{g} 11 times.
}{
\spadpaste{(g**11) (1.0 + \%i)\bound{n11}\free{n10}} 
}

Look now at the vector field and surface generated 
after two steps of Newton's formula for the cube root of two. 
The poles in these pictures represent bad starting values, and the 
flat areas are the regions of convergence to the three roots.

\begin{page}{ugPackagesPage} {11. Packages}
\beginscroll

Packages provide the bulk of Axiom’s algorithmic library, from numeric packages for computing special functions to symbolic facilities for differential equations, symbolic integration, and limits.

In \downlink{‘Interactive Programming’}{ugIntProgPage} in Chapter 10\ignore{ugIntProg}, we developed several useful functions for drawing vector fields and complex functions. We now
show you how you can add these functions to the Axiom library to make them available for general use.

The way we created the functions in Chapter 10 of Axiom is typical of how you, as an advanced Axiom user, may interact with Axiom. You have an application. You go to your editor and create an input file defining some functions for the application. Then you run the file and try the functions. Once you get them all to work, you will often want to extend them, add new features, perhaps write additional functions.

Eventually, when you have a useful set of functions for your application, you may want to add them to your local Axiom library. To do this, you embed these function definitions in a package and add that package to the library.

To introduce new packages, categories, and domains into the system, you need to use the Axiom compiler to convert the constructors into executable machine code. An existing compiler in Axiom is available on an ‘as-is’ basis. A new, faster compiler will be available in version 2.0 of Axiom.

---

Names, Abbreviations, and File Structure
Each package has a name and an abbreviation. For a package of the complex draw functions from Interactive Programming in Chapter 10, we choose the name DrawComplex and abbreviation DRAWCX. An abbreviation can be any string of between two and seven capital letters and digits, beginning with a letter. See Section 2.5.5 for more information. To be sure that you have not chosen a name or abbreviation already used by the system, issue the system command \spadcmd{)show} for both the name and the abbreviation.

Once you have named the package and its abbreviation, you can choose any new filename you like with extension ''``\spadFileExt{}```'' to hold the definition of your package. We choose the name \spadFileExt{drawpak}. If your application involves more than one package, you can put them all in the same file. Axiom assumes no relationship between the name of a library file, and the name or abbreviation of a package.

Near the top of the ''``\spadFileExt{}```'' file, list all the abbreviations for the packages using \spadcmd{)abbrev}, each command beginning in column one. Macros giving names to Axiom expressions can also be placed near the top of the file. The macros are only usable from their point of definition until the end of the file.

Consider the definition of \nonLibAxiomType{DrawComplex} in Figure \ref{fig-pak-cdraw}. After the macro definition

\begin{verbatim}
S ==> Segment DoubleFloat
\end{verbatim}

the name \spad{S} can be used in the file as a shorthand for \axiomType{Segment DoubleFloat}. The interpreter also allows \spad{macro} for macro definitions. The abbreviation command for the package

\begin{verbatim}
...
Syntax
Abstract Datatypes

A constructor as defined in Axiom is called an \spadgloss{abstract
datatype} in the computer science literature. Abstract datatypes separate `specification' (what operations are provided) from `implementation' (how the operations are implemented). The \tt{Exports} (specification) part of a constructor is said to be `public' (it provides the user interface to the package) whereas the \tt{Implementation} part is `private' (information here is effectively hidden---programs cannot take advantage of it).

The \tt{Exports} part specifies what operations the package provides to users. As an author of a package, you must ensure that the \tt{Implementation} part provides a function for each operation in the \tt{Exports} part.\footnote{The \spadtype{DrawComplex} package enhances the facility described in \downlink{``Drawing Complex Functions''}{ugIntProgCompFunsPage} in Chapter 10.7\ignore{ugIntProgCompFuns} by allowing a complex function to have arrows emanating from the surface to indicate the direction of the complex argument.}

An important difference between interactive programming and the use of packages is in the handling of global variables such as \axiom{realSteps} and \axiom{imagSteps}. In interactive programming, you simply change the values of variables by \spadgloss{assignment}. With packages, such variables are local to the package---their values can only be set using functions exported by the package. In our example package, we provide two functions \fakeAxiomFun{setRealSteps} and \fakeAxiomFun{setImagSteps} for this purpose.

Another local variable is \axiom{clipValue} which can be changed using
the exported operation \fakeAxiomFun{setClipValue}. This value is referenced by the internal function \fakeAxiomFun{clipFun} that decides whether to use the computed value of the function at a point or, if the magnitude of that value is too large, the value assigned to \axiom{clipValue} (with the appropriate sign).

\autobuttons
\end{page}

---

Capsules

— ug11.ht —

\begin{page}{ugPackagesCapsulesPage}{11.4. Capsules}
\begainscroll
%
The part to the right of {\tt add} in the {\tt Implementation} \spadkey{add} part of the definition is called a {\spadgloss{capsule}}. The purpose of a capsule is:
\indent{4}
\beginitems
\item[-] to define a function for each exported operation, and
\item[-] to define a {\spadgloss{local environment}} for these functions to run.
\enditems
\indent{0}

What is a local environment?
First, what is an environment?
Think of the capsule as an input file that Axiom reads from top to bottom.
Think of the input file as having a \axiom{)clear all} at the top so that initially no variables or functions are defined.
When this file is read, variables such as \axiom{realSteps} and \axiom{arrowSize} in \nonLibAxiomType{DrawComplex} are set to initial values. Also, all the functions defined in the capsule are compiled. These include those that are exported (like \axiom{drawComplex}), and those that are not (like \axiom{makeArrow}).
At the end, you get a set of name-value pairs: variable names (like \axiom{realSteps} and \axiom{arrowSize}) are paired with assigned values, while operation names (like \axiom{drawComplex} and \axiom{makeArrow}) are paired with function values.
This set of name-value pairs is called an \spadgloss{environment}. Actually, we call this environment the ‘‘initial environment’’ of a package: it is the environment that exists immediately after the package is first built. Afterwards, functions of this capsule can access or reset a variable in the environment. The environment is called \it{local} since any changes to the value of a variable in this environment can be seen \it{only} by these functions.

Only the functions from the package can change the variables in the local environment. When two functions are called successively from a package, any changes caused by the first function called are seen by the second.

Since the environment is local to the package, its names don’t get mixed up with others in the system or your workspace. If you happen to have a variable called \texttt{realSteps} in your workspace, it does not affect what the \nonLibAxiomType{DrawComplex} functions do in any way.

The functions in a package are compiled into machine code. Unlike function definitions in input files that may be compiled repeatedly as you use them with varying argument types, functions in packages have a unique type (generally parameterized by the argument parameters of a package) and a unique compilation residing on disk.

The capsule itself is turned into a compiled function. This so-called \it{capsule function} is what builds the initial environment spoken of above. If the package has arguments (see below), then each call to the package constructor with a distinct pair of arguments builds a distinct package, each with its own local environment.

\autobuttons
\end{page}

\input{ugPackagesInputFilesPage}

Input Files vs. Packages

— ug11.ht —

\input{ugPackagesInputFilesPage}

\% A good question at this point would be
\% ‘‘Is writing a package more difficult than writing an input file?’’
The programs in input files are designed for flexibility and ease-of-use. Axiom can usually work out all of your types as it reads your program and does the computations you request. Let’s say that you define a one-argument function without giving its type. When you first apply the function to a value, this value is understood by Axiom as identifying the type for the argument parameter. Most of the time Axiom goes through the body of your function and figures out the target type that you have in mind. Axiom sometimes fails to get it right. Then—and only then—do you need a declaration to tell Axiom what type you want.

Input files are usually written to be read by Axiom—and by you. Without suitable documentation and declarations, your input files are likely incomprehensible to a colleague—and to you some months later!

Packages are designed for legibility, as well as run-time efficiency. There are few new concepts you need to learn to write packages. Rather, you just have to be explicit about types and type conversions. The types of all functions are pre-declared so that Axiom—and the reader—knows precisely what types of arguments can be passed to and from the functions (certainly you don’t want a colleague to guess or to have to work this out from context!). The types of local variables are also declared. Type conversions are explicit, never automatic.

In summary, packages are more tedious to write than input files. When writing input files, you can casually go ahead, giving some facts now, leaving others for later. Writing packages requires forethought, care and discipline.

Compiling Packages

--- ug11.ht ---

\begin{page}{ugPackagesPackagesPage}{11.6. Compiling Packages}
Once you have defined the package \nonLibAxiomType{DrawComplex}, you need to compile and test it. To compile the package, issue the system command \spadcmd{(compile drawpak)}. Axiom reads the file \spadFileExt{drawpak} and compiles its contents into machine binary. If all goes well, the file \spadFileExt{DRAWCX} is created in your local directory for the package. To test the package, you must load the package before trying an operation.

\nullXtc{
  Compile the package.
}
\spadpaste{)compile drawpak}

\indentrel{-3}
The power of packages becomes evident when packages have parameters. Usually these parameters are domains and the exported operations have types involving these parameters.

In \downlink{‘Using Types and Modes’}{ugTypesPage} in Chapter 2\ignore{ugTypes}, you learned that categories denote classes of domains. Although we cover this notion in detail in the next chapter, we now give you a sneak preview of its usefulness.

In \downlink{‘Functions Defined with Blocks’}{ugUserBlocksPage} in Section 6.15\ignore{ugUserBlocks}, we defined functions \axiom{bubbleSort(m)} and \axiom{insertionSort(m)} to sort a list of integers. If you look at the code for these functions, you see that they may be used to sort \{\it any\} structure \axiom{m} with the right properties. Also, the functions can be used to sort lists of \{\it any\} elements---not just integers. Let us now recall the code for \axiom{bubbleSort}.

\begin{verbatim}
bubbleSort(m) ==
  n := #m
  for i in 1..(n-1) repeat
    for j in n..(i+1) by -1 repeat
      if m.j < m.(j-1) then swap!(m,j,j-1)
  m
\end{verbatim}

What properties of ‘‘lists of integers’’ are assumed by the sorting algorithm? In the first line, the operation \spadfun{\#} computes the
maximum index of the list. The first obvious property is that \axiom{m} must have a finite number of elements. In Axiom, this is done by your telling Axiom that \axiom{m} has the `'attribute'' \spadatt{finiteAggregate}. An \spadgloss{attribute} is a property that a domain either has or does not have. As we show later in \downlink{``Attributes''}{ugCategoriesAttributesPage} in Section 12.9\ignore{ugCategoriesAttributes}, programs can query domains as to the presence or absence of an attribute.

The operation \spadfunX{swap} swaps elements of \axiom{m}. Using \Browse{}, you find that \spadfunX{swap} requires its elements to come from a domain of category \axiom{IndexedAggregate} with attribute \spadatt{shallowlyMutable}. This attribute means that you can change the internal components of \axiom{m} without changing its external structure. Shallowly-mutable data structures include lists, streams, one- and two-dimensional arrays, vectors, and matrices.

The category \axiom{IndexedAggregate} designates the class of aggregates whose elements can be accessed by the notation \axiom{m.s} for suitable selectors \axiom{s}. The category \axiom{IndexedAggregate} takes two arguments: \axiom{Index}, a domain of selectors for the aggregate, and \axiom{Entry}, a domain of entries for the aggregate. Since the sort functions access elements by integers, we must choose \axiom{Index = Integer}. The most general class of domains for which \axiom{bubbleSort} and \axiom{insertionSort} are defined are those of category \axiom{IndexedAggregate(Integer,Entry)} with the two attributes \spadatt{shallowlyMutable} and \spadatt{finiteAggregate}.

Using \Browse{}, you can also discover that Axiom has many kinds of domains with attribute \spadatt{shallowlyMutable}. Those of class \axiom{IndexedAggregate(Integer,Entry)} include \axiom{Bits}, \axiom{FlexibleArray}, \axiom{OneDimensionalArray}, \axiom{List}, \axiom{String}, and \axiom{Vector}, and also \axiom{HashTable} and \axiom{EqTable} with integer keys. Although you may never want to sort all such structures, we nonetheless demonstrate Axiom’s ability to do so.

Another requirement is that \nonLibAxiomType{Entry} has an operation \axiomOp{<}. One way to get this operation is to assume that \nonLibAxiomType{Entry} has category \axiom{OrderedSet}. By definition, will then export a \axiomOp{<} operation. A more general approach is to allow any comparison function \axiom{f} to be used for sorting. This function will be passed as an argument to the sorting functions.
Our sorting package then takes two arguments: a domain \(\mathsf{S}\) of objects of \{\text{it any}\} type, and a domain \(\mathsf{A}\), an aggregate of type \(\mathsf{IndexedAggregate}\{\mathsf{Integer}, \mathsf{S}\}\) with the above two attributes. Here is its definition using what are close to the original definitions of \(\mathsf{bubbleSort}\) and \(\mathsf{insertionSort}\) for sorting lists of integers. The symbol \(\mathsf{Syntax}\{!\}\) is added to the ends of the operation names. This uniform naming convention is used for Axiom operation names that destructively change one or more of their arguments.

\beginImportant

\begin{verbatim}
1. \SortPackage(S,A) : Exports == Implementation where
2.   S : Object
3.   A : IndexedAggregate(Integer,S) with (finiteAggregate; shallowlyMutable)
4.   Exports == with
5.     bubbleSort! : (A, (S,S) -> Boolean) -> A
6.     insertionSort! : (A, (S,S) -> Boolean) -> A
7. Implementation == add
8.   bubbleSort!(m,f) ==
9.     n := #m
10.    for i in 1..(n-1) repeat
11.       for j in n..(i+1) by -1 repeat
12.          if f(m.j,m.(j-1)) then swap!(m,j,j-1)
13.     m
14.   insertionSort!(m,f) ==
15.     for i in 1..#m repeat
16.       j := i
17.       while j > 1 and f(m.j,m.(j-1)) repeat
18.         swap!(m,j,j-1)
19.       j := (j - 1) pretend PositiveInteger
20.     m
\end{verbatim}
\endImportant

\end{page}
When packages have parameters, you can say that an operation is or is not exported depending on the values of those parameters. When the domain of objects $\text{axiom}(S)$ has an $\text{axiomOp}<$ operation, we can supply one-argument versions of $\text{axiom(bubbleSort)}$ and $\text{axiom(insertionSort)}$ which use this operation for sorting. The presence of the operation $\text{axiomOp}<$ is guaranteed when $\text{axiom}(S)$ is an ordered set.

\beginImportant
\noindent
\tt 1. Exports == with\newline\tt 2. \hspace{1cm} bubbleSort! : (A,(S,S) -> Boolean) -> A\newline\tt 3. \hspace{1cm} insertionSort! : (A,(S,S) -> Boolean) -> A\newline\tt 4. \hspace{1cm} if S has OrderedSet then\newline\tt 5. \hspace{2cm} bubbleSort! : A -> A\newline\tt 6. \hspace{2cm} insertionSort! : A -> A\newline\endImportant

In addition to exporting the one-argument sort operations conditionally, we must provide conditional definitions for the operations in the \tt Implementation part. This is easy: just have the one-argument functions call the corresponding two-argument functions with the operation $\text{axiomOp}<$.}

\beginImportant
\noindent
\tt 1. Implementation == add\newline\tt 2. \hspace{1cm} ...\newline\tt 3. \hspace{1cm} if S has OrderedSet then\newline\tt 4. \hspace{2cm} bubbleSort!(m) == bubbleSort!(m,<\$S)\newline\tt 5. \hspace{1cm} 

In Section 6.15, we give an alternative definition of \fakeAxiomFun{bubbleSort} using \spadfun{first}{List} and \spadfun{rest}{List} that is more efficient for a list (for which access to any element requires traversing the list from its first node). To implement a more efficient algorithm for lists, we need the operation \spadfun{setelt} which allows us to destructively change the \spadfun{first} and \spadfun{rest} of a list. Using \Browse{}, you find that these operations come from category \axiomType{UnaryRecursiveAggregate}. Several aggregate types are unary recursive aggregates including those of \axiomType{List} and \axiomType{AssociationList}. We provide two different implementations for \fakeAxiomFun{bubbleSort!} and \fakeAxiomFun{insertionSort!}: one for list-like structures, another for array-like structures.

\beginImportant

\noindent

\beginverbatim
1. Implementation \==\ add
2. \ldots
3. if \ A\ has\ UnaryRecursiveAggregate(S)\ then
4. bubbleSort!(m,fn) \==\ empty?\ m \Rightarrow m
5. l := m
6. while not empty? (r := l.rest) repeat
7. r := bubbleSort!(r,fn)
8. x := l.first
9. if fn(r.first, x) then
10. r.first := x
11. l.first := r.first
12. l.rest := r
13. l := l.rest
14. insertionSort!(m,fn) \==\ ...
\endverbatim

\endImportant

The ordering of definitions is important. The standard definitions come first and then the predicate

\verbatim
A has UnaryRecursiveAggregate(S)
\endverbatim

is evaluated.
If \tt{true}, the special definitions cover up the standard ones.

Another equivalent way to write the capsule is to use an \axiom{if-then-else} expression:
\spadkey{if}

\beginImportant
\noindent
\tt{1. \if A \then \nnl 2. ... \nnl 3. \else \nnl 4. ... \nnl \endImportant
\endscroll
\begin{verbatim}
)abbrev package SORTPAK SortPackage

)
expose SORTPAK

)compile sortpak

\end{verbatim}
\xtc{Expose the constructor.}
\xtc{You are then ready to begin testing.}
\spadpaste{)expose SORTPAK}
\spadpaste{l := [1,7,4,2,11,-7,3,2]}

\section*{Testing}

\Rightarrow "notitle" (EqTableXmpPage) 3.26 on page 386

-- ug11.ht --

\begin{verbatim}
)abbrev package SORTPAK SortPackage

)
expose SORTPAK

)compile sortpak

\end{verbatim}

Once you have written the package, embed it in a file, for example, \tt{sortpak.spadFileExt{}}. Be sure to include an \axiom{)abbrev} command at the top of the file:
\begin{verbatim}
)abbrev package SORTPAK SortPackage
\end{verbatim}

Now compile the file (using \spadcmd{)compile sortpak\spadFileExt{}}).
\xtc{Expose the constructor.}
\xtc{You are then ready to begin testing.}
\spadpaste{)expose SORTPAK}
\spadpaste{l := [1,7,4,2,11,-7,3,2]}
Since the integers are an ordered set, a one-argument operation will do.
\spadpaste{bubbleSort!(l)}

Re-sort it using "greater than."
\spadpaste{bubbleSort!(l,(x,y) => x > y)}

Now sort it again using \axiomOp{<} on integers.
\spadpaste{bubbleSort!(l, <\$Integer)}

A string is an aggregate of characters so we can sort them as well.
\spadpaste{bubbleSort! "Mathematical Sciences"}

Is \axiomOp{<} defined on booleans?
\spadpaste{false < true}

Good! Create a bit string representing ten consecutive boolean values \axiom{true}.
\spadpaste{u : Bits := new(10,true)}

Set bits 3 through 5 to \axiom{false}, then display the result.
\spadpaste{u(3..5) := false; u}

Now sort these booleans.
\spadpaste{bubbleSort! u}

Create an "eq-table" (see \downlink{EqTable}{EqTableXmpPage}) a table having integers as keys and strings as values.
\spadpaste{t : EqTable(Integer,String) := table()}
Give the table a first entry.
}\spad{t.1 := "robert"}
\xtc{And a second.}
}\spad{t.2 := "richard"}
\xtc{What does the table look like?}
}\spad{t}
\xtc{Now sort it.}
}\spad{bubbleSort! t}

\end{scroll}

How Packages Work

Recall that packages as abstract datatypes are compiled independently and put into the library. The curious reader may ask: ‘’How is the interpreter able to find an operation such as \fakeAxiomFun{bubbleSort!}? Also, how is a single compiled function such as \fakeAxiomFun{bubbleSort!} able to sort data of different types?’’

After the interpreter loads the package \nonLibAxiomType{SortPackage}, the four operations from the package become known to the interpreter. Each of these operations is expressed as a \(\text{it modemap}\) in which the type of the operation is written in terms of symbolic domains.

\nullXtc{
See the modemaps for \fakeAxiomFun{bubbleSort!}.
}\{\spadpaste{)display op bubbleSort!}\}
\begin{verbatim}
There are 2 exposed functions called bubbleSort! :

[1] D1 -> D1 from SortPackage(D2,D1)
    if D2 has ORDSET and D2 has OBJECT and D1 has
    IndexedAggregate(Integer, D2) with
\end{verbatim}
finiteAggregate
shallowlyMutable

\[ (D_1, ((D_3, D_3) \to \text{Boolean})) \to D_1 \text{ from SortPackage}(D_3, D_1) \]
if \( D_3 \) has \text{OBJECT} and \( D_1 \) has
\text{IndexedAggregate}(\text{Integer}, D_3) \text{ with }
finiteAggregate
shallowlyMutable

What happens if you ask for \texttt{bubbleSort!([1,-5,3])}?
There is a unique modemap for an operation named \texttt{bubbleSort!} with one argument.
Since \texttt{[1,-5,3]} is a list of integers, the symbolic domain \texttt{D_1} is defined as \texttt{List(Integer)}.
For some operation to apply, it must satisfy the predicate for some \texttt{D_2}.
What \texttt{D_2}?
The third expression of the \texttt{and} requires \{tt D_1 has
\text{IndexedAggregate(Integer, D_2) with} two attributes.
So the interpreter searches for an \texttt{IndexedAggregate} among the ancestors of \texttt{List(Integer)} (see
\texttt{Hierarchies}) in Section 12.4. It finds one: \texttt{IndexedAggregate(Integer, Integer)}. The interpreter tries
defining \texttt{D_2} as \texttt{Integer}. After substituting for
\texttt{D_1} and \texttt{D_2}, the predicate evaluates to \texttt{true}.
An applicable operation has been found!

Now \texttt{Axiom} builds the package \texttt{SortPackage(List(Integer), Integer)}. According to its definition, this package exports the
required operation: \texttt{bubbleSort!}: \texttt{spadsig{List Integer}{List Integer}}. The interpreter then asks the package for a
function implementing this operation. The package gets all the
functions it needs (for example, \texttt{rest} and \texttt{swap})
from the appropriate domains and then it returns a
\texttt{bubbleSort!} to the interpreter together with the local
environment for \texttt{bubbleSort!}. The interpreter applies
the function to the argument \texttt{[1,-5,3]}. The
\texttt{bubbleSort!} function is executed in its local
environment and produces the result.

Chapter 15

Users Guide Chapter 12 (ug12.ht)

Categories

\begin{page}{ugCategoriesPage}{12. Categories}
\beginscroll

This chapter unravels the mysteries of categories---what they are, how they are related to domains and packages, how they are defined in Axiom, and how you can extend the system to include new categories of your own.

We assume that you have read the introductory material on domains and
categories in
\[\text{``Domain Constructors''}\]\cite{ugTypesBasicDomainConsPage}
in Section 2.1.1\cite{ugTypesBasicDomainConsPage}. There
you learned that the notion of packages covered in the previous
chapter are special cases of domains. While this is in fact the case,
it is useful here to regard domains as distinct from packages.

Think of a domain as a datatype, a collection of objects (the objects
of the domain). From your ‘‘sneak preview’’ in the previous chapter,
you might conclude that categories are simply named clusters of
operations exported by domains. As it turns out, categories have a
much deeper meaning. Categories are fundamental to the design of
Axiom. They control the interactions between domains and algorithmic
packages, and, in fact, between all the components of Axiom.

Categories form hierarchies as shown on the inside cover pages of this
book. The inside front-cover pages illustrate the basic algebraic
hierarchy of the Axiom programming language. The inside back-cover
pages show the hierarchy for data structures.

Think of the category structures of Axiom as a foundation for a city
on which superstructures (domains) are built. The algebraic
hierarchy, for example, serves as a foundation for constructive
mathematical algorithms embedded in the domains of Axiom. Once in
place, domains can be constructed, either independently or from one
another.

Superstructures are built for quality---domains are compiled into
machine code for run-time efficiency. You can extend the foundation
in directions beyond the space directly beneath the superstructures,
then extend selected superstructures to cover the space. Because of
the compilation strategy, changing components of the foundation
generally means that the existing superstructures (domains) built on
the changed parts of the foundation (categories) have to be
rebuilt—that is, recompiled.

Before delving into some of the interesting facts about categories,
let’s see how you define them in Axiom.

Definitions

A category is defined by a function with exactly the same format as any other function in Axiom.

The definition of a category has the syntax:
\centerline{{\it CategoryForm} : {\tt Category\quad{}==\quad{}}}
\centerline{{\it Extensions} {\tt [ with} {\it Exports} {\tt ]}}

The brackets {\tt [ ]} here indicate optionality.

The first example of a category definition is \spadtype{SetCategory},
the most basic of the algebraic categories in Axiom.

The definition starts off with the name of the category (\spadtype{SetCategory}); this is always in column one in the source file.
All parts of a category definition are then indented with respect to this first line.

In \downlink{"Using Types and Modes"}{ugTypesPage} in Chapter 2\ignore{ugTypes}, we talked about \spadtype{Ring} as denoting the class of all domains that are rings, in short, the class of all rings. While this is the usual naming convention in Axiom, it is also common to use the word ‘‘Category’’ at the end of a category name for clarity. The interpretation of the name \spadtype{SetCategory} is, then, ‘‘the category of all domains that are (mathematical) sets.’’

The name \spadtype{SetCategory} is followed in the definition by its formal parameters enclosed in parentheses \spadSyntax{()}. Here there are no parameters. As required, the type of the result of this category function is the distinguished name \lisp{Category}.

Then comes the \spadSyntax{==}. As usual, what appears to the right of the \spadSyntax{==} is a definition, here, a category definition. A category definition always has two parts separated by the reserved word \spadkey{with}.

The first part tells what categories the category extends. Here, the category extends two categories: \spadtype{Type}, the category of all domains, and \spadtype{CoercibleTo(OutputForm)}. \%\footnote{\spadtype{CoercibleTo(OutputForm)} can also be written (and is written in the definition above) without parentheses.}

The operation \spad{Join} is a system-defined operation that \spadkey{Join} forms a single category from two or more other categories.

Every category other than \spadtype{Type} is an extension of some other category. If, for example, \spadtype{SetCategory} extended only the category \spadtype{Type}, the definition here would read ‘‘{\tt Type with ...}’’.

In fact, the {\tt Type} is optional in this line; ‘‘{\tt with ...}’’ suffices.
Exports

To the right of the \spad{with} is a list of \spad{key{with}}
all the \spadgloss{exports}{export} of the category.
Each exported operation has a name and a type expressed by a
\spadgloss{declaration}{declaration} of the form
``\{\frenchspacing	t \{\it name\}: \{\it type\}\}''.

Categories can export symbols, as well as
\{\tt 0\} and \{\tt 1\} which denote
domain constants.\footnote{The
texts \{0\} and \{1\} are operation names in Axiom.} In the current implementation, all other exports are operations with
types expressed as \spadgloss{mappings}{mapping} with the syntax
\line{\centerline{\{\it source\quad\{->\quad\{\it target\}}}\line{\centerline{}}}
The category \spadtype{SetCategory} has a single export: the operation
\spadtype{=\}\ whose type is given by the mapping \{\tt \{\$, \$\} -> Boolean}. The \spadtype{\$} in a mapping type always means 'the domain.' Thus
the operation \spad{=}\ takes two arguments from the domain and
returns a value of type \spadtype{Boolean}.

The source part of the mapping here is given by a \{\tt tuple\}
consisting of two or more types separated by commas and enclosed in
categories.
If an operation takes only one argument, you can drop the parentheses around the source type.
If the mapping has no arguments, the source part of the mapping is either
left blank or written as \spad{()}. Here are examples of formats of various operations with some contrived names.

\begin{verbatim}
someIntegerConstant : \$
aZeroArgumentOperation: () -> Integer
aOneArgumentOperation: Integer -> \$
aTwoArgumentOperation: (Integer,\$) -> Void
\end{verbatim}
aThreeArgumentOperation: ($,Integer,$) -> Fraction($)

\end{verbatim}

\autobuttons
\end{page}

Documentation

\beginpage{ugCategoriesDocPage}{12.3. Documentation}
\beginscroll

The definition of \spadtype{SetCategory} above is missing an important component: its library documentation. Here is its definition, complete with documentation.

\beginImportant

1. Description:

2. \axiomType{SetCategory}\ is\ the\ basic\ category\ for\ describing\ a\ collection\ of\ elements\ with\ equality\ and\ a\ \axiomFun{coerce}\ to\ \axiomType{OutputForm}.

3. SetCategory():\ Category\ ==\ Join(Type,CoercibleTo\ OutputForm)\ with\ 

4. \axiomOp{=}\ \axiomOp{=}:\ (\$,\ $)\ ->\ Boolean\ tests\ if\ \axiom{\{x\}}\ and\ \axiom{\{y\}}\ are\ equal.

Documentary comments are an important part of constructor definitions. Documentation is given both for the category itself and for each export.

A description for the category precedes the code. Each line of the description begins in column one with \axiomSyntax{++}. The description starts with the word \tt{Description:}.

\endImportant

\footnote{Other
information such as the author’s name, date of creation, and so on, can go in this area as well but are currently ignored by Axiom.}

All lines of the description following the initial line are indented by the same amount.

{%\sloppy\}

Surround the name of any constructor (with or without parameters) with an \axiomType{}, similarly, surround an operator name with \axiomOp{}, an Axiom operation with \axiomFun{}, and a variable or Axiom expression with \axiom{}. Library documentation is given in a \TeX-like language so that it can be used both for hard-copy and for \Browse{}. These different wrappings cause operations and types to have mouse-active buttons in \Browse{}. For hard-copy output, wrapped expressions appear in a different font. The above documentation appears in hard-copy as:

\begin{quote}
\axiomType{SetCategory} is the basic category for describing a collection of elements with \axiomOp{=} (equality) and a \spadfun{coerce} to \axiomType{OutputForm}.
\end{quote}

\begin{quote}
\axiom{x = y} tests if \axiom{x} and \axiom{y} are equal.
\end{quote}

For our purposes in this chapter, we omit the documentation from further category descriptions.
Hierarchies

A second example of a category is \spadtype{SemiGroup}, defined by:

\begin{verbatim}
1. SemiGroup(): Category == SetCategory with
2.    "*": ($, $) -> $
3.    "**": ($, PositiveInteger) -> $
\end{verbatim}

This definition is as simple as that for \spadtype{SetCategory}, except that there are two exported operations. Multiple exported operations are written as a \spadgloss{pile}, that is, they all begin in the same column. Here you see that the category mentions another type, \spadtype{PositiveInteger}, in a signature. Any domain can be used in a signature.

Since categories extend one another, they form hierarchies. Each category other than \spadtype{Type} has one or more parents given by the one or more categories mentioned before the \spad{with} part of the definition.

\spadtype{SemiGroup} extends \spadtype{SetCategory} and \spadtype{SetCategory} extends both \spadtype{Type} and \spadtype{CoercibleTo (OutputForm)}. Since \spadtype{CoercibleTo (OutputForm)} also extends \spadtype{Type}, the mention of \spadtype{Type} in the definition is unnecessary but included for emphasis.
Membership

We say a category designates a class of domains. What class of domains? That is, how does Axiom know what domains belong to what categories? The simple answer to this basic question is key to the design of Axiom:

\beginImportant
\centerline{\bf Domains belong to categories by assertion.}
\endImportant

When a domain is defined, it is asserted to belong to one or more categories. Suppose, for example, that an author of domain \spadtype{String} wishes to use the binary operator \spadop{*} to denote concatenation. Thus \spad{"hello " * "there"} would produce the string \spad{"hello there"}. Actually, concatenation of strings in Axiom is done by juxtaposition or by using the operation \spadfunFrom{concat}{String}. The expression \spad{"hello " "there"} produces the string \spad{"hello there"}. The author of \spadtype{String} could then assert that \spadtype{String} is a member of \spadtype{SemiGroup}. According to our definition of \spadtype{SemiGroup}, strings would then also have the operation \spadop{**} defined automatically. Then \spad{"--" ** 4} would produce a string of eight dashes \spad{"--------"}. Since \spadtype{String} is a member of \spadtype{SemiGroup}, it also is a member of \spadtype{SetCategory} and thus has an operation \spadop{=} for testing that two strings are equal.

\texht{Now turn to the algebraic category hierarchy inside the front cover of this book.}

Any domain that is a member of a category extending \spadtype{SemiGroup} is a member of \spadtype{SemiGroup} (that is, it is a semigroup). In particular, any domain asserted to be a \spadtype{Ring} is a semigroup since \spadtype{Ring} extends \spadtype{Monoid}, that, in turn, extends \spadtype{SemiGroup}. The definition of \spadtype{Integer} in Axiom asserts that \spadtype{Integer} is a member of category \spadtype{IntegerNumberSystem}, that, in turn, asserts that it is
a member of \spad{EuclideanDomain}.

Now \spad{EuclideanDomain} extends \spad{PrincipalIdealDomain} and so on.

If you trace up the hierarchy, you see that \spad{EuclideanDomain} extends \spad{Ring}, and, therefore, \spad{SemiGroup}.

Thus \spad{Integer} is a semigroup and also exports the operations \spadop{*} and \spadop{**}.

\endscroll
\autobuttons
\end{page}

---

Defaults

\begin{page}{ugCategoriesDefaultsPage}{12.6. Defaults}
\beginscroll

We actually omitted the last part of the definition of \spad{SemiGroup} in Section 12.4\ignore{ugCategoriesHier}.

Here now is its complete Axiom definition.

\beginImportant

\begin{verbatim}
1. SemiGroup(): Category == SetCategory with
2.   *: ($, $) -> $
3.   **: ($, PositiveInteger) -> $
4. add
5.   import RepeatedSquaring($)
6.   x: $ ** n: PositiveInteger == expt(x, n)
\end{verbatim}

\endImportant

The \spad{add} part at the end is used to give ‘default definitions’ for \spadkey{add} exported operations. Once you have a multiplication
operation \spadop{*}, you can define exponentiation for positive integer exponents using repeated multiplication:
\centerline{\spad{x ** n = x * x * ... * x}
( \spad{n} copies of \spad{x} )}
This definition for \spadop{**} is called a \{it default\} definition. In general, a category can give default definitions for any operation it exports. Since \spadtype{SemiGroup} and all its category descendants in the hierarchy export \spadop{***}, any descendant category may redefine \spadop{**} as well.

A domain of category \spadtype{SemiGroup} (such as \spadtype{Integer}) may or may not choose to define its own \spad{**} operation. If it does not, a default definition that is closest (in a ‘‘tree-distance’’ sense of the hierarchy) to the domain is chosen.

The part of the category definition following an \spadop{add} operation is a \spadgloss{capsule}, as discussed in \texht{the previous chapter.}
{\downlink{``Packages''}{ugPackagesPage} in Chapter 11}\ignore{ugPackages}.}
The line
\begin{verbatim}
import RepeatedSquaring($)
\end{verbatim}
references the package \spadtype{RepeatedSquaring($)}, that is, the package \spadtype{RepeatedSquaring} that takes ‘‘this domain’’ as its parameter.
For example, if the semigroup \spadtype{Polynomial (Integer)} does not define its own exponentiation operation, the definition used may come from the package \spadtype{RepeatedSquaring (Polynomial (Integer))}. The next line gives the definition in terms of \spadfun{expt} from that package.

The default definitions are collected to form a ‘‘default package’’ for the category. The name of the package is the same as the category but with an ampersand (\spadSyntax{\&}) added at the end. A default package always takes an additional argument relative to the category.
Here is the definition of the default package \pspadtype{SemiGroup\&} as automatically generated by Axiom from the above definition of \spadtype{SemiGroup}.

\beginImportant

\noindent{\tt 1.
\tt \ SemiGroup\&($):\ Exports\ ==\ Implementation\ where}
\tt
\noindent{\tt 2.
\tt \ 	\ $:\ SemiGroup$
\tt
\noindent{\tt 3.
\tt \ 	\ Exports\ ==\ with$)newline
\tt
\noindent{\tt 4.
\tt \ 	\ (\spad{n} copies of \spad{x} )}}

}
Axioms

\begin{page}{ugCategoriesAxiomsPage}{12.7. Axioms}
\beginscroll
In \texht{the previous section} (ugCategoriesDefaultsPage) you saw the complete Axiom program defining \index{axiom} \spadtype{SemiGroup}. According to this definition, semigroups (that is, are sets with the operations \spadop{*} and \spadop{**}.

You might ask: ‘‘Aside from the notion of default packages, isn’t a category just a \spadgloss{macro}, that is, a shorthand equivalent to the two operations \spadop{*} and \spadop{**} with their types?’’ If a category were a macro, every time you saw the word \spadtype{SemiGroup}, you would rewrite it by its list of exported operations. Furthermore, every time you saw the exported operations of \spadtype{SemiGroup} among the exports of a constructor, you could conclude that the constructor exported \spadtype{SemiGroup}.

A category is \{it not\} a macro and here is why.

The definition for \spadtype{SemiGroup} has documentation that states:

\begin{quotation}
Category \spadtype{SemiGroup} denotes the class of all multiplicative semigroups, that is, a set with an associative operation \spadop{*}.
\end{quotation}
According to the author's remarks, the mere exporting of an operation named \spad{\ast} and \spad{\ast\ast} is not enough to qualify the domain as a \spad{SemiGroup}. In fact, a domain can be a semigroup only if it explicitly exports a \spad{\ast\ast} and a \spad{\ast} satisfying the associativity axiom.

In general, a category name implies a set of axioms, even mathematical theorems. There are numerous axioms from \spad{Ring}, for example, that are well-understood from the literature. No attempt is made to list them all. Nonetheless, all such mathematical facts are implicit by the use of the name \spad{Ring}.

\begin{scroll}
\autobuttons
\end{page}

---

Correctness

\begin{page}{ugCategoriesCorrectnessPage}{12.8. Correctness}

While such statements are only comments, Axiom can enforce their intention simply by shifting the burden of responsibility onto the author of a domain. A domain belongs to category \spad{Ring} only if the author asserts that the domain belongs to \spad{Ring} or to a category that extends \spad{Ring}.

This principle of assertion is important for large user-extendable systems. Axiom has a large library of operations offering facilities in many areas. Names such as \spad{norm} and \spad{product}, for example, have diverse meanings in diverse contexts. An inescapable hindrance to users would be to force those who wish to extend Axiom to always invent new names for operations.

%>> I don't think disambiguate is really a word, though I like it
Axiom allows you to reuse names, and then use context to disambiguate one from another.

Here is another example of why this is important. Some languages, such as \textbf{APL}, denote the \spadtype{Boolean} constants \spad{true} and \spad{false} by the integers \spad{1} and \spad{0}. You may want to let infix operators \spadop{+} and \spadop{*} serve as the logical operators \spadfun{or} and \spadfun{and}, respectively. But note this: \spadtype{Boolean} is not a ring. The \spad{inverse axiom} for \spadtype{Ring} states:

\begin{center}
\spad{x\text{ has an additive inverse } y\text{ such that } x + y = 0.}
\end{center}

Every element \spad{x} has no inverse---there is no inverse element \spad{a} such that \spad{1 + a = 0} (in terms of booleans, \spad{(true \text{ or } a) = false}). Nonetheless, Axiom \spad{could} easily and correctly implement \spadtype{Boolean} this way. \spadtype{Boolean} simply would not assert that it is of category \spadtype{Ring}. Thus the \spadop{+} for \spadtype{Boolean} values is not confused with the one for \spadtype{Ring}. Since the \spadtype{Polynomial} constructor requires its argument to be a ring, Axiom would then refuse to build the domain \spadtype{Polynomial[Boolean]}. Also, Axiom would refuse to wrongfully apply algorithms to \spadtype{Boolean} elements that presume that the ring axioms for \spadop{+} hold.

\section*{Attributes}

\begin{itemize}
\item “Categories” (ugCategoriesPage) 15 on page 2403
\item “Category Assertions” (ugDomainsAssertionsPage) 16 on page 2429
\end{itemize}

Most axioms are not computationally useful.
Those that are can be explicitly expressed by what Axiom calls an \spadgloss{attribute}.
The attribute \spadatt{commutative("*")}, for example, is used to assert
that a domain has commutative multiplication.
Its definition is given by its documentation:

\begin{verbatim}
A domain \spad{R} has \spadatt{commutative("*")}
if it has an operation ":\spad{R}\to\spad{R}\}
such that \spad{x * y = y * x}.
\end{verbatim}

Just as you can test whether a domain has the category \spadtype{Ring}, you
can test that a domain has a given attribute.

\xtc{
Do polynomials over the integers
have commutative multiplication?
}
\spadpaste{Polynomial Integer has commutative("*")}

\xtc{
Do matrices over the integers
have commutative multiplication?
}
\spadpaste{Matrix Integer has commutative("*")}

Attributes are used to conditionally export and define
operations for a domain (see
\downlink{``Category Assertions''}{ugDomainsAssertionsPage} in
Section 13.3\ignore{ugDomainsAssertions}). Attributes can also be asserted in a category definition.

After mentioning category \spadtype{Ring} many times in this book,
it is high time that we show you its definition:

\beginImportant
\begin{verbatim}
1. \ Ring():\ Category ==}
2. \ 
3. \ 
4. \ 
5. \ 
6. \ 
7. \ 
8. \ 
\end{verbatim}
\endImportant
There are only two new things here. First, look at the \spadSyntax{\$\$} on the last line. This is not a typographic error! The first \spadSyntax{\$} says that the \spad{1} is to come from some domain. The second \spadSyntax{\$} says that the domain is ‘‘this domain.’’ If \spadSyntax{\$} is \spadtype{Fraction(Integer)}, this line reads \tt{coerce(n) == n * 1\$Fraction(Integer)}.

The second new thing is the presence of attribute ‘‘\spad(unitsKnown)’’. Axiom can always distinguish an attribute from an operation. An operation has a name and a type. An attribute has no type. The attribute \spadatt{unitsKnown} asserts a rather subtle mathematical fact that is normally taken for granted when working with rings. With this axiom, the units of a domain are the set of elements \spad{x} that each have a multiplicative inverse \spad{y} in the domain. Thus \spad{1} and \spad{-1} are units in domain \spadtype{Integer}. Also, for \spadtype{Fraction Integer}, the domain of rational numbers, all non-zero elements are units.) Because programs can test for this attribute, Axiom can correctly handle rather more complicated mathematical structures (ones that are similar to rings but do not have this attribute).

\begin{verbatim}
(1) true
Type: Boolean
\end{verbatim}

\begin{verbatim}
(2) false
Type: Boolean
\end{verbatim}
Like domain constructors, category constructors can also have parameters. For example, category \spadtype{MatrixCategory} is a parameterized category for defining matrices over a ring \spad{R} so that the matrix domains can have different representations and indexing schemes. Its definition has the form:

\begin{verbatim}
1. MatrixCategory(R,Row,Col): Category ==
2. " TwoDimensionalArrayCategory(R,Row,Col) with ..."
\end{verbatim}

The category extends \spadtype{TwoDimensionalArrayCategory} with the same arguments. You cannot find \spadtype{TwoDimensionalArrayCategory} in the algebraic hierarchy listing. Rather, it is a member of the data structure hierarchy, given inside the back cover of this book. In particular, \spadtype{TwoDimensionalArrayCategory} is an extension of \spadtype{HomogeneousAggregate} since its elements are all one type.

The domain \spadtype{Matrix(R)}, the class of matrices with coefficients from domain \spad{R}, asserts that it is a member of category \spadtype{MatrixCategory(R, Vector(R), Vector(R))}. The parameters of a category must also have types. The first parameter to \spadtype{MatrixCategory} \spad{R} is required to be a ring. The second and third are required to be domains of category \spadtype{FiniteLinearAggregate(R)}.

This is another extension of
\spadtype{HomogeneousAggregate} that you can see in the data structure hierarchy.\}
In practice, examples of categories having parameters other than domains are rare.

Adding the declarations for parameters to the definition for \spadtype{MatrixCategory}, we have:

\beginImportant
\noindent
\tt 1. \ \ R: \ Ring
\tt 2. \ \ (Row, Col): \ FiniteLinearAggregate(R)
\tt 3. \ \n
\tt 4. \ \ MatrixCategory(R, Row, Col): \ Category ==
\tt 5. \ \ TwoDimensionalArrayCategory(R, Row, Col) \ with \ ...
\endImportant

\endscroll
\autobuttons
\end{page}

---

**Conditionals**

⇐ “Categories” (ugCategoriesPage) 15 on page 2403
⇒ “Conditionals” (ugPackagesCondsPage) 14 on page 2390

---

As categories have parameters, the actual operations exported by a category can depend on these parameters. As an example, the operation \spadfunFrom{determinant}{MatrixCategory} from category \spadtype{MatrixCategory} is only exported when the underlying domain \spad{R} has commutative multiplication:

\beginverbatim
if R has commutative("*") then
determinant: $ -> R
\endverbatim

Conditionals can also define conditional extensions of a category.
Here is a portion of the definition of \spadtype{QuotientFieldCategory}:

\beginImportant

\noindent
\tt
1. \ QuotientFieldCategory(R) \ : \ Category \ == \ ... \ with \ ...
2. \ if \ R \ has \ OrderedSet \ then \ OrderedSet
3. \ if \ R \ has \ IntegerNumberSystem \ then
4. \ ceiling: \ $\rightarrow R$
5. \ ...
\endImportant

Think of category \spadtype{QuotientFieldCategory(R)} as denoting the domain \spadtype{Fraction(R)}, the class of all fractions of the form \(a/b\) for elements of \spad{R}. The first conditional means in English: ‘‘If the elements of \spad{R} are totally ordered (\spad{R} is an \spadtype{OrderedSet}), then so are the fractions \(a/b)’’.

The second conditional is used to conditionally export an operation \spadfun{ceiling} which returns the smallest integer greater than or equal to its argument. Clearly, ‘‘ceiling’’ makes sense for integers but not for polynomials and other algebraic structures. Because of this conditional, the domain \spadtype{Fraction(Integer)} exports an operation \spadfun{ceiling}: \spadsig{Fraction Integer}{Integer}, but \spadtype{Fraction Polynomial Integer} does not.

Conditionals can also appear in the default definitions for the operations of a category. For example, a default definition for \spadfunFrom{ceiling}{Field} within the part following the \spadop{add} reads:

\beginverbatim
if R has IntegerNumberSystem then
  ceiling x == ...
\endverbatim

Here the predicate used is identical to the predicate in the \tt \spad{Exports} part. This need not be the case. See \downlink{``Conditionals’’}{ugPackagesCondsPage} in Section 11.8 for a more complicated example.

\endscroll
\autobuttons
\end{page}
Anonymous Categories

The part of a category to the right of a `with` is also regarded as a category---an "anonymous category." Thus you have already seen a category definition. The `Exports` part of the package \spadtype{DrawComplex} (\downlink{"Abstract Datatypes"}{ugPackagesAbstractPage} in Section 11.3\ignore{ugPackagesAbstract}) is an anonymous category. This is not necessary. We could, instead, give this category a name:

\beginImportant
\begin{verbatim}
  1. \hspace{1em} DrawComplexCategory():\ Category\ ==\ with
  2. \hspace{2em} drawComplex:\ (C ->\ C,S,S,Boolean) ->\ VIEW3D
  3. \hspace{2em} drawComplexVectorField:\ (C ->\ C,S,S) ->\ VIEW3D
  4. \hspace{2em} setRealSteps:\ INT\ ->\ INT
  5. \hspace{2em} setImagSteps:\ INT\ ->\ INT
  6. \hspace{2em} setClipValue:\ DFLOAT->\ DFLOAT
\end{verbatim}
\endImportant

and then define \spadtype{DrawComplex} by:

\beginImportant
\begin{verbatim}
  1. \hspace{1em} DrawComplex():\ DrawComplexCategory\ ==\ Implementation
\end{verbatim}
\endImportant

There is no reason, however, to give this list of exports a name since no other domain or package exports it.
In fact, it is rare for a package to export a named category. As you will see in the next chapter, however, it is very common for the definition of domains to mention one or more category before the \{\tt with\}.
\spadkey{with}
\endscroll
\autobuttons
\end{page}
Chapter 16

Users Guide Chapter 13 (ug13.ht)

Domains

We finally come to the \spadgloss{domain constructor}. A few subtle differences between packages and domains turn up some interesting issues. We first discuss these differences then describe the resulting issues by illustrating a program for the \axiomType{QuadraticForm} constructor. After a short example of an algebraic constructor, \axiomType{CliffordAlgebra}, we show how you use domain constructors to build a database query facility.
Packages are special cases of domains. What is the difference between a package and a domain that is not a package? By definition, there is only one difference: a domain that is not a package has the symbol \texttt{\$} appearing somewhere among the types of its exported operations. The \texttt{\$} denotes "this domain." If the \texttt{\$} appears before the \texttt{\$\rightarrow} in the type of a signature, it means the operation takes an element from the domain as an argument. If it appears after the \texttt{\$\rightarrow}, then the operation returns an element of the domain.

If no exported operations mention \texttt{\$}, then evidently there is nothing of interest to do with the objects of the domain. You might then say that a package is a "boring" domain! But, as you saw in Chapter 11\texttt{\ignore{ugPackages}} in Chapter 11, packages are a very useful notion indeed. The exported operations of a package depend solely on
the parameters to the package constructor and other explicit domains.

To summarize, domain constructors are versatile structures that serve two distinct practical purposes: Those like \axiomType{Polynomial} and \axiomType{List} describe classes of computational objects; others, like \pspadtype{SortPackage}, describe packages of useful operations. As in the last chapter, we focus here on the first kind.

Definitions

— ug13.ht —

\begin{page}{ugDomainsDefsPage}{13.2. Definitions}
\beginscroll

The syntax for defining a domain constructor is the same as for any function in Axiom:
\centerline{\tt \it DomainForm} : \it Exports == \it Implementation}

As this definition usually extends over many lines, a \axiom{where} expression is generally used instead.
\spadkey{where}

\beginImportant
A recommended format for the definition of a domain is:
\begin{verbatim}
{\it DomainForm} : {\it Exports} ==
\hspace{8pc} {\it Implementation} where
\hspace{1pc} {\it optional type declarations} \\
\hspace{3pc} {\it list of exported operations} \\
\hspace{8pc} {\it list of function definitions for exported operations}
\end{verbatim}
\endImportant

\end{scroll}
\end{page}
A complete domain constructor definition for \rm{QuadraticForm} is shown in Figure \ref{fig-quadform}. Interestingly, this little domain illustrates all the new concepts you need to learn.

\beginImportant
\noindent

27. \quad\texttt{m}\newline
28. \quad\texttt{m}\newline
\texttt{QuadraticForm}\ requires\ a\ symmetric\ matrix\newline
\endImportant
A domain constructor can take any number and type of parameters. \axiomType{QuadraticForm} takes a positive integer \axiom{n} and a field \axiom{K} as arguments. Like a package, a domain has a set of explicit exports and an implementation described by a capsule. Domain constructors are documented in the same way as package constructors.

Domain \axiomType{QuadraticForm(n, K)}, for a given positive integer \axiom{n} and domain \axiom{K}, explicitly exports three operations:

\begin{itemize}
\item \axiom{quadraticForm(A)} creates a quadratic form from a matrix \axiom{A}.
\item \axiom{matrix(q)} returns the matrix \axiom{A} used to create the quadratic form \axiom{q}.
\item \axiom{q.v} computes the scalar $v^T A v$ for a given vector \axiom{v}.
\end{itemize}

Compared with the corresponding syntax given for the definition of a package, you see that a domain constructor has three optional parts to its definition: \{it Category Assertions\}, \{it Add Domain\}, and \{it Representation\}.

---

\section*{Category Assertions}

\begin{itemize}
\item “notitle” (ugCategoriesCorrectnessPage) 15 on page 2415
\item “notitle” (ugCategoriesConditionalsPage) 15 on page 2420
\end{itemize}
The \{\it Category Assertions\} part of your domain constructor
definition lists those categories of which all domains created by the
constructor are unconditionally members. The word \textquote{\textquote{unconditionally}}
means that membership in a category does not depend on the values of
the parameters to the domain constructor. This part thus defines the
link between the domains and the category hierarchies given on the
inside covers of this book. As described in
\downlink{\textquote{\textquote{Correctness'}}}{ugCategoriesCorrectnessPage}
in Section 12.8\ignore{ugCategoriesCorrectness}, it is
this link that makes it possible for you to pass objects of the
domains as arguments to other operations in Axiom.

Every \axiomType{QuadraticForm} domain is declared to be
unconditionally a member of category \axiomType{AbelianGroup}. An
abelian group is a collection of elements closed under addition.
Every object \{\it x\} of an abelian group has an additive inverse \{\it y\}
such that \textquote{$x + y = 0$}\{\axiom{{\it x} + {\it y} = 0}\}. The
exports of an abelian group include \axiom{0}, \axiomOp{+},
\axiomOp{-}, and scalar multiplication by an integer. After asserting
that \axiomType{QuadraticForm} domains are abelian groups, it is
possible to pass quadratic forms to algorithms that only assume
arguments to have these abelian group properties.

In
\downlink{\textquote{\textquote{Conditionals'}}}{ugCategoriesConditionalsPage}
in Section 12.11\ignore{ugCategoriesConditionals}, you
saw that \axiomType{Fraction(R)}, a member of
\axiomType{QuotientFieldCategory(R)}, is a member of
\axiomType{OrderedSet} if \axiom{R} is a member of
\axiomType{OrderedSet}. Likewise, from the \{\it \tt Exports\} part of the
definition of \axiomType{ModMonic(R, S)}, \begin{verbatim}
UnivariatePolynomialCategory(R) with
   if R has Finite then Finite
...
\end{verbatim}
you see that \axiomType{ModMonic(R, S)} is a member of
\axiomType{Finite} is \axiom{R} is.

The \{\tt Exports\} part of a domain definition is the same kind of
expression that can appear to the right of an \axiomSyntax{==} in a
category definition. If a domain constructor is unconditionally a
member of two or more categories, a \axiom{Join} form is used.
\spadkey{Join} The \{\tt Exports\} part of the definition of
\axiomType{FlexibleArray(S)} reads, for example:
\begin{verbatim}
Join(ExtensibleLinearAggregate(S),
   OneDimensionalArrayAggregate(S)) with...\end{verbatim}
Before looking at the \textit{Implementation} part of \texttt{QuadraticForm}, let's try some examples.

\texttt{Build a domain \texttt{QF}.}

Browse

— ug13.ht —

\begin{page}{ugDomainsBrowsePage}{13.5. Browse}
\beginscroll

The \Browse{} facility of Hyperdoc is useful for investigating the properties of domains, packages, and categories. From the main Hyperdoc menu, move your mouse to \bf Browse and click on the left mouse button. This brings up the \Browse{} first page. Now, with your mouse pointer somewhere in this window, enter the string 'quadraticform' into the input area (all lower case letters will do). Move your mouse to \bf Constructors and click. Up comes a page describing \axiomType{QuadraticForm}.

From here, click on \bf Description. This gives you a page that includes a part labeled by 'Description:'. You also see the types for arguments \axiom{n} and \axiom{K} displayed as well as the fact that \axiomType{QuadraticForm} returns an \axiomType{AbelianGroup}. You can go and experiment a bit by selecting \bf Field with your mouse. Eventually, use \UpButton{} several times to return to the first page on \axiomType{QuadraticForm}.

Select \bf Operations to get a list of operations for \axiomType{QuadraticForm}. You can select an operation by clicking on it to get an individual page with information about that operation. Or you can select the buttons along the bottom to see alternative views or get additional information on the operations. Then return to the page on \axiomType{QuadraticForm}.

Select \bf Cross Reference to get another menu. This menu has buttons for \bf Parents, \bf Ancestors, and others. Clicking on \bf Parents, you see that \axiomType{QuadraticForm} has one parent \axiomType{AbelianMonoid}.

CHAPTER 16. USERS GUIDE
CHAPTER 13 (UG13.HT)

Representation

⇒ “notitle” (ugDomainsDemoPage) 16 on page 2431

The \tt Implementation part of an Axiom capsule for a
domain constructor uses the special variable \axiom{Rep} to
identify the lower level data type used to represent the objects
of the domain.
The \axiom{Rep} for quadratic forms is \axiomType{SquareMatrix(n, K)}.
This means that all objects of the domain are required to be
\axiom{n} by \axiom{n} matrices with elements from \axiomType{K}.

The code for \axiomFun{quadraticForm} in Figure \ref{fig-quadform} on
page \pageref{fig-quadform} checks that the matrix is symmetric and
then converts it to \axiomSyntax{$}, which means, as usual, ‘‘this
domain.’’ Such explicit conversions \index{conversion} are generally
required by the compiler. Aside from checking that the matrix is
symmetric, the code for this function essentially does nothing. The
\frenchs{tt m :: $} on line 28 coerces \axiom{m} to a
quadratic form. In fact, the quadratic form you created in step (3)
of \downlink{‘‘A Demo’’}{ugDomainsDemoPage} in Section
13.4\ignore{ugDomainsDemo} is just the matrix you
passed it in disguise! Without seeing this definition, you would not
know that. Nor can you take advantage of this fact now that you do
know! When we try in the next step of
\downlink{‘‘A Demo’’}{ugDomainsDemoPage} in Section
13.4\ignore{ugDomainsDemo} to regard \axiom{q} as a
matrix by asking for \axiomFun{nrows}, the number of its rows, Axiom
gives you an error message saying, in effect, ‘‘Good try, but this
won’t work!’’

The definition for the \spadfunFrom{matrix}{QuadraticForm}
function could hardly be simpler:
it just returns its argument after explicitly
\spadglossSee{coercing}{coerce} its argument to a matrix.
Since the argument is already a matrix, this coercion does no
computation.

Within the context of a capsule, an object of \axiomSyntax{$} is
regarded both as a quadratic form \tt and as a
Multiple Representations

To write functions that implement the operations of a domain, you want to choose the most computationally efficient data structure to represent the elements of your domain.

A classic problem in computer algebra is the optimal choice for an internal representation of polynomials. If you create a polynomial, say $3x^2 + 5$, how does Axiom hold this value internally? There are many ways. Axiom has nearly a dozen different representations of polynomials, one to suit almost any purpose. Algorithms for solving polynomial equations work most efficiently with polynomials represented one way, whereas those for factoring polynomials are most efficient using another. One often-used representation is a list of terms, each term consisting of exponent-coefficient records written in the order of decreasing exponents. For example, the polynomial $3x^2 + 5$ is represented by the list $[[e:2, c:3], [e:0, c:5]]$. What is the optimal data structure for a matrix?
It depends on the application. For large sparse matrices, a linked-list structure of records holding only the non-zero elements may be optimal. If the elements can be defined by a simple formula \( f(i,j) \), then a compiled function for \( f \) may be optimal. Some programmers prefer to represent ordinary matrices as vectors. Others prefer to represent matrices by one big linear array where elements are accessed with linearly computable indexes.

While all these simultaneous structures tend to be confusing, Axiom provides a helpful organizational tool for such a purpose: categories. \axiomType{PolynomialCategory}, for example, provides a uniform user interface across all polynomial types. Each kind of polynomial implements functions for all these operations, each in its own way.

If you use only the top-level operations in \axiomType{PolynomialCategory} you usually do not care what kind of polynomial implementation is used.

---

Add Domain

\begin{page}{ugDomainsAddDomainPage}{13.8. Add Domain}

\begin{verbatim}
%>> I've often thought, though, that it would be nice to be
%>> be able to use conditionals for representations.

Within a given domain, however, you define (at most) one representation.\footnote{You can make that representation a \pspadtype{Union} type, however. See \downlink{``Unions''}{ugTypesUnionsPage} in Section 2.5\ignore{ugTypesUnions} for examples of unions.}
If you want to have multiple representations (that is, several domains, each with its own representation), use a category to describe the (\tt exports), then define separate domains for each representation.

\end{verbatim}

\end{page}
The capsule part of \tt Implementation\ defines functions that implement the operations exported by the domain—usually only some of the operations. In our demo in \downlink{``A Demo''}{ugDomainsDemoPage} in Section 13.4\ignore{ugDomainsDemo}, we asked for the value of \axiom{3*q-q+q}. Where do the operations \axiomOp{*}, \axiomOp{+}, and \axiomOp{-} come from? There is no definition for them in the capsule!

The \tt Implementation\ part of a definition can optionally specify an ‘\texttt{add-domain}’ to the left of an \tt spadkey{add} (for \axiomType{QuadraticForm}, defines \axiomType{SquareMatrix(n,K)} is the add-domain). The meaning of an add-domain is simply this: if the capsule part of the \tt Implementation\ does not supply a function for an operation, Axiom goes to the add-domain to find the function. So do \axiomOpFrom{*}{QuadraticForm}, \axiomOpFrom{+}{QuadraticForm} and \axiomOpFrom{-}{QuadraticForm} come from \axiomType{SquareMatrix(n,K)}?

\endscroll
\autobuttons
\end{page}

\section*{Defaults}

\begin{quote}
\textbf{⇒ “notitle”} \ (ugPackagesPage) \ 14 \ on page \ 2375
\textbf{⇒ “notitle”} \ (ugCategoriesDefaultsPage) \ 15 \ on page \ 2412
\end{quote}

In \downlink{``Packages''}{ugPackagesPage} in Chapter 11\ignore{ugPackages}, we saw that categories can provide default implementations for their operations. How and when are they used?

When Axiom finds that \axiomType{QuadraticForm(2, Fraction Integer)} does not implement the operations \axiomOp{*}, \axiomOp{+}, and \axiomOp{-}, it goes to \axiomType{SquareMatrix(2,Fraction Integer)} to find it.
As it turns out, \texttt{SquareMatrix(2, Fraction Integer)} does not implement \texttt{it any} of these operations!

What does Axiom do then? Here is its overall strategy. First, Axiom looks for a function in the capsule for the domain. If it is not there, Axiom looks in the add-domain for the operation. If that fails, Axiom searches the add-domain of the add-domain, and so on. If all those fail, it then searches the default packages for the categories of which the domain is a member. In the case of \texttt{QuadraticForm}, it searches \texttt{AbelianGroup}, then its parents, grandparents, and so on. If this fails, it then searches the default packages of the add-domain. Whenever a function is found, the search stops immediately and the function is returned. When all fails, the system calls \texttt{error} to report this unfortunate news to you. To find out the actual order of constructors searched for \texttt{QuadraticForm}, consult \texttt{Browse}: from the \texttt{QuadraticForm}, click on \texttt{Cross Reference}, then on \texttt{Lineage}.

Let’s apply this search strategy for our example \texttt{3*q-q+q}. The scalar multiplication comes first. Axiom finds a default implementation in \texttt{AbelianGroup}. Remember from \texttt{Defaults} in Section 12.6 that \texttt{SemiGroup} provides a default definition for \texttt{x^n} by repeated squaring? \texttt{AbelianGroup} similarly provides a definition for \texttt{n*x} by repeated doubling.

But the search of the defaults for \texttt{QuadraticForm} fails to find any \texttt{+} or \texttt{*} in the default packages for the ancestors of \texttt{QuadraticForm}. So it now searches among those for \texttt{SquareMatrix}. Category \texttt{MatrixCategory}, which provides a uniform interface for all matrix domains, is a grandparent of \texttt{SquareMatrix} and has a capsule defining many functions for matrices, including matrix addition, subtraction, and scalar multiplication. The default package \texttt{MatrixCategory\&} is where the functions for \texttt{QuadraticForm} and \texttt{spadfunFrom(-)}\texttt{QuadraticForm} come from.

You can use \texttt{Browse} to discover where the operations for \texttt{QuadraticForm} are implemented. First, get the page describing \texttt{QuadraticForm}. With your mouse somewhere in this window, type a ‘‘2’’, press the \texttt{fbox{bf Tab}} key, and then enter ‘‘Fraction Integer’’ to indicate that you want the domain \texttt{QuadraticForm(2, Fraction Integer)}. Now click on \texttt{Operations} to get a table of operations and on \texttt{OpFrom(+)QuadraticForm} to get a page describing the \texttt{OpFrom(+)} operation. Finally, click on \texttt{implementation} at the bottom.
Aside from the notion of where an operation is implemented, a useful notion is the "it origin" or 'home' of an operation. When an operation (such as \spadfunFrom{quadraticForm}{QuadraticForm}) is explicitly exported by a domain (such as \axiomType{QuadraticForm}), you can say that the origin of that operation is that domain. If an operation is not explicitly exported from a domain, it is inherited from, and has as origin, the (closest) category that explicitly exports it. The operations \axiomOpFrom{+}{AbelianMonoid} and \axiomOpFrom{-}{AbelianMonoid} of \axiomType{QuadraticForm}, for example, are inherited from \axiomType{AbelianMonoid}. As it turns out, \axiomType{AbelianMonoid} is the origin of virtually every \axiomOp{+} operation in Axiom!

Again, you can use \Browse{} to discover the origins of operations. From the \Browse{} page on \axiomType{QuadraticForm}, click on \bf{Operations}, then on \bf{bf origins} at the bottom of the page.

The origin of the operation is the \it only place where on-line documentation is given. However, you can re-export an operation to give it special documentation. Suppose you have just invented the world's fastest algorithm for inverting matrices using a particular internal representation for matrices. If your matrix domain just declares that it exports \axiomType{MatrixCategory}, it exports the \axiomFun{inverse} operation, but the documentation the user gets from \Browse{} is the standard one from \axiomType{MatrixCategory}. To give your version of \axiomFun{inverse} the attention it deserves, simply export the operation explicitly with new documentation. This redundancy gives \axiomFun{inverse} a new origin and tells \Browse{} to present your new documentation.
In Axiom, a domain could be defined using only an add-domain and no capsule. Although we talk about rational numbers as quotients of integers, there is no type \texttt{RationalNumber} in Axiom. To create such a type, you could compile the following ‘short-form’ definition:

\beginImportant
\noindent
\texttt{1. \ RationalNumber() \ == \ Fraction(Integer)}
\endImportant

The \texttt{Exports} part of this definition is missing and is taken to be equivalent to that of \texttt{Fraction(Integer)}. Because of the add-domain philosophy, you get precisely what you want. The effect is to create a little stub of a domain. When a user asks to add two rational numbers, Axiom would ask \texttt{RationalNumber} for a function implementing this \texttt{+}. Since the domain has no capsule, the domain then immediately sends its request to \texttt{Fraction (Integer)}. The short form definition for domains is used to define such domains as \texttt{MultivariatePolynomial}:

\beginImportant
\noindent
\texttt{1. \ MultivariatePolynomial(vl:\ List Symbol, R:\ Ring) \ ==}
\texttt{2. \ \ \ \ \ SparseMultivariatePolynomial(R, vl)}
\texttt{3. \ \ \ \ \ \ \ OrderedVariableList vl)}
\endImportant

The \texttt{Exports} part of this definition is missing and is taken to be equivalent to that of \texttt{MultivariatePolynomial}. Because of the add-domain philosophy, you get precisely what you want. The effect is to create a little stub of a domain. When a user asks to add two rational numbers, Axiom would ask \texttt{RationalNumber} for a function implementing this \texttt{+}. Since the domain has no capsule, the domain then immediately sends its request to \texttt{Fraction (Integer)}.
Example 1: Clifford Algebra

⇒ “notitle” (CliffordAlgebraXmpPage) 3.15 on page 234
— ug13.ht —

% Now that we have \axiomType{QuadraticForm} available, let's put it to use. Given some quadratic form \smath{Q} described by an \smath{n} by \smath{n} matrix over a field \smath{K}, the domain \axiomType{CliffordAlgebra}(n, K, Q) defines a vector space of dimension \texht{$2^n$}{2**n} over \smath{K}. This is an interesting domain since complex numbers, quaternions, exterior algebras and spin algebras are all examples of Clifford algebras.

The basic idea is this: the quadratic form \axiom{Q} defines a basis \texht{$e_1,e_2\ldots,e_n$}{e1,e2,...,en} for the vector space \texht{$K^n$}{K**n}---the direct product of \axiom{K} with itself \axiom{n} times. From this, the Clifford algebra generates a basis of \texht{$2^n$}{2**n} elements given by all the possible products of the \texht{$e_i$}{axiom{ei}} in order without duplicates, that is, \texht{1, e_1, e_2, e_1*e_2, e_3, e_1*e_3, e_2*e_3, e_1*e_2*e_3}, and so on.

The algebra is defined by the relations
\begin{verbatim}
 ei*ei = Q(ei)
 ei*ej = -ej*ei,  i ≠ j
\end{verbatim}
Now look at the snapshot of its definition given in Figure \ref{fig-clifalg}.

Lines 9-10 show part of the definitions of the \tt{Exports}.

A Clifford algebra over a field \axiom{K} is asserted to be a ring,
an algebra over \axiom{K}, and a vector space over \axiom{K}.

Its explicit exports include
\axiom{e(n),} which returns the \eth{\axiom{n}} unit element.

\beginImportant
\noindent
\beginverbatim
{\tt 1. \ NonNegativeInteger} \newline
{\tt 2. \ PositiveInteger} \newline

{\tt 25. \ x \ * \ y \ := \} \newline
{\tt 26. \ z \ := \ New} \newline
{\tt 27. } \newline
{\tt 28. } \newline
if x.ix \ notequal\{\y \ 0 then \ for iy in 0..dim-1 \ repeat}\newline
{\tt 29. } \newline
{\tt 30. } \newline
then \ addMonomProd(x.ix,iy,\ y.iy,\ iy,z)\newline
{\tt 31. } \newline
\end{verbatim}
\endImportant
The \tt Implementation part begins by defining a local variable \axiom{Qeelist} to hold the list of all \axiom{q.v} where \axiom{v} runs over the unit vectors from 1 to the dimension \axiom{n}. Another local variable \axiom{dim} is set to \texht{$2^n$}{2**n}, computed once and for all.

The representation for the domain is \axiomType{PrimitiveArray(K)}, which is a basic array of elements from domain \axiom{K}.

Line 18 defines \axiom{New} as shorthand for the more lengthy expression \axiom{new(dim, 0\$K\$Rep)}, which computes a primitive array of length \texht{$2^n$}{2**n} filled with \axiom{0}'s from domain \axiom{K}.

Lines 19-22 define the sum of two elements \axiom{x} and \axiom{y} straightforwardly.

Example 2: Building A Query Facility

\begin{itemize}
\item \textbf{Example 2: Building A Query Facility}
\end{itemize}
We now turn to an entirely different kind of application, building a query language for a database.

Here is the practical problem to solve. The \Browse{} facility of Axiom has a database for all operations and constructors which is stored on disk and accessed by Hyperdoc. For our purposes here, we regard each line of this file as having eight fields: \tt{class, name, type, nargs, exposed, kind, origin,} and \tt{condition.} Here is an example entry:

\beginverbatim
o`determinant`$->R`1`x`d`Matrix(R)`has(R,commutative("*"))
\end{verbatim}

In English, the entry means:

\begin{quote}
\texttt{The operation \axiomFun{determinant}: \spadsig{$}{R} with \textit{1} argument, is \textit{exposed} and is exported by \textit{domain} \axiomType{Matrix(R)} if \texttt{R has commutative("*")}.}
\end{quote}

Our task is to create a little query language that allows us to get useful information from this database.
First we design a simple language for accessing information from the database.

We have the following simple model in mind for its design.

Think of the database as a box of index cards.

There is only one search operation---it takes the name of a field and a predicate (a boolean-valued function) defined on the fields of the index cards.

When applied, the search operation goes through the entire box selecting only those index cards for which the predicate is true.

The result of a search is a new box of index cards. This process can be repeated again and again.

The predicates all have a particularly simple form: \( \text{symbol} \) \( \text{=} \) \( \text{pattern} \), where \( \text{symbol} \) designates one of the fields, and \( \text{pattern} \) is a "search string"---a string that may contain a "(\( \text{?} \) *)" as a wildcard.

Wildcards match any substring, including the empty string.

Thus the pattern \( \text{"?ma*t"} \) matches \( \text{"mat"}, \text{"doormat"} \) and \( \text{"smart"}. \)

To illustrate how queries are given, we give you a sneak preview of the facility we are about to create.

\texttt{Extract the database of all Axiom operations.}

\texttt{\spadpaste{ops := getDatabase("o")\bound{o1}}} 

\texttt{How many exposed three-argument \texttt{axiomFun(map)} operations involving streams?}

\texttt{\spadpaste{ops.(name="map").(nargs="3").(type="*Stream*") \bound{o2}\free{o1}}
As usual, the arguments of \axiomFun{elt} \axiomSyntax{.} associate to the left.
The first \axiomFun{elt} produces the set of all operations with name \ttt{map}.
The second \axiomFun{elt} produces the set of all map operations with three arguments.
The third \axiomFun{elt} produces the set of all three-argument map operations having a type mentioning \axiomType{Stream}.

Another thing we’d like to do is to extract one field from each of the index cards in the box and look at the result. Here is an example of that kind of request.

\xtc{What constructors explicitly export a \axiomFun{determinant} operation?
}{
\spadpaste{elt(elt(elt(elt(ops,name="determinant"),origin),sort),unique)\free{o1}}}
}

The first \axiomFun{elt} produces the set of all index cards with name \ttt{determinant}.
The second \axiomFun{elt} extracts the \ttt{origin} component from each index card. Each origin component is the name of a constructor which directly exports the operation represented by the index card. Extracting a component from each index card produces what we call a \ttt{datalist}.
The third \axiomFun{elt}, \ttt{sort}, causes the datalist of origins to be sorted in alphabetic order.
The fourth, \ttt{unique}, causes duplicates to be removed.

Before giving you a more extensive demo of this facility, we now build the necessary domains and packages to implement it. We will introduce a few of our minor conveniences.
\begin{verbatim}
(2) 3
Type: Database IndexCard
\end{verbatim}
\indentrel{-3}

\begin{verbatim}
(3) ["InnerMatrixLinearAlgebraFunctions", "MatrixCategory", "MatrixLinearAlgebraFunctions", "SquareMatrixCategory"]
Type: DataList String
\end{verbatim}
\indentrel{-3}
The Database Constructor

\begin{page}{ugDomainsDatabaseConstructorPage}
{13.13.2. The Database Constructor}
\beginscroll
We work from the top down. First, we define a database, our box of index cards, as an abstract datatype. For sake of illustration and generality, we assume that an index card is some type \texttt{axiom(S)}, and that a database is a box of objects of type \texttt{axiom(S)}. Here is the Axiom program defining the \texttt{pspadtype{Database}} domain.

\beginImportant
\noindent
\tt
1. PI == PositiveInteger
2. Database(S): Exports == Implementation where
3. \hspace{1cm} S: Object with
4. \hspace{1cm} elt: (S, Symbol) -> String
5. \hspace{1cm} display: S -> Void
6. \hspace{1cm} fullDisplay: S -> Void
7. Implementation == add

\tt
8. Exports == with
9. \hspace{1cm} elt: (S, QueryEquation) -> S
10. \hspace{1cm} elt: (S, Symbol) -> DataList String
11. \hspace{1cm} "+": (S, S) -> S
12. \hspace{1cm} "-": (S, S) -> S
13. \hspace{1cm} display: S -> Void
14. \hspace{1cm} fullDisplay: S -> Void
15. \hspace{1cm} fullDisplay: (S, PI) -> Void
16. \hspace{1cm} coerce: S -> OutputForm
17. Implementation == add
\endImportant

The domain constructor takes a parameter \texttt{axiom(S)}, which stands for the class of index cards. We describe an index card later. Here think of an index card as a string which has the eight fields mentioned above.

First, we tell Axiom what operations we are going to require from index cards. We need an \texttt{axiomFun{elt}} to extract the contents of a field (such as \texttt{name} and \texttt{type}) as a string.
For example,
\axiom{c.name} returns a string that is the content of the \axiom{name} field on the index card \axiom{c}.

We need to display an index card in two ways:
\pspadfun{display} shows only the name and type of an operation;
\pspadfun{fullDisplay} displays all fields.
The display operations return no useful information and thus have return type \axiomType{Void}.

Next, we tell Axiom what operations the user can apply to the database.
This part defines our little query language.
The most important operation is
\{\frenchspacing\tt db . field = pattern\} which returns a new database, consisting of all index cards of \{\tt db\} such that the \axiom{field} part of the index card is matched by the string pattern called \axiom{pattern}.
The expression \{\tt field = pattern\} is an object of type \axiomType{QueryEquation} (defined in the next section).

Another \axiomFun{elt} is needed to produce a \pspadtype{DataList} object.
Operation \axiomOp{+} is to merge two databases together;
\axiomOp{-} is used to subtract away common entries in a second database from an initial database.
There are three display functions.
The \pspadfun{fullDisplay} function has two versions: one that prints all the records, the other that prints only a fixed number of records.
A \axiomFun{coerce} to \axiomType{OutputForm} creates a display object.

The \{\tt Implementation\} part of \axiomType{Database} is straightforward.

\beginImportant
\beginverbatim

\tt 1. \ Implementation\ ==\ add
\tt 2. \ s: Symbol
\tt 3. \ Rep \ := \ List\ S
\tt 4. \ elt(db,equation)\ ==\ ...
\tt 5. \ elt(db,key)\ ==\ [x.key\ for\ x\ in\ db]\::DataList(String)
\tt 6. \ display(db)\ ==\ for\ x\ in\ db\ repeat\ display\ x
\tt 7. \ fullDisplay(db)\ ==\ for\ x\ in\ db\ repeat\ fullDisplay\ x
\tt 8. \ fullDisplay(db,\ n,\ m)\ ==\ for\ x\ in\ db\ for\ i\ in\ 1..m\repeat
\tt 9. \ repeat\newline
\endverbatim
\endimportant
The database is represented by a list of elements of \axiom{S} (index cards).

We leave the definition of the first \axiomFun{elt} operation (on line 4) until the next section.

The second \axiomFun{elt} collects all the strings with field name \texttt{key} into a list.

The \axiomFun{display} function and first \axiomFun{fullDisplay} function simply call the corresponding functions from \axiom{S}.

The second \axiomFun{fullDisplay} function provides an efficient way of printing out a portion of a large list.

The \axiomOp{+} is defined by using the existing \spadfunFrom{merge}{List} operation defined on lists, then removing duplicates from the result.

The \axiomOp{-} operation requires writing a corresponding subtraction operation. A package \axiomType{MergeThing} (not shown) provides this.

The \axiomFun{coerce} function converts the database to an \axiomType{OutputForm} by computing the number of index cards.

This is a good example of the independence of the representation of an Axiom object from how it presents itself to the user. We usually do not want to look at a database---but do care how many ‘hits’ we get for a given query. So we define the output representation of a database to be simply the number of index cards our query finds.
The predicate for our search is given by an object of type \pspadtype{QueryEquation}.
Axiom does not have such an object yet so we have to invent it.

\beginImportant
\noindent
{\tt 1.
\hspace{1em} QueryEquation(): \Exports == \Implementation\ where}

{\tt 2.
\hspace{2em} \Exports == \with}

{\tt 3.
\hspace{3em} \equation: \ (Symbol, \ String) \ \to\ \ $}

{\tt 4.
\hspace{4em} \variable: \ $\ \to\ \ Symbol}$

{\tt 5.
\hspace{5em} \value: \ $\ \to\ \ String$

{\tt 6.
\hspace{6em} \Implementation == \add$

{\tt 7.
\hspace{7em} \Implementation == \add$

{\tt 8.
\hspace{8em} \Rep == \ Record(var:Symbol, \ val:String)$

{\tt 9.
\hspace{9em} \equation(x, \ s) == \ [x, \ s]$

{\tt 10.
\hspace{10em} \variable\ q == \ q.var$

{\tt 11.
\hspace{11em} \value\ q == \ q.val$
\endImportant

Axiom converts an input expression of the form \axiom{\it a} = \axiom{\it b} to \axiom{\equation({\it a, b})}. Our equations always have a symbol on the left and a string on the right. The \tt{Exports} part thus specifies an operation \axiomFun{equation} to create a query equation, and \pspadfun{variable} and \pspadfun{value} to select the left- and right-hand sides. The \tt{Implementation} part uses \pspadtype{Record} for a space-efficient representation of an equation.

Here is the missing definition for the \axiomFun{elt} function of \pspadtype{Database} in the last section:

\beginImportant
\noindent
{\tt 1.
\hspace{1em} elt(db, eq) ==}

{\tt 2.
\hspace{2em} field\ :=\ variable\ eq}

{\tt 3.
\hspace{3em} value\ :=\ value\ eq}

{\tt 4.
\hspace{4em} [x for x in db \ where matches?(value, x.field)]}
\endImportant

Recall that a database is represented by a list. Line 4 simply runs over that list collecting all elements such that the pattern (that is, \axiom{value}) matches the selected field of the element.
DataLists

--- ug13.ht ---

Type \texttt{DataList} is a new type invented to hold the result of selecting one field from each of the index cards in the box. It is useful to make datalists extensions of lists---lists that have special \texttt{elt} operations defined on them for sorting and removing duplicates.

\beginImportant

\begin{verbatim}
1. \texttt{DataList(S:OrderedSet) : Exports == Implementation where}
2. \texttt{Exports == ListAggregate(S) with}
3. \texttt{elt: \{(S, "unique") \ ->\ S\}}
4. \texttt{elt: \{(S, "sort") \ ->\ S\}}
5. \texttt{elt: \{(S, "count") \ ->\ NonNegativeInteger\}}
6. \texttt{coerce: List\ S \ ->\ S\}}
7. \texttt{Implementation == List(S) add}
8. \texttt{Rep := List\ S\}}
9. \texttt{elt(x, "unique") == removeDuplicates(x)\}}
10. \texttt{elt(x, "sort") == sort(x)\}}
11. \texttt{elt(x, "count") == \#x\}}
12. \texttt{coerce(x: List\ S) == x :: S\}}
\end{verbatim}
\endImportant

The \texttt{Exports} part asserts that datalists belong to the category \texttt{ListAggregate}. Therefore, you can use all the usual list operations on datalists, such as \spadfun{first}{List}, \spadfun{rest}{List}, and \spadfun{concat}{List}. In addition, datalists have four explicit operations. Besides the three \texttt{elt} operations, there is a \texttt{coerce} operation that creates datalists from lists.
The \tt{Implementation} part needs only to define four functions. All the rest are obtained from \axiomType{List(S)}.

\endscroll
\autobuttons
\end{page}

\begin{page}{Index Cards}{ug13.ht}{13.13.5. Index Cards}
\beginscroll

An index card comes from a file as one long string. We define functions that extract substrings from the long string. Each field has a name that is passed as a second argument to \axiomFun{elt}.

\beginImportant
\noindent
\tt{1. \ IndexCard() == Implementation \ where}
\tt{2. \ Exports == with}
\tt{3. \ elt: (\$, Symbol) -> String}
\tt{4. \ display: \$ -> Void}
\tt{5. \ fullDisplay: \$ -> Void}
\tt{6. \ coerce: String -> \$
\tt{7. \ Implementation == String add\ ...}
\endImportant

We leave the \tt{Implementation} part to the reader. All operations involve straightforward string manipulations.

\endscroll
\autobuttons
\end{page}

\begin{page}{Creating a Database}{ug13.ht}{13.13.5. Creating a Database}
\beginscroll

\end{page}
We must not forget one important operation: one that builds the database in the first place! We'll name it `getDatabase` and put it in a package. This function is implemented by calling the \Lisp{} function \axiom{getBrowseDatabase(s)} to get appropriate information from \Browse{}. This operation takes a string indicating which lines you want from the database: \axiom{"o"} gives you all operation lines, and \axiom{"k"}, all constructor lines. Similarly, \axiom{"c"}, \axiom{"d"}, and \axiom{"p"} give you all category, domain and package lines respectively.

```
1. OperationsQuery(): Exports == Implementation where
2. getDatabase: String -> Database(IndexCard)
3. Implementation == add
4. getDatabase(s) == getBrowseDatabase(s)$Lisp
```

We do not bother creating a special name for databases of index cards. \pspadtype{Database (IndexCard)} will do.

Notice that we used the package \pspadtype{OperationsQuery} to create, in effect, a new kind of domain: \pspadtype{Database(IndexCard)}.

---

Putting It All Together

--- ug13.ht ---

```
using operations and database
```
To create the database facility, you put all these constructors into one file.\footnote{You could use separate files, but we are putting them all together because, organizationally, that is the logical thing to do.}

At the top of the file put \spadcmd{)abbrev} commands, giving the constructor abbreviations you created.

\beginImportant
\noindent
\tt 1. \ )abbrev\ domain\ ICARD\ IndexCard
\tt 2. \ )abbrev\ domain\ QEQUAT\ QueryEquation
\tt 3. \ )abbrev\ domain\ MTHING\ MergeThing
\tt 4. \ )abbrev\ domain\ DLIST\ DataList
\tt 5. \ )abbrev\ domain\ DBASE\ Database
\tt 6. \ )abbrev\ package\ OPQUERY\ OperationsQuery
\endImportant

With all this in \alql.spad, for example, compile it using \begin{verbatim}
)compile alql
\end{verbatim}
and then load each of the constructors:
\begin{verbatim}
)load ICARD QEQUAT MTHING DLIST DBASE OPQUERY
\end{verbatim}

You are ready to try some sample queries.

\endscroll
\autobuttons
\end{page}

---

Example Queries

— ug13.ht —

Our first set of queries give some statistics on constructors in the current Axiom system.

\xtc{How many constructors does Axiom have?}{ugDomainsExamplesPage}

\spadpaste{ks := getDatabase "k"\bound{q1}}
}
\xtc{
Break this down into the number of categories, domains, and packages.
}{\spadpaste{[ks.(kind=k) for k in ["c","d","p"]]}\bound{q3}\free{q1}}
}
\xtc{
What are all the domain constructors that take no parameters?
}{\spadpaste{elt(ks.(kind="d").(nargs="0"),name)}\bound{q4}\free{q1}}
}
\xtc{
How many constructors have ‘‘Matrix’’ in their name?
}{\spadpaste{mk := ks.(name="*Matrix*")}\bound{q5}\free{q1}}
}
\xtc{
What are the names of those that are domains?
}{\spadpaste{elt(mk.(kind="d"),name)}\bound{q6}\free{q5}}
}
\xtc{
How many operations are there in the library?
}{\spadpaste{o := getDatabase "o"\bound{o1}}
}
\xtc{
Break this down into categories, domains, and packages.
}{\spadpaste{[o.(kind=k) for k in ["c","d","p"]]}\free{o1}}
}

The query language is helpful in getting information about a particular operation you might like to apply. While this information can be obtained with \Browse{}, the use of the query database gives you data that you can manipulate in the workspace.

\xtc{
How many operations have ‘‘eigen’’ in the name?
}{\spadpaste{eigens := o.(name="*eigen*")}\bound{eigens}\free{o1}}
}
\xtc{
What are their names?
}{\spadpaste{elt(eigens,name)}\free{eigens}}
}
Where do they come from?

\begin{verbatim}
\spadpaste{elt(elt(elt(eigens,origin),sort),unique) \free{eigens}}
\end{verbatim}

The operations \axiomOp{+} and \axiomOp{-} are useful for constructing small databases and combining them. However, remember that the only matching you can do is string matching. Thus a pattern such as \tt{"*Matrix*"} on the type field matches any type containing \axiomType{Matrix}, \axiomType{MatrixCategory}, \axiomType{SquareMatrix}, and so on.

\xtc{How many operations mention 'Matrix' in their type?}
\begin{verbatim}
\spadpaste{tm := o.(type="*Matrix*") \free{o1}}
\end{verbatim}

\xtc{How many operations come from constructors with 'Matrix' in their name?}
\begin{verbatim}
\spadpaste{fm := o.(origin="*Matrix*") \free{o1}}
\end{verbatim}

\xtc{How many operations are in \axiom{fm} but not in \axiom{tm}?}
\begin{verbatim}
\spadpaste{fm-tm \free{x10 x11}}
\end{verbatim}

\xtc{Display the operations that both mention 'Matrix' in their type and come from a constructor having 'Matrix' in their name.}
\begin{verbatim}
\spadpaste{fullDisplay(fm-\%) \free{x12}}
\end{verbatim}

\xtc{How many operations involve matrices?}
\begin{verbatim}
\spadpaste{m := tm+fm \free{x14}}
\end{verbatim}

\xtc{Display 4 of them.}
\begin{verbatim}
\spadpaste{fullDisplay(m, 202, 205) \free{x14}}
\end{verbatim}

\xtc{How many distinct names of operations involving matrices are there?}
\begin{verbatim}
\spadpaste{elt(elt(elt(m,name),unique),count) \free{x14}}
\end{verbatim}

  \menudownlink{{14.2. The Constructor Page}}
  \menudownlink{{14.3. Miscellaneous Features of Browse}}
\end{menu}
\endscroll
\autobuttons
\end{page}
The Front Page: Searching the Library

To enter \Browse{}, click on \textbf{Browse} on the top level page of Hyperdoc to get the \textit{front page} of \Browse{}. Axiom does a case-insensitive search for a match. Thus \texttt{matrix} is just as good as \texttt{Matrix}, has the same effect as \texttt{MaTrix}, and so on. We recommend that you generally use small letters for names however. A search string with only capital letters has a special meaning (see \downlink{‘Capitalization Convention’}{ugBrowseCapitalizationConventionPage} in Section 14.3.3\ignore{ugBrowseCapitalizationConvention}).

Click on \UpBitmap{} to return to the \Browse{} front page.

Use the symbol ‘\texttt{*}’ in search strings as a \spadgloss{wild card}. A wild card matches any substring, including the empty string. For example, enter the search string \texttt{*matrix*} into the input
area and click on {\bf Constructors}. To get only categories, domains, or packages, rather than all constructors, you can click on the corresponding button to the right of {\bf Constructors}.

What you get is a table of all constructors whose names contain the string ‘‘{\tt matrix}.’’

All constructors containing the string are listed, whether \spadglossSee{exposed}{expose} or \spadglossSee{unexposed}{expose}. You can hide the names of the unexposed constructors by clicking on the {\it *=}{\bf unexposed} button in the {\it Views} panel at the bottom of the window. (The button will change to {\bf exposed} {\it only}.)

One of the names in this table is \axiomType{Matrix}. Click on \axiomType{Matrix}. What you get is again the constructor page for \axiomType{Matrix}. As you see, \Browse{} gives you a large network of information in which there are many ways to reach the same pages.

Again click on the \UpBitmap{} to return to the table of constructors whose names contain {\tt matrix}. Below the table is a {\it Views} panel. This panel contains buttons that let you view constructors in different ways. To learn about views of constructors, skip to \downlink{‘‘Views Of Constructors’’}{ugBrowseViewsOfConstructorsPage} in Section 14.2.3\ignore{ugBrowseViewsOfConstructors}.

Click on \UpBitmap{} to return to the \Browse{} front page.

\subsubsection{Operations}

Enter {\tt *matrix} into the input area and click on {\bf Operations}. This time you get a table of {\it operations} whose names end with {\tt matrix} or {\tt Matrix}.

If you select an operation name, you go to a page describing all the operations in Axiom of that name. At the bottom of an operation page is another kind of {\it Views} panel, one for operation pages. To learn more about these views, skip to \downlink{‘‘Views of Operations’’}{ugBrowseViewsOfOperationsPage} in Section 14.3.2\ignore{ugBrowseViewsOfOperations}.

Click on \UpBitmap{} to return to the \Browse{} front page.

\subsection{Attributes}

This button gives you a table of attribute names that match the search string. Enter the search string {\tt *} and click on {\bf Attributes} to get a list of all system attributes.
Click on \UpBitmap{} to return to the \Browse{} front page.

Again there is a \{\it Views\} panel at the bottom with buttons that let you view the attributes in different ways.

\subsubsection{General}

This button does a general search for all constructor, operation, and attribute names matching the search string. Enter the search string \allowbreak \{tt *matrix*\} into the input area. Click on \{bf General\} to find all constructs that have \{tt matrix\} as a part of their name.

The summary gives you all the names under a heading when the number of entries is less than 10.

Click on \UpBitmap{} to return to the \Browse{} front page.

\subsubsection{Documentation}

Again enter the search key \{tt *matrix*\} and this time click on \{bf Documentation\}.

This search matches any constructor, operation, or attribute name whose documentation contains a substring matching \{tt matrix\}.

Click on \UpBitmap{} to return to the \Browse{} front page.

\subsubsection{Complete}

This search combines both \{bf General\} and \{bf Documentation\}.

\endscroll
\autobuttons
\end{page}
In this section we look in detail at a constructor page for domain \axiomType{Matrix}.
Enter {\tt matrix} into the input area on the main \Browse{} page and click on {\bf Constructors}.

The header part tells you that \axiomType{Matrix} has abbreviation \axiomType{MATRIX} and one argument called {\tt R} that must be a domain of category \axiomType{Ring}.
Just what domains can be arguments of \axiomType{Matrix}? To find this out, click on the {\tt R} on the second line of the heading.
What you get is a table of all acceptable domain parameter values of {\tt R}, or a table of \spadgloss{rings} in Axiom.

Click on \UpBitmap{} to return to the constructor page for \axiomType{Matrix}.
	\texht{\newpage}{}

If you have access to the source code of Axiom, the third line of the heading gives you the name of the source file containing the definition of \axiomType{Matrix}.
Click on it to pop up an editor window containing the source code of \axiomType{Matrix}.

We recommend that you leave the editor window up while working through this chapter as you occasionally may want to refer to it.

Constructor Page Buttons

\begin{page}{ugBrowseDomainButtonsPage}{14.2.1. Constructor Page Buttons}
\beginscroll

We examine each button on this page in order.

\labelSpace{2pc}

\subsubsection{Description}

Click here to bring up a page with a brief description of constructor \axiomType{Matrix}.
If you have access to system source code, note that these comments can be found directly over the constructor definition.

\subsubsection{Operations}

Click here to get a table of operations exported by \axiomType{Matrix}.
You may wish to widen the window to have multiple columns as below.

If you click on an operation name, you bring up a description page for the operations. For a detailed description of these pages, skip to \downlink{``Views of Operations''}{ugBrowseViewsOfOperationsPage} in Section 14.3.2\ignore{ugBrowseViewsOfOperations}.

\subsubsection{Attributes}

Click here to get a table of the two attributes exported by \axiomType{Matrix}:
\spadatt{\texht{finiteAggregate}} and \spadatt{shallowlyMutable}.
These are two computational properties that result from \axiomType{Matrix} being regarded as a data structure.

\subsubsection{Examples}

Click here to get an \{\it examples page\} with examples of operations to create and manipulate matrices.

Read through this section.
Try selecting the various buttons.
Notice that if you click on an operation name, such as \spadfunFrom{new}{Matrix}, you bring up a description page for that operation from \axiomType{Matrix}.

Example pages have several examples of Axiom commands. Each example has an active button to its left. Click on it! A pre-computed answer is pasted into the page immediately following the command. If you click on the button a second time, the answer disappears. This button thus acts as a toggle: ‘now you see it; now you don’t.’

Note also that the Axiom commands themselves are active. If you want to see Axiom execute the command, then click on it! A new Axiom window appears on your screen and the command is executed.

At the end of the page is generally a menu of buttons that lead you to further sections. Select one of these topics to explore its contents.

\subsection{Exports}

Click here to see a page describing the exports of \axiomType{Matrix} exactly as described by the source code.

As you see, \axiomType{Matrix} declares that it exports all the operations and attributes exported by category \axiomType{MatrixCategory(R, Row, Col)}. In addition, two operations, \axiomFun{diagonalMatrix} and \axiomFun{inverse}, are explicitly exported.

To learn a little about the structure of Axiom, we suggest you do the following exercise. Otherwise, click on \UpButton{} and go on to the next section. \axiomType{Matrix} explicitly exports only two operations. The other operations are thus exports of \axiomType{MatrixCategory}. In general, operations are usually not explicitly exported by a domain. Typically they are \spadglossSee{inherited}{inherit} from several different categories.

Let’s find out from where the operations of \axiomType{Matrix} come.

\begin{itemize}
\item Click on \bf{MatrixCategory}, then on \bf{Exports}. Here you see that \bf{MatrixCategory} explicitly exports many matrix operations. Also, it inherits its operations from
\item[2. ] Click on \textbf{TwoDimensionalArrayCategory}, then on \textbf{Exports}. Here you see explicit operations dealing with rows and columns. In addition, it inherits operations from \axiomType{HomogeneousAggregate}.

%\item Click on \textbf{HomogeneousAggregate}, then on \textbf{Exports}. %And so on.
%If you continue doing this, eventually you will

\item[3. ] Click on \UpBitmap{} and then click on \textbf{Object}, then on \textbf{Exports}, where you see there are no exports.

\item[4. ] Click on \UpBitmap{} repeatedly to return to the constructor page for \axiomType{Matrix}.

\enditems
\indent{0}
\subsection{Related Operations}
Click here bringing up a table of operations that are exported by \spadglossSee{packages}{package} but not by \axiomType{Matrix} itself.

To see a table of such packages, use the \textbf{Relatives} button on the \textbf{Cross Reference} page described next.

\endscroll
\autobuttons
\end{page}

Cross Reference

— ug14.ht —

\begin{page}{ugBrowseCrossReferencePage}{14.2.2. Cross Reference}
\beginscroll
Click on the \textbf{Cross Reference} button on the main constructor page for \axiomType{Matrix}.
This gives you a page having various cross reference information stored under the respective buttons.

\endscroll
\autobuttons
\end{page}
\subsubsection{Parents}

The parents of a domain are the same as the categories mentioned under the \bf{Exports} button on the first page. Domain \axiomType{Matrix} has only one parent but in general a domain can have any number.

\subsubsection{Ancestors}

The \spadglossSee{ancestors}{ancestor} of a constructor consist of its parents, the parents of its parents, and so on. Did you perform the exercise in the last section under \bf{Exports}? If so, you see here all the categories you found while ascending the \bf{Exports} chain for \axiomType{Matrix}.

\subsubsection{Relatives}

The \spadglossSee{relatives}{relative} of a domain constructor are package constructors that provide operations in addition to those \spadglossSee{exported}{export} by the domain.

Try this exercise.
\indent{4}
\begin{itemlist}
\item[1.] Click on \bf{ Relatives}, bringing up a list of \spadglossSee{packages}{package}.
\item[2.] Click on \bf{ LinearSystemMatrixPackage} bringing up its constructor page.\footnote{You may want to widen your Hyperdoc window to make what follows more legible.}
\item[3.] Click on \bf{ Operations}. Here you see \axiomFun{rank}, an operation also exported by \axiomType{Matrix} itself.
\item[4.] Click on \bf{ rank}. This \spadfunFrom{rank}{LinearSystemMatrixPackage} has two arguments and thus is different from the \spadfunFrom{rank}{Matrix} from \axiomType{Matrix}.
\item[5.] Click on \up\ to return to the list of operations for the package \axiomType{LinearSystemMatrixPackage}.
\item[6.] Click on \bf{ solve} to bring up a \spadfunFrom{solve}{LinearSystemMatrixPackage} for linear systems of equations.
\item[7.] Click on \up\ several times to return to the cross
reference page for \axiomType{Matrix}.
\enditems
\indent{0}

\subsubsection{Dependents}

The \spadglossSee{dependents}{dependent} of a constructor are those \spadglossSee{domains}{domain} or \spadglossSee{packages}{package} that mention that constructor either as an argument or in its \spadglossSee{exports}{export}.

If you click on \bf Dependents two entries may surprise you: \axiomType{RectangularMatrix} and \axiomType{SquareMatrix}. This happens because \axiomType{Matrix}, as it turns out, appears in signatures of operations exported by these domains.

\subsubsection{Lineage}

The term \spadgloss{lineage} refers to the \it search order\ for functions.

If you are an expert user or curious about how the Axiom system works, try the following exercise. Otherwise, you best skip this button and go on to \bf Clients.

Clicking on \bf Lineage gives you a list of domain constructors: \axiomType{InnerIndexedTwoDimensionalArray}, \aliascon{MatrixCategory\&}{MATCAT-}, \aliascon{TwoDimensionalArrayCategory\&}{ARR2CAT-}, \aliascon{HomogeneousAggregate\&}{HOAGG-}, \aliascon{Aggregate\&}{AGG-}.

What are these constructors and how are they used?

We explain by an example. Suppose you create a matrix using the interpreter, then ask for its \axiom{rank}. Axiom must then find a function implementing the \axiom{rank} operation for matrices. The first place Axiom looks for \axiom{rank} is in the \axiomType{Matrix} domain.

If not there, the lineage of \axiomType{Matrix} tells Axiom where else to look. Associated with the matrix domain are five other lineage domains. Their order is important. Axiom first searches the first one, \axiomType{InnerIndexedTwoDimensionalArray}. If not there, it searches the second \aliascon{MatrixCategory\&}{MATCAT-}. And so on.

Where do these \it lineage constructors\ come from? The source code for \axiomType{Matrix} contains this syntax for the \spadgloss{function body} of \axiomType{Matrix}:\footnote{\axiomType{InnerIndexedTwoDimensionalArray} is a special domain implemented for matrix-like domains to provide
efficient implementations of \twodim{} arrays.
For example, domains of category \axiomType{TwoDimensionalArrayCategory}
can have any integer as their \spad{minIndex}.
Matrices and other members of this special ‘‘inner’’ array have their
\spad{minIndex} defined as \spad{1}.
\begin{verbatim}
InnerIndexedTwoDimensionalArray(R,mnRow,mnCol,Row,Col)
    add ...
\end{verbatim}
where the ‘‘\tt{...}’’ denotes all the code that follows.
In English, this means:
‘‘The functions for matrices are defined as those from
\axiomType{InnerIndexedTwoDimensionalArray} domain augmented by those
defined in ‘‘\tt{...}’’,’’ where the latter take precedence.
This explains \axiomType{InnerIndexedTwoDimensionalArray}.
The other names, those with names ending with an ampersand \axiomSyntax{\&} are
\spadglossSee{default packages}{default package}
for categories to which \axiomType{Matrix} belongs.
Default packages are ordered by the notion of ‘‘closest ancestor.’’

\subsubsection{Clients}
A client of \axiomType{Matrix} is any constructor that uses
\axiomType{Matrix} in its implementation.
For example, \axiomType{Complex} is a client of \axiomType{Matrix}; it
exports several operations that take matrices as arguments or return
matrices as values.\footnote{A constructor is a client of
\axiomType{Matrix} if it handles any matrix.
For example, a constructor having internal (unexported) operations
dealing with matrices is also a client.}

\subsubsection{Benefactors}
A \spadgloss{benefactor} of \axiomType{Matrix} is any constructor that
\axiomType{Matrix} uses in its implementation.
This information, like that for clients, is gathered from run-time
structures.\footnote{The benefactors exclude constructors such as
\axiomType{PrimitiveArray} whose operations macro-expand and so vanish
from sight!}

Cross reference pages for categories have some different buttons on
them. Starting with the constructor page of \axiomType{Matrix}, click on
\axiomType{Ring} producing its constructor page.
Click on \bf{Cross Reference},
producing the cross-reference page for \axiomType{Ring}.
Here are buttons \bf{Parents} and \bf{Ancestors} similar to the notion
for domains, except for categories the relationship between parent and
child is defined through \spadgloss{category extension}. 
\subsubsection{Children}

Category hierarchies go both ways. There are children as well as parents. A child can have any number of parents, but always at least one. Every category is therefore a descendant of exactly one category: \texttt{Object}.

\subsubsection{Descendants}

These are children, children of children, and so on.

Category hierarchies are complicated by the fact that categories take parameters. Where a parameterized category fits into a hierarchy \texttt{may} depend on values of its parameters. In general, the set of categories in Axiom forms a directed acyclic graph, that is, a graph with directed arcs and no cycles.

\subsubsection{Domains}

This produces a table of all domain constructors that can possibly be rings (members of category \texttt{Ring}). Some domains are unconditional rings. Others are rings for some parameters and not for others. To find out which, select the \texttt{Conditions} button in the views panel. For example, \texttt{DirectProduct(n, R)} is a ring if \texttt{R} is a ring.

------

Views Of Constructors

— \texttt{ug14.ht} —

Below every constructor table page is a \texttt{Views} panel.
As an example, click on \textbf{Cross Reference} from the constructor page of \texttt{axiomType{Matrix}}, then on \textbf{Benefactors} to produce a short table of constructor names.

The \textit{Views} panel is at the bottom of the page. Two items, \textit{names} and \textit{conditions}, are in italics. Others are active buttons. The active buttons are those that give you useful alternative views on this table of constructors. Once you select a view, you notice that the button turns off (becomes italicized) so that you cannot reselect it.

\subsection{names}

This view gives you a table of names. Selecting any of these names brings up the constructor page for that constructor.

\subsection{abbrs}

This view gives you a table of abbreviations, in the same order as the original constructor names. Abbreviations are in capitals and are limited to 7 characters. They can be used interchangeably with constructor names in input areas.

\subsection{kinds}

This view organizes constructor names into the three kinds: categories, domains and packages.

\subsection{files}

This view gives a table of file names for the source code of the constructors in alphabetic order after removing duplicates.

\subsection{parameters}

This view presents constructors with the arguments. This view of the benefactors of \texttt{axiomType{Matrix}} shows that \texttt{axiomType{Matrix}} uses as many as five different \texttt{axiomType{List}} domains in its implementation.

\subsection{filter}

This button is used to refine the list of names or abbreviations. Starting with the \textit{names} view, enter \texttt{m*} into the input area and click on \textbf{filter}. You then get a shorter table with only the names beginning with \texttt{m}. 
\subsubsection{documentation}

This gives you documentation for each of the constructors.

\subsubsection{conditions}

This page organizes the constructors according to predicates. The view is not available for your example page since all constructors are unconditional. For a table with conditions, return to the \texttt{Cross Reference} page for \texttt{Matrix}, click on \texttt{Ancestors}, then on \texttt{Conditions} in the view panel. This page shows you that \texttt{CoercibleTo(OutputForm)} and \texttt{SetCategory} are ancestors of \texttt{Matrix(R)} only if \texttt{R} belongs to category \texttt{SetCategory}.

\end{scroll}
\autobuttons
\end{page}

---

**Giving Parameters to Constructors**

--- ug14.ht ---

\begin{page}{ugBrowseGivingParametersPage}
{14.2.4. Giving Parameters to Constructors}
\beginscroll

\%*********************************************************************

Notice the input area at the bottom of the constructor page. If you leave this blank, then the information you get is for the domain constructor \texttt{Matrix(R)}, that is, \texttt{Matrix} for an arbitrary underlying domain \texttt{R}.

In general, however, the exports and other information \{\texttt{it do}\} usually depend on the actual value of \texttt{R}.

For example, \texttt{Matrix} exports the \texttt{inverse} operation only if the domain \texttt{R} is a \texttt{Field}.

To see this, try this from the main constructor page:

\indent{4}
\beginitem
\item Enter \texttt{Integer} into the input area at the bottom of the page.
\enditem
\end{scroll}
\end{page}
\item[2. ] Click on \bf{Operations}, producing a table of operations. Note the number of operation names that appear at the top of the page.

\item[3. ] Click on \Up{} to return to the constructor page.

\item[4. ] Use the \texttt{fbox{Delete}} or \texttt{fbox{Backspace}} keys to erase \tt{Integer} from the input area.

\item[5. ] Click on \bf{Operations} to produce a new table of operations. Look at the number of operations you get. This number is greater than what you had before. Find, for example, the operation \axiomFun{inverse}.

\item[6. ] Click on \bf{inverse} to produce a page describing the operation \axiomFun{inverse}. At the bottom of the description, you notice that the \bf{Conditions} line says \tt{R} has \axiomType{Field}.'' This operation is \bf{not} exported by \axiomType{Matrix(Integer)} since \axiomType{Integer} is not a \spadgloss{field}.

Try putting the name of a domain such as \axiomType{Fraction Integer} (which is a field) into the input area, then clicking on \bf{Operations}. As you see, the operation \axiomFun{inverse} is exported.

\enditems
\indent{0}
\endscroll
\autobuttons
\end{page}

---

Miscellaneous Features of Browse

— ug14.ht —

\begin{page}{ugBrowseMiscellaneousFeaturesPage}
{14.3. Miscellaneous Features of Browse}
\beginscroll
\labelSpace{4pc}
\begin{menu}
\menuDownlink{{14.3.1. The Description Page for Operations}}
\endmenu
\end{scroll}
\autobuttons
\end{page}
The Description Page for Operations

From the constructor page of \texttt{Matrix}, click on \textbf{Operations} to bring up the table of operations for \texttt{Matrix}.

Find the operation \textbf{inverse} in the table and click on it. This takes you to a page showing the documentation for this operation.

Here is the significance of the headings you see.

\subsection{Arguments}

This lists each of the arguments of the operation in turn, paraphrasing the \texttt{signature} of the operation. As for signatures, a \texttt{\$} is used to designate \texttt{this domain}, that is, \texttt{Matrix(R)}.

\subsection{Returns}

This describes the return value for the operation, analogous to the \textbf{Arguments} part.

\subsection{Origin}

This tells you which domain or category explicitly exports the operation.

In this example, the domain itself is the \texttt{Origin}.
\subsection{Conditions}

This tells you that the operation is exported by \axiomType{Matrix(R)} only if
\tt{R} has \axiomType{Field},'' that is, \tt{R} is a member of category \axiomType{Field}.''

When no \bf{Conditions} part is given, the operation is exported for
all values of \tt{R}.

\subsection{Description}

Here are the \axiomSyntax{++} comments
that appear in the source code of its \it{Origin}, here \axiomType{Matrix}.
You find these comments in the source code for \axiomType{Matrix}.

Click on \UpBitmap{} to return to the table of operations.
Click on \bf{map}.
Here you find three different operations named \axiomFun{map}.
This should not surprise you.
Operations are identified by name and \spadgloss{signature}.
There are three operations named \axiomFun{map}, each with
different signatures.
What you see is the \it{descriptions} view of the operations.
If you like, select the button in the heading of one of these
descriptions to get \it{only} that operation.

\subsection{Where}

This part qualifies domain parameters mentioned in the arguments to the
operation.

---

Views of Operations

--- ug14.ht ---

We suggest that you go to the constructor page for \axiomType{Matrix}
and click on \{\bf Operations\} to bring up a table of operations with a \{\it Views\} panel at the bottom.

\subsection{names}

This view lists the names of the operations. Unlike constructors, however, there may be several operations with the same name. The heading for the page tells you the number of unique names and the number of distinct operations when these numbers are different.

\subsection{filter}

As for constructors, you can use this button to cut down the list of operations you are looking at. Enter, for example, \{\tt m*\} into the input area to the right of \{\bf filter\} then click on \{\bf filter\}. As usual, any logical expression is permitted. For example, use
\begin{verbatim}
*! or *?
\end{verbatim}
to get a list of destructive operations and predicates.

\subsection{documentation}

This gives you the most information: a detailed description of all the operations in the form you have seen before. Every other button summarizes these operations in some form.

\subsection{signatures}

This views the operations by showing their signatures.

\subsection{parameters}

This views the operations by their distinct syntactic forms with parameters.

\subsection{origins}

This organizes the operations according to the constructor that explicitly exports them.

\subsection{conditions}

This view organizes the operations into conditional and unconditional operations.
\subsubsection{usage}

This button is only available if your user-level is set to \textit{development}. The \textbf{usage} button produces a table of constructors that reference this operation. \footnote{Axiom requires an especially long time to produce this table, so anticipate this when requesting this information.}

\subsubsection{implementation}

This button is only available if your user-level is set to \textit{development}. If you enter values for all domain parameters on the constructor page, then the \textbf{implementation} button appears in place of the \textbf{conditions} button. This button tells you what domains or packages actually implement the various operations. \footnote{This button often takes a long time; expect a delay while you wait for an answer.}

With your user-level set to \textit{development}, we suggest you try this exercise. Return to the main constructor page for \texttt{Matrix}, then enter \texttt{Integer} into the input area at the bottom as the value of \texttt{R}. Then click on \textbf{Operations} to produce a table of operations. Note that the \textbf{conditions} part of the \textit{Views} table is replaced by \textbf{implementation}. Click on \textbf{implementation}. After some delay, you get a page describing what implements each of the matrix operations, organized by the various domains and packages.

\subsubsection{generalize}

This button only appears for an operation page of a constructor involving a unique operation name.

From an operations page for \texttt{Matrix}, select any operation name, say \texttt{rank}. In the views panel, the \textbf{filter} button is replaced by \textbf{generalize}. Click on it!

\footnote{If there were more than 10 operations of the name, you get instead a page with a \textit{Views} panel at the bottom and the message to \textbf{Select a view below}.}

To get the descriptions of all these operations as mentioned above, select the \textbf{description} button.
This button only appears on an operation page resulting from a search from the front page of \Browse{} or from selecting \bf generalize{} from an operation page for a constructor.

Note that the \bf filter{} button in the \it Views{} panel is replaced by \bf all domains{}. Click on it to produce a table of \it all domains{} or packages that export a \axiomFun{rank} operation.

We note that this table specifically refers to all the \axiomFun{rank} operations shown in the preceding page. Return to the descriptions of all the \axiomFun{rank} operations and select one of them by clicking on the button in its heading. Select \bf all domains{}. As you see, you have a smaller table of constructors. When there is only one constructor, you get the constructor page for that constructor.

---

Capitalization Convention

When entering search keys for constructors, you can use capital letters to search for abbreviations. For example, enter \tt UTS{} into the input area and click on \bf Constructors{}. Up comes a page describing \axiomType{UnivariateTaylorSeries} whose abbreviation is \axiomType{UTS}.

Constructor abbreviations always have three or more capital letters. For short constructor names (six letters or less), abbreviations
are not generally helpful as their abbreviation is typically the constructor name in capitals.
For example, the abbreviation for \texttt{Matrix} is \texttt{MATRIX}.

Abbreviations can also contain numbers.
For example, \texttt{POLY2} is the abbreviation for constructor \texttt{PolynomialFunctions2}.
For default packages, the abbreviation is the same as the abbreviation for the corresponding category with the \texttt{	extbackslash k}' replaced by \texttt{-}'.
For example, for the category default package \texttt{MatrixCategory\&\texttt{MATCAT-}} the abbreviation is \texttt{MATCAT-} since the corresponding category \texttt{MatrixCategory} has abbreviation \texttt{MATCAT}.
Chapter 18

Users Guide Chapter 15 (ug15.ht)

What’s New in Axiom Version 2.0

— ug15.ht —

Many things have changed in this new version of Axiom and we describe many of the more important topics here.

\begin{page}{ugWhatsNewPage}{15. What’s New in Axiom Version 2.0}

Important Things to Read First

---

If you have any private `.spad` files (that is, library files which were not shipped with Axiom) you will need to recompile them. For example, if you wrote the file `regress.spad` then you should issue `compile regress.spad` before trying to use it.

The internal representation of `Union` has changed. This means that Axiom data saved with Release 1.x may not be readable by this Release. If you cannot recreate the saved data by recomputing in Release 2.0, please contact NAG for assistance.

---

The NAG Library Link

⇒ "notitle" (htxl1) 3.63 on page 845
⇒ "notitle" (nagDocumentationPage) 18 on page 2495
⇒ "notitle" (nagLinkUsagePage) 18 on page 2498

⇒ "notitle" (generalFortranPage) 18 on page 2505
⇒ "notitle" (nagTechnicalPage) 18 on page 2530

---

The `naglib()` link allows you to call NAG Fortran routines from within Axiom, passing Axiom objects as parameters and getting them back as results.

The `naglib()` and, consequently, the link are divided into Chapters, which cover different areas of numerical analysis. The
statistical and sorting \textit{chapters} of the Library, however, are not included in the link and various support and utility routines (mainly the F06 and X \textit{chapters}) have been omitted.

Each \textit{chapter} has a short (at most three-letter) name; for example, the \textit{chapter} devoted to the solution of ordinary differential equations is called D02. When using the link via the \texttt{Hyperdoc interface}, you will be presented with a complete menu of these \textit{chapters}. The names of individual routines within each \textit{chapter} are formed by adding three letters to the \textit{chapter} name, so for example the routine for solving ODEs by Adams method is called \texttt{\textbackslash axiomFunFrom\{d02cjf\}\{NagOrdinaryDifferentialEquationsPackage\}}.

\textbf{Interpreting NAG Documentation}

\begin{quote}
\begin{itemize}
  \item “notitle” (\texttt{manpageXXintro}) 22.1 on page 2727
  \item “notitle” (\texttt{manpageXXonline}) 22.1 on page 2703
  \item “notitle” (\texttt{FoundationLibraryDocPage}) 3.1 on page 125
  \item “notitle” (\texttt{aspSectionPage}) 18 on page 2501
\end{itemize}
\end{quote}

Information about using the \texttt{\textbackslash naglib{}} in general, and about using individual routines in particular, can be accessed via Hyperdoc. This documentation refers to the Fortran routines directly; the purpose of this subsection is to explain how this corresponds to the Axiom routines.
For general information about the \naglib{} users should consult \downlink{Essential Introduction to the NAG Foundation Library}{manpageXXintro}. The documentation is in ASCII format, and a description of the conventions used to represent mathematical symbols is given in \downlink{Introduction to NAG On-Line Documentation}{manpageXXonline}. Advice about choosing a routine from a particular \em chapter can be found in the \downlink{Chapter Documents}{FoundationLibraryDocPage}.

\subsection{Correspondence Between Fortran and Axiom types}

The NAG documentation refers to the Fortran types of objects; in general, the correspondence to Axiom types is as follows.

\begin{itemize}
\item Fortran INTEGER corresponds to Axiom \axiomType{Integer}.
\item Fortran DOUBLE PRECISION corresponds to Axiom \axiomType{DoubleFloat}.
\item Fortran COMPLEX corresponds to Axiom \axiomType{Complex DoubleFloat}.
\item Fortran LOGICAL corresponds to Axiom \axiomType{Boolean}.
\item Fortran CHARACTER*(*) corresponds to Axiom \axiomType{String}.
\end{itemize}

(Exceptionally, for NAG EXTERNAL parameters -- ASPs in link parlance -- REAL and COMPLEX correspond to \axiomType{MachineFloat} and \axiomType{MachineComplex}, respectively; see \downlink{``Providing values for Argument Subprograms''}{aspSectionPage} in Section 15.3.3\ignore{aspSection}.)

The correspondence for aggregates is as follows.

\begin{itemize}
\item A one-dimensional Fortran array corresponds to an Axiom \texttt{Matrix} with one column.
\item A two-dimensional Fortran ARRAY corresponds to an Axiom \texttt{Matrix}.
\item A three-dimensional Fortran ARRAY corresponds to an Axiom \texttt{ThreeDimensionalMatrix}.
\end{itemize}

Higher-dimensional arrays are not currently needed for the \naglib{}. Arguments which are Fortran FUNCTIONs or SUBROUTINEs correspond to special ASP domains in Axiom. See
Providing values for Argument Subprograms''} in Section 15.3.

Classification of NAG parameters

NAG parameters are classified as belonging to one (or more) of the following categories: \{Input\}, \{Output\}, \{Workspace\} or \{External\} procedure. Within \{External\} procedures a similar classification is used, and parameters may also be \{Dummies\}, or \{User Workspace\} (data structures not used by the NAG routine but provided for the convenience of the user).

When calling a NAG routine via the link the user only provides values for \{Input\} and \{External\} parameters.

The order of the parameters is, in general, different from the order specified in the naglib{} documentation. The Browser description for each routine helps in determining the correspondence. As a rule of thumb, \{Input\} parameters come first followed by \{Input/Output\} parameters. The \{External\} parameters are always found at the end.

IFAIL

NAG routines often return diagnostic information through a parameter called \{ifail\}. With a few exceptions, the principle is that on input \{ifail\} takes one of the values $-1,0,1$. This determines how the routine behaves when it encounters an error:

\begin{itemize}
  \item A value of 1 causes the NAG routine to return without printing an error message;
  \item A value of 0 causes the NAG routine to print an error message and abort;
  \item A value of -1 causes the NAG routine to return and print an error message.
\end{itemize}

The user is STRONGLY ADVISED to set \{ifail\} to \{ifail\} when using the link. If \{ifail\} has been set to \{ifail\} or \{ifail\}, then its value on output will determine the possible cause of any error. A value of \{ifail\} indicates successful completion, otherwise it provides an index into a table of diagnostics provided as part of the routine documentation (accessible via \{Browse\}).
Using the Link

⇒ “notitle” (htxl1) 3.63 on page 845
— ug15.ht —

\begin{page}{nagLinkUsagePage}{15.3.2. Using the Link}
\beginscroll

The easiest way to use the link is via the
\downlink{Hyperdoc interface}{htxl1}. You will be presented with a set of fill-in forms where
you can specify the parameters for each call. Initially, the forms
contain example values, demonstrating the use of each routine (these,
in fact, correspond to the standard NAG example program for the
routine in question). For some parameters, these values can provide
reasonable defaults; others, of course, represent data. When you
change a parameter which controls the size of an array, the data in
that array are reset to a ‘‘neutral’’ value -- usually zero.

When you are satisfied with the values entered, clicking on the
‘‘Continue’’ button will display the Axiom command needed to
run the chosen NAG routine with these values. Clicking on the
‘‘Do It’’ button will then cause Axiom to execute this command
and return the result in the parent Axiom session, as described
below. Note that, for some routines, multiple HyperDoc ‘‘pages’’ are
required, due to the structure of the data. For these, returning to
an earlier page causes HyperDoc to reset the later pages (this is a
general feature of HyperDoc); in such a case, the simplest way to
repeat a call, varying a parameter on an earlier page, is probably to
modify the call displayed in the parent session.

An alternative approach is to call NAG routines directly in your
normal Axiom session (that is, using the Axiom
interpreter). Such calls return an
object of type \axiomType{Result}. As not
all parameters in the underlying NAG routine are required in the
Axiom call (and the parameter ordering may be different), before
calling a NAG routine you should consult the description of the
Axiom operation in the Browser. (The quickest route to this
is to type the routine name, in lower case, into the Browser’s
input area, then click on (\tt Operations{}.) The parameter names
used coincide with NAG’s, although they will appear here in lower
case. Of course, it is also possible to become familiar with the
Axiom form of a routine by first using it through the
As an example of this mode of working, we can find a zero of a function, lying between 3 and 4, as follows:
}
\spadpaste{answer:=c05adf(3.0,4.0,1.0e-5,0.0,-1,sin(X)::ASP1(F))
\bound{answer} }
\xtc{
By default, \texttt{Result} only displays the type of returned values, since the amount of information returned can be quite large. Individual components can be examined as follows:
}
\spadpaste{answer . x\free{answer}}
\xtc{ }
\spadpaste{answer . ifail\free{answer}}
\xtc{
In order to avoid conflict with names defined in the workspace, you can also get the values by using the \texttt{String} type (the interpreter automatically coerces them to \texttt{Symbol})
}
\spadpaste{answer "x"\free{answer}}
\xtc{
It is possible to have Axiom display the values of scalar or array results automatically. For more details, see the commands \texttt{showScalarValues\{Result\}} and \texttt{showArrayValues\{Result\}}.
}
\xtc{
There is also a \texttt{.input} file for each NAG routine, containing Axiom interpreter commands to set up and run the standard NAG example for that routine.
}
\spadpaste{)read c05adf.input}
\begin{verbatim}
(1) [ifail: Integer, x: DoubleFloat]
Type: Result
\end{verbatim}

\begin{verbatim}
(2) 3.14159265545896
Type: DoubleFloat
\end{verbatim}

\begin{verbatim}
(3) 0
Type: Integer
\end{verbatim}

\begin{verbatim}
(4) 3.14159265545896
\end{verbatim}
Providing values for Argument Subprograms

⇒ “notitle” (generalFortranPage) 18 on page 2505

--- ug15.ht ---
There are a number of ways in which users can provide values for argument subprograms (ASPs). At the top level the user will see that NAG routines require an object from the \axiomType{Union} of a \axiomType{Filename} and an ASP.

For example \axiomFun{c05adf} requires an object of type \axiomType{Union}(fn: \axiomType{FileName}, fp: \axiomType{Asp1 F})

The user thus has a choice of providing the name of a file containing Fortran source code, or of somehow generating the ASP within Axiom. If a filename is specified, it is searched for in the \textit{local} machine, i.e., the machine that Axiom is running on.

The \axiomType{FortranExpression} domain is used to represent expressions which can be translated into Fortran under certain circumstances. It is very similar to \axiomType{Expression} except that only operators which exist in Fortran can be used, and only certain variables can occur. For example the instantiation \axiomType{FortranExpression([X],[M],MachineFloat)} is the domain of expressions containing the scalar \axiom{X} and the array \axiom{M}.

This allows us to create expressions like:

\spadpaste{f : FortranExpression([X],[M],MachineFloat) := sin(X)+M[3,1]}

but not

\spadpaste{f : FortranExpression([X],[M],MachineFloat) := sin(M)+Y}

Those ASPs which represent expressions usually export a \axiomFun{coerce} from an appropriate instantiation of \axiomType{FortranExpression} (or perhaps \axiomType{Vector FortranExpression} etc.). For convenience there are also rejections from appropriate instantiations of \axiomType{Expression}, \axiomType{Polynomial} and \axiomType{Fraction Polynomial}.

Those ASPs which represent expressions usually export a
\text{\texttt{FortranCode}}} allows us to build arbitrarily complex ASPs via a kind of pseudo-code. It is described fully in \downlink{``General Fortran-generation utilities in Axiom''}{generalFortranPage} in Section 15.3.4\ignore{generalFortran}.

Every ASP exports two \axiomFun{coerce} functions: one from \axiomType{FortranCode} and one from \axiomType{List FortranCode}. There is also a \axiomFun{coerce} from \axiomType{Record( localSymbols: SymbolTable, code: List FortranCode)} which is used for passing extra symbol information about the ASP.

So for example, to integrate the function abs(x) we could use the built-in \axiomFun{abs} function. But suppose we want to get back to basics and define it directly, then we could do the following:

\spadpaste{d01ajf(-1.0, 1.0, 0.0, 1.0e-5, 800, 200, -1, cond(LT(X,0), assign(F,-X), assign(F,X))) result }

The \axiomFunFrom{cond}{FortranCode} operation creates a conditional clause and the \axiomFunFrom{assign}{FortranCode} an assignment statement.

Suppose we have created the file ``asp.f'' as follows:

\begin{verbatim}
DOUBLE PRECISION FUNCTION F(X)
    DOUBLE PRECISION X
    F=4.0D0/(X*X+1.0D0)
    RETURN
END
\end{verbatim}

and wish to pass it to the NAG routine \axiomFun{d01ajf} which performs one-dimensional quadrature. We can do this as follows:

\begin{verbatim}
d01ajf(0.0 ,1.0, 0.0, 1.0e-5, 800, 200, -1, "asp.f")
\end{verbatim}
\indentrel{3}\begin{verbatim}
\end{verbatim}
\indentrel{-3}\end{patch}

\indentrel{3}\begin{verbatim}
(2) 1.0
Type: DoubleFloat
\end{verbatim}
General Fortran-generation utilities in Axiom

--- ug15.ht ---

This section describes more advanced facilities which are available to users who wish to generate Fortran code from within Axiom. There are facilities to manipulate templates, store type information, and generate code fragments or complete programs.

A template is a skeletal program which is 'fleshed out' with data when it is processed. It is a sequence of active and passive parts: active parts are sequences of Axiom commands which are processed as if they had been typed into the interpreter; passive parts are simply echoed verbatim on the Fortran output stream.

Suppose, for example, that we have the following template, stored in the file `test.tem':

```fortran
-- A simple template
beginVerbatim
  DOUBLE PRECISION FUNCTION F(X)
  DOUBLE PRECISION X
endVerbatim
outputAsFortran("F",f)
beginVerbatim
  RETURN
  END
endVerbatim
```

The passive parts lie between the two tokens `beginVerbatim' and `endVerbatim'. There are two active
statements: one which is simply an Axiom (\texttt{---\{\verb+--+\}---}) comment, and one which produces an assignment to the current value of \texttt{f}. We could use it as follows:
\begin{verbatim}
(4) ->f := 4.0/(1+X**2)
4
(4) -----
2
X + 1
\end{verbatim}

\begin{verbatim}
(5) ->processTemplate "test.tem"
DOUBLE PRECISION FUNCTION F(X)
DOUBLE PRECISION X
F=4.0D0/(X*X+1.0D0)
RETURN
END

(5) "CONSOLE"
\end{verbatim}

(A more reliable method of specifying the filename will be introduced below.) Note that the Fortran assignment \texttt{F=4.0D0/(X*X+1.0D0)} automatically converted 4.0 and 1 into DOUBLE PRECISION numbers; in general, the Axiom Fortran generation facility will convert anything which should be a floating point object into either a Fortran REAL or DOUBLE PRECISION object.

Which alternative is used is determined by the command
\begin{verbatim}
)spadpaste)set fortran precision
\end{verbatim}

It is sometimes useful to end a template before the file itself ends (e.g. to allow the template to be tested incrementally or so that a piece of text describing how the template works can be included). It is of course possible to "comment-out" the remainder of the file. Alternatively, the single token \texttt{endInput} as part of an active portion of the template will cause processing to be ended prematurely at that point.

The \axiomFun{processTemplate} command comes in two flavours. In the first case, illustrated above, it takes one argument of domain \axiomType{FileName}, the name of the template to be processed, and writes its output on the current Fortran output stream. In general, a filename can be generated from \texttt{directory}, \texttt{name} and \texttt{extension} components, using the operation \axiomFun{filename}, as in
\begin{verbatim}
processTemplate filename("","test","tem")
\end{verbatim}
There is an alternative version of \axiomFun{processTemplate}, which
takes two arguments (both of domain \axiomType{FileName}). In this
case the first argument is the name of the template to be processed,
and the second is the file in which to write the results. Both
versions return the location of the generated Fortran code as their
result (\tt "CONSOLE" in the above example).

It is sometimes useful to be able to mix active and passive parts of a
line or statement. For example you might want to generate a Fortran
Comment describing your data set. For this kind of application we
provide three functions as follows:
\begin{tabular}{p{1.8in}p{2.6in}}
\axiomFun{fortranLiteral} & writes a string on the Fortran output
stream \\\n\axiomFun{fortranCarriageReturn} & writes a carriage return on the
Fortran output stream \\\n\axiomFun{fortranLiteralLine} & writes a string followed by a return
on the Fortran output stream
\end{tabular}

So we could create our comment as follows:
\begin{spad}
\m := matrix [[1,2,3],[4,5,6]]
\end{spad}
We should stress that these functions, together with the \axiomFun{outputAsFortran} function are the \emph{only} sure ways of getting output to appear on the Fortran output stream. Attempts to use Axiom commands such as \axiomFun{output} or \axiomFun{writeline} may appear to give the required result when displayed on the console, but will give the wrong result when Fortran and algebraic output are sent to differing locations. On the other hand, these functions can be used to send helpful messages to the user, without interfering with the generated Fortran.

\subsubsection{Manipulating the Fortran Output Stream}
\begin{tabular}{ll}
\axiomFun{clearFortranOutputStack} & resets the stack to the console \\
\end{tabular}

Sometimes it is useful to manipulate the Fortran output stream in a program, possibly without being aware of its current value. The main use of this is for gathering type declarations (see `Fortran Types` below) but it can be useful in other contexts as well. Thus we provide a set of commands to manipulate a stack of (open) output streams. Only one stream can be written to at any given time. The stack is never empty---its initial value is the console or the current value of the Fortran output stream, and can be determined using 
\begin{verbatim}
\spadpaste{topFortranOutputStack()}
\end{verbatim}
(see below).

The commands available to manipulate the stack are: 
\begin{verbatim}
\axiomFun{clearFortranOutputStack} & resets the stack to the console \\
\end{verbatim}
<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\axiomFun{pushFortranOutputStack}</td>
<td>pushes a \axiomType{FileName} onto the stack</td>
</tr>
<tr>
<td>\axiomFun{popFortranOutputStack}</td>
<td>pops the stack</td>
</tr>
<tr>
<td>\axiomFun{showFortranOutputStack}</td>
<td>returns the current stack</td>
</tr>
<tr>
<td>\axiomFun{topFortranOutputStack}</td>
<td>returns the top element of the stack</td>
</tr>
</tbody>
</table>

These commands are all part of \axiomType{FortranOutputStackPackage}.

### Fortran Types

When generating code it is important to keep track of the Fortran types of the objects which we are generating. This is useful for a number of reasons, not least to ensure that we are actually generating legal Fortran code. The current type system is built up in several layers, and we shall describe each in turn.

#### FortranScalarType

This domain represents the simple Fortran datatypes: REAL, DOUBLE PRECISION, COMPLEX, LOGICAL, INTEGER, and CHARACTER. It is possible to \axiomFun{coerce} a \axiomType{String} or \axiomType{Symbol} into the domain, test whether two objects are equal, and also apply the predicate functions \axiomFun{real?}, \axiomFun{complex?}, \axiomFun{logical?}, \axiomFun{integer?}, \axiomFun{character?} etc.

#### FortranType

This domain represents "full" types: i.e., datatype plus array dimensions (where appropriate) plus whether or not the parameter is an external subprogram. It is possible to \axiomFun{coerce} an object of \axiomType{FortranScalarType} into the domain or \axiomFun{construct} one from an element of \axiomType{FortranScalarType}, a list of \axiomType{Polynomial Integer}s (which can of course be simple
integers or symbols) representing its dimensions, and a
\texttt{Boolean} declaring whether it is external or not. The list
of dimensions must be empty if the \texttt{Boolean} is \texttt{true}.
The functions \texttt{scalarTypeOf}, \texttt{dimensionsOf} and
\texttt{external?} return the appropriate parts, and it is possible
to get the various basic Fortran Types via functions like
\texttt{fortranReal}.
\protect\xtc{For example:}
\begin{verbatim}
{type:=construct(real,[i,10],false)$FortranType}
\end{verbatim}
\protect\xtc{or}
\begin{verbatim}
{type:=[real,[i,10],false]$FortranType\bound{type}}
\end{verbatim}
\protect\xtc{}\begin{verbatim}
{scalarTypeOf type\free{type}}
\end{verbatim}
\protect\xtc{}\begin{verbatim}
{dimensionsOf type\free{type}}
\end{verbatim}
\protect\xtc{}\begin{verbatim}
{external? type\free{type}}
\end{verbatim}
\ protect\xtc{}\begin{verbatim}
{fortranLogical()}
\end{verbatim}
\protect\xtc{}\begin{verbatim}
{construct(integer,[],true)$FortranType}
\end{verbatim}
\protect\xtc{}\begin{verbatim}
{empty} & creates a new \texttt{SymbolTable} \protect\begin{tabular}{ll}
\texttt{declare} & creates a new \texttt{SymbolTable} \\ & \texttt{empty} & creates a new \texttt{SymbolTable} \\ & \texttt{declare} & creates a new entry in a table \\ & \end{tabular}{
\textbf{axiomFun\{fortranTypeOf\}} & returns the type of an object in a table \& \\ & \textbf{axiomFun\{parametersOf\}} & returns a list of all the symbols in the table \& \\ & \textbf{axiomFun\{typeList\}} & returns a list of all objects of a given type \& \\ & \textbf{axiomFun\{typeLists\}} & returns a list of lists of all objects sorted by type \& \\ & \textbf{axiomFun\{externalList\}} & returns a list of all \texttt{EXTERNAL} objects \& \\ & \textbf{axiomFun\{printTypes\}} & produces Fortran type declarations from a table\& \\
end{tabular}

\begin{tabular}{|l|}
\hline
\textbf{empty} & \tab{25}creates a new \texttt{SymbolTable}\\
\textbf{declare!} & \tab{25}creates a new entry in a table \\
\textbf{fortranTypeOf} & \tab{25}returns the type of an object in a table \\
\textbf{parametersOf} & \tab{25}returns a list of all the symbols in the table \\
\textbf{typeList} & \tab{25}returns a list of all objects of a given type \\
\textbf{typeLists} & \tab{25}returns a list of lists of all objects sorted by type \\
\textbf{externalList} & \tab{25}returns a list of all \texttt{EXTERNAL} objects \\
\textbf{printTypes} & \tab{25}produces Fortran type declarations from a table\\
\hline
\end{tabular}

\begin{verbatim}
\axiomFun{empty} returns a new \texttt{SymbolTable} creation
\axiomFunX{declare} creates a new entry in a table
\axiomFun{fortranTypeOf} returns the type of an object in a table
\axiomFun{parametersOf} returns a list of all the symbols in the table
\axiomFun{typeList} returns a list of all objects of a given type
\axiomFun{typeLists} returns a list of lists of all objects sorted by type
\axiomFun{externalList} returns a list of all \texttt{EXTERNAL} objects
\axiomFun{printTypes} produces Fortran type declarations from a table
\end{verbatim}
This domain creates and manipulates one global symbol table to be used, for example, during template processing. It is also used when linking to external Fortran routines. The information stored for each subprogram (and the main program segment, where relevant) is:

- its name;
- its return type;
- its argument list;
- and its argument types.

Initially, any information provided is deemed to be for the main program segment.

Issuing the following command indicates that from now on all information refers to the subprogram `F`.

```
\spadpaste{newSubProgram F}
```

It is possible to return to processing the main program segment by issuing the command:

```
\spadpaste{endSubProgram()}
```

The following commands exist:

```
\begin{tabular}{p{1.6in}p{2.8in}}
axiomFunX{returnType}& declares the return type of the current subprogram \\
& \\
\end{tabular}
```
In addition there are versions of these commands which are parameterised by the name of a subprogram, and others parameterised by both the name of a subprogram and by an instance of \axiomType{TheSymbolTable}. 

\spadpaste{newSubProgram F \bound{forPleasure}}

\spadpaste{argumentList!(F,[X])\free{forPleasure}}

This section describes facilities for representing Fortran statements, and building up complete subprograms from them.

This domain is used to represent statements like \( x < y \). Although these can be represented directly in Axiom, it is a little cumbersome, since Axiom evaluates the last statement, for example, to \( \text{true} \) (since \( x \) is lexicographically less than \( y \)).

Instead we have a set of operations, such as \( \text{axiomFun(LT)} \) to represent \( x < y \), to let us build such statements. The available constructors are:

\[
\begin{align*}
\text{axiomFun(LT)} & \quad < \\
\text{axiomFun(GT)} & \quad > \\
\text{axiomFun(LE)} & \quad \leq \\
\text{axiomFun(GE)} & \quad \geq \\
\text{axiomFun(EQ)} & \quad = \\
\text{axiomFun(AND)} & \quad \text{and} \\
\text{axiomFun(OR)} & \quad \text{or} \\
\text{axiomFun(NOT)} & \quad \text{not}
\end{align*}
\]
So for example:

\begin{verbatim}
LT(x,y)
\end{verbatim}

\subsubsection{FortranCode}

This domain represents code segments or operations: currently assignments, conditionals, blocks, comments, gotos, continues, various kinds of loops, and return statements.

For example we can create quite a complicated conditional statement using assignments, and then turn it into Fortran code:

\begin{verbatim}
c := cond(LT(X,Y),assign(F,X),cond(GT(Y,Z),assign(F,Y),assign(F,Z)))
\end{verbatim}

The Fortran code is printed on the current Fortran output stream.

\subsubsection{FortranProgram}

This domain is used to construct complete Fortran subprograms out of elements of \texttt{FortranCode}. It is parameterised by the name of the target subprogram (a \texttt{Symbol}), its return type (from \texttt{Union(FortranScalarType,'void')}), its arguments (from \texttt{List Symbol}), and its symbol table (from \texttt{SymbolTable}). One can \texttt{coerce} elements of either \texttt{FortranCode} or \texttt{Expression} into it.

First of all we create a symbol table:

\begin{verbatim}
symbols := empty()$SymbolTable\bound{symbols}
\end{verbatim}

Now put some type declarations into it:

\begin{verbatim}
declare![X,Y],fortranReal(),symbols\free{symbols}
\end{verbatim}

Then (for convenience)
we set up the particular instantiation of \texttt{FortranProgram}:
\begin{verbatim}
FP := FortranProgram(F,real,[X,Y],symbols)\free{symbols}
\bound{FP}
\end{verbatim}

Create an object of type \texttt{Expression(Integer)}:
\begin{verbatim}
asp := X*sin(Y)\bound{asp}
\end{verbatim}

Now \texttt{coerce} it into \texttt{FP}, and print its Fortran form:
\begin{verbatim}
outputAsFortran(asp::FP)\free{FP asp}
\end{verbatim}

We can generate a \texttt{FortranProgram} using \texttt{FortranCode}. For example:
\begin{verbatim}
Augment our symbol table:
\end{verbatim}
\begin{verbatim}
declare!(Z,fortranReal(),symbols)\free{symbols}\bound{Z}
\end{verbatim}

and transform the conditional expression we prepared earlier:
\begin{verbatim}
outputAsFortran([c,returns()::FP) \free{FP c Z}
\end{verbatim}
\begin{verbatim}
1 2 3

Some technical information

The model adopted for the link is a server-client configuration -- Axiom acting as a client via a local agent (a process called \texttt{nagman}). The server side is implemented by the \texttt{nagd} daemon process which may run on a different host. The \texttt{nagman} local agent is started by default whenever you start Axiom. The \texttt{nagd} server must be started separately. Instructions for installing and running the server are supplied in the NAG documentation. Use the \spadcmd{)set naglink host} system command to point your local agent to a server in your network.

On the Axiom side, one sees a set of \emph{packages} (ask \Browse{} for \emph{Nag*}) for each chapter, each exporting operations with the same name as a routine in the \texttt{naglib}. The arguments and return value of each operation belong to standard Axiom types.

The \texttt{man} pages for the \texttt{naglib} are accessible via the description of each operation in \Browse{} (among other places).

In the implementation of each operation, the set of inputs is passed to the local agent \texttt{nagman}, which makes a Remote Procedure Call (RPC) to the remote \texttt{nagd} daemon process. The local agent receives the RPC results and forwards them to the Axiom workspace where they are interpreted appropriately.

How are Fortran subroutines turned into RPC calls? For each Fortran routine in the \texttt{naglib}, a C main() routine is supplied. Its job is to assemble the RPC input (numeric) data stream into the appropriate Fortran data structures for the routine, call the Fortran routine from C and serialize the results into an RPC output data stream.

Many \texttt{naglib} routines accept ASPs (Argument Subprogram Parameters). These specify user-supplied Fortran routines (e.g. a routine to supply values of a function is required for numerical integration). How are they handled? There are new facilities in Axiom to help. A set of Axiom domains has been provided to turn values in standard Axiom types (such as Expression Integer) into the appropriate piece of Fortran for each case (a filename pointing to Fortran source for the ASP can always be supplied instead). Ask \Browse{} for \emph{Asp*} to see these domains. The Fortran fragments are included in the outgoing RPC stream, but \texttt{nagd} intercepts them, compiles them, and links them with the main() C program before executing...
the resulting program on the numeric part of the RPC stream.

Interactive Front-end and Language

⇒ “notitle” (ugLangLoopsBreakPage) 9 on page 1770
⇒ “notitle” (ugLangBlocksPage) 9 on page 1753

\begin{page}{ugWhatsNewLanguagePage}
{15.4. Interactive Front-end and Language}
\beginscroll

The \axiom{leave} keyword has been replaced by the \axiom{break} keyword for compatibility with the new Axiom extension language. See section \downlink{``break in Loops''}{ugLangLoopsBreakPage} in Section 5.4.3\ignore{ugLangLoopsBreak} for more information.

Curly braces are no longer used to create sets. Instead, use \axiomFun{set} followed by a bracketed expression. For example,

\xtc{
}{
\spadpaste{set \[1,2,3,4\]}
}

Curly braces are now used to enclose a block (see section \downlink{``Blocks''}{ugLangBlocksPage} in Section 5.2\ignore{ugLangBlocks} for more information). For compatibility, a block can still be enclosed by parentheses as well.

New coercions to and from type \axiomType{Expression} have been added. For example, it is now possible to map a polynomial represented as an expression to an appropriate polynomial type.

Various messages have been added or rewritten for clarity.

\endscroll
\autobuttons
\end{page}
Library

⇒ “notitle” (FullPartialFracExpansionXmpPage) 3.46 on page 549

The \axiomType{FullPartialFracExpansion} domain has been added. This domain computes factor-free full partial fraction expansions. See section \downlink{'FullPartialFracExpansion'} for examples.

We have implemented the Bertrand/Cantor algorithm for integrals of hyperelliptic functions. This brings a major speedup for some classes of algebraic integrals.

We have implemented a new (direct) algorithm for integrating trigonometric functions. This brings a speedup and an improvement in the answer quality.

The \{\sf SmallFloat\} domain has been renamed \axiomType{DoubleFloat} and \{\sf SmallInteger\} has been renamed \axiomType{SingleInteger}. The new abbreviations as
We have defined the macro \(\texttt{SmallFloat}\), to expand to \axiomType{DoubleFloat} and modified the documentation and input file examples to use the new names and abbreviations. You should do the same in any private Axiom files you have.

There are many new categories, domains and packages related to the NAG Library Link facility. See the file

\unixcommand{\texttt{vi} +"/naglink" \env{AXIOM}/.../src/algebra/exposed.lsp}

for a list of constructors in the \texttt{naglink} Axiom exposure group.

We have made improvements to the differential equation solvers and there is a new facility for solving systems of first-order linear differential equations. In particular, an important fix was made to the solver for inhomogeneous linear ordinary differential equations that corrected the calculation of particular solutions. We also made improvements to the polynomial and transcendental equation solvers including the ability to solve some classes of systems of transcendental equations.

The efficiency of power series have been improved and left and right expansions of \spad{\tan(f(x))} at \spad{x =} a pole of \spad{f(x)} can now be computed. A number of power series bugs were fixed and the \axiomType{GeneralUnivariatePowerSeries} domain was added. The power series variable can appear in the coefficients and when this happens, you cannot differentiate or integrate the series. Differentiation and integration with respect to other variables is supported.

A domain was added for representing asymptotic expansions of a function at an exponential singularity.

For limits, the main new feature is the exponential expansion domain used to treat certain exponential singularities. Previously, such singularities were treated in an \texttt{ad hoc} way and only a few cases were covered. Now Axiom can do things like

\begin{verbatim}
limit( (x+1)**(x+1)/x**x - x**x/(x-1)**(x-1), x = \%plusInfinity)
\end{verbatim}
in a systematic way. It only does one level of nesting, though. In
other words, we can handle \spad{exp()} some function with a pole
\spad{}), but not \texttt{\linebreak}\spad{exp(exp() some function}
with a pole \spad{}).

The computation of integral bases has been improved through careful
use of Hermite row reduction. A P-adic algorithm for function fields
of algebraic curves in finite characteristic has also been developed.

Miscellaneous: There is improved conversion of definite and indefinite
integrals to \axiomType{InputForm}; binomial coefficients are
displayed in a new way; some new simplifications of radicals have been
implemented; the operation \spadfun{complexForm} for converting to
rectangular coordinates has been added; symmetric product operations
have been added to \axiomType{LinearOrdinaryDifferentialOperator}.

CHAPTER 19. USERS GUIDE CHAPTER 16

Introduction

System commands are used to perform Axiom environment management. Among the commands are those that display what has been defined or computed, set up multiple logical Axiom environments (frames), clear definitions, read files of expressions and commands, show what functions are available, and terminate Axiom.

Some commands are restricted: the commands

\begin{verbatim}
)set userlevel interpreter
)set userlevel compiler
)set userlevel development
\end{verbatim}

set the user-access level to the three possible choices. All commands are available at \texttt{development} level and the fewest are available at \texttt{interpreter} level. The default user-level is \texttt{interpreter}. In addition to the \spadcmd{)set} command (discussed in Section B.21) you can use the Hyperdoc settings facility to change the \texttt{user-level}. \texht{}{Click on \lispmemolink{Settings}{(|htSystemVariables|)} here to immediately go to the settings facility.}

Each command listing begins with one or more syntax pattern descriptions plus examples of related commands. The syntax descriptions are intended to be easy to read and do not necessarily represent the most compact way of specifying all possible arguments and options; the descriptions may occasionally be redundant.

All system commands begin with a right parenthesis which should be in the first available column of the input line (that is, immediately
after the input prompt, if any). System commands may be issued
directly to Axiom or be included in {bf .input} files.

A system command {it argument} is a word that directly follows the
command name and is not followed or preceded by a right parenthesis.
A system command {it option} follows the system command and is
directly preceded by a right parenthesis. Options may have arguments:
they directly follow the option. This example may make it easier to
remember what is an option and what is an argument:

\centerline{{\tt )syscmd {it arg1 arg2} )opt1
{it opt1arg1 opt1arg2} )opt2 {it opt2arg1} ...}}

In the system command descriptions, optional arguments and options are
enclosed in brackets ("lanb'' and "ranb''). If an argument or
option name is in italics, it is meant to be a variable and must have
some actual value substituted for it when the system command call is
made. For example, the syntax pattern description

\noindent
{tt }read {it fileName} {tt \lanb}quietly\ranb{}

would imply that you must provide an actual file name for
{it fileName} but need not use the {tt quietly} option.
Thus
\begin{verbatim}
)read matrix.input
\end{verbatim}
is a valid instance of the above pattern.

System command names and options may be abbreviated and may be in
upper or lower case.
The case of actual arguments may be significant, depending on the
particular situation (such as in file names).
System command names and options may be abbreviated to the minimum
number of starting letters so that the name or option is unique.
Thus
\begin{verbatim}
)s Integer
\end{verbatim}
is not a valid abbreviation for the {tt set} command,
because both {tt set} and {tt show}
begin with the letter "s".

Typically, two or three letters are sufficient for disambiguating names.
In our descriptions of the commands, we have used no abbreviations for
either command names or options.

In some syntax descriptions we use a vertical line "\vertline" to
indicate that you must specify one of the listed choices. For
example, in \begin{verbatim}
\end{verbatim} only \{tt on\} and \{tt off\} are acceptable words for following \{tt boot\}. We also sometimes use ‘‘...’’ to indicate that additional arguments or options of the listed form are allowed. Finally, in the syntax descriptions we may also list the syntax of related commands.

\par
\noindent{\bf Command Description:}
This command is used to query, set and remove abbreviations for category, domain and package constructors.
Every constructor must have a unique abbreviation.
This abbreviation is part of the name of the subdirectory under which the components of the compiled constructor are stored.
Furthermore, by issuing this command you let the system know what file to load automatically if you use a new constructor.
Abbreviations must start with a letter and then be followed by
up to seven letters or digits. Any letters appearing in the abbreviation must be in uppercase.

When used with the \tt{query} argument, this command may be used to list the name associated with a particular abbreviation or the abbreviation for a constructor. If no abbreviation or name is given, the names and corresponding abbreviations for {\it all} constructors are listed.

The following shows the abbreviation for the constructor \spadtype{List}:

\begin{verbatim}
)abbreviation query List
\end{verbatim}

The following shows the constructor name corresponding to the abbreviation \spadtype{NNI}:

\begin{verbatim}
)abbreviation query NNI
\end{verbatim}

The following lists all constructor names and their abbreviations.

\begin{verbatim}
)abbreviation query
\end{verbatim}

To add an abbreviation for a constructor, use this command with \tt{category}, \tt{domain} or \tt{package}.

The following add abbreviations to the system for a category, domain and package, respectively:

\begin{verbatim}
)abbreviation domain SET Set
)abbreviation category COMPCAT ComplexCategory
)abbreviation package LIST2MAP ListToMap
\end{verbatim}

If the \tt{quiet} option is used, no output is displayed from this command. You would normally only define an abbreviation in a library source file. If this command is issued for a constructor that has already been loaded, the constructor will be reloaded next time it is referenced. In particular, you can use this command to force the automatic reloading of constructors.

To remove an abbreviation, the \tt{remove} argument is used. This is usually only used to correct a previous command that set an abbreviation for a constructor name. If, in fact, the abbreviation does exist, you are prompted for confirmation of the removal request.

Either of the following commands will remove the abbreviation \spadtype{VECTOR2} and the constructor name \spadtype{VectorFunctions2} from the system:

\begin{verbatim}
\end{verbatim}
\begin{verbatim}
)boot times3(x) == 3*x
\end{verbatim}
creates and compiles the \Lisp{} function \texttt{times3} obtained by translating the BOOT code.

\downlink{``)lisp''}{ugSysCmdlispPage} in section B.15
\begin{page}{ugSysCmdcdPage}{B.4. \texttt{)cd}}

\beginscroll

\par\noindent{\bf User Level Required:} interpreter
\par\noindent{\bf Command Syntax:}
\begin{itemize}
\item \texttt{)cd} \texttt{directory}
\end{itemize}
\par\noindent{\bf Command Description:}
This command sets the Axiom working current directory. The current directory is used for looking for input files (for \texttt{)read}), Axiom library source files (for \texttt{)compile}), saved history environment files (for \texttt{)history)restore}), compiled Axiom library files (for \texttt{spadvcmd}{}library}), and files to edit (for \texttt{)edit}). It is also used for writing spool files (via \texttt{)spool}), writing history input files (via \texttt{)history)write}) and history environment files (via \texttt{)history)save}), and compiled Axiom library files (via \texttt{)compile}).

If issued with no argument, this command sets the Axiom
current directory to your home directory. If an argument is used, it must be a valid directory name. Except for the ‘‘\tt cd’’ at the beginning of the command, this has the same syntax as the operating system ‘‘\tt cd’’ command.

Also See:
- `compile'` in section B.7
- `edit'` in section B.9
- `history'` in section B.13
- `library'` in section B.14
- `read'` in section B.20
- `spool'` in section B.32

This command is used to close down interpreter client processes. Such processes are started by Hyperdoc to run Axiom examples when you click on their text. When you have finished examining or modifying the example and you do not want the extra window around anymore, issue

```
)close
```

to the Axiom prompt in the window.

If you try to close down the last remaining interpreter client
process, Axiom will offer to close down the entire Axiom session and return you to the operating system by displaying something like
\begin{verbatim}
This is the last Axiom session. Do you want to kill Axiom?
\end{verbatim}
Type "y" (followed by the Return key) if this is what you had in mind. Type "n" (followed by the Return key) to cancel the command.

You can use the \tt{quietly} option to force Axiom to close down the interpreter client process without closing down the entire Axiom session.

\par\noindent{bf Command Syntax:}
\begin{items}
\item{\tt )clear all}
\item{\tt )clear completely}
\item{\tt )clear properties all}
\item{\tt )clear properties} \{\it obj1 \lanb{}obj2 ...\ranb{}}
\item{\tt )clear value all}
\item{\tt )clear value} \{\it obj1 \lanb{}obj2 ...\ranb{}}
\item{\tt )clear mode all}
\item{\tt )clear mode} \{\it obj1 \lanb{}obj2 ...\ranb{}}
\end{items}
\end{scroll}
This command is used to remove function and variable declarations, definitions and values from the workspace. To empty the entire workspace and reset the step counter to 1, issue
\begin{verbatim}
)clear all
\end{verbatim}
To remove everything in the workspace but not reset the step counter, issue
\begin{verbatim}
)clear properties all
\end{verbatim}
To remove everything about the object \texttt{x}, issue
\begin{verbatim}
)clear properties x
\end{verbatim}
To remove everything about the objects \texttt{x, y} and \texttt{f}, issue
\begin{verbatim}
)clear properties x y f
\end{verbatim}
The word \texttt{properties} may be abbreviated to the single letter \texttt{p}.
\begin{verbatim}
)clear p all
)clear p x
)clear p x y f
\end{verbatim}
All definitions of functions and values of variables may be removed by either
\begin{verbatim}
)clear value all
)clear v all
\end{verbatim}
This retains whatever declarations the objects had. To remove definitions and values for the specific objects \texttt{x, y} and \texttt{f}, issue
\begin{verbatim}
)clear value x y f
)clear v x y f
\end{verbatim}
To remove the declarations of everything while leaving the definitions and values, issue
\begin{verbatim}
)clear mode all
)clear m all
\end{verbatim}
To remove declarations for the specific objects \texttt{x, y} and
The \texttt{)display names} and \texttt{)display properties} commands may be used to see what is currently in the workspace.

The command
\begin{verbatim}
)clear completely
\end{verbatim}
does everything that \texttt{)clear all} does, and also clears the internal system function and constructor caches.

\endscroll
\autobuttons
\end{page}
You use this command to invoke the Axiom library compiler. This compiles files with file extension `.spad` with the Axiom system compiler. The command first looks in the standard system directories for files with extension `.spad`.

Should you not want the `.library` command automatically invoked, call `.compile` with the `.nolibrary` option. For example,
```
)compile mycode )nolibrary
```
By default, the `.library` system command exposes all domains and categories it processes. This means that the Axiom interpreter will consider those domains and categories when it is trying to resolve a reference to a function.

Sometimes domains and categories should not be exposed. For example, a domain may just be used privately by another domain and may not be meant for top-level use. The `.library` command should still be used, though, so that the code will be loaded on demand. In this case, you should use the `.nolibrary` option on `.compile` and the `.noexpose` option in the `.library` command. For example,
```
)compile mycode.spad )nolibrary
)library mycode )noexpose
```
Once you have established your own collection of compiled code, you may find it handy to use the `.dir` option on the `.library` command. This causes `.library` to process all compiled code in the specified directory. For example,
```
)library )dir /u/jones/quantum
```
You must give an explicit directory after `.dir`, even if you want all compiled code in the current working directory processed.
You can compile category, domain, and package constructors contained in files with file extension `.spad`. You can compile individual constructors or every constructor in a file.

The full filename is remembered between invocations of this command and `)edit` commands. The sequence of commands

```
)compile matrix.spad
)edit
)compile
```

will call the compiler, edit, and then call the compiler again on the file `matrix.spad`. If you do not specify a directory, the working current directory (see description of command `)cd`) is searched for the file. If the file is not found, the standard system directories are searched.

If you do not give any options, all constructors within a file are compiled. Each constructor should have an `)abbreviation` command in the file in which it is defined. We suggest that you place the `)abbreviation` commands at the top of the file in the order in which the constructors are defined. The list of commands serves as a table of contents for the file.

The `)library` option causes directories containing the compiled code for each constructor to be created in the working current directory. The name of such a directory consists of the constructor abbreviation and the `.nrlib` file extension. For example, the directory containing the compiled code for the `MATRIX` constructor is called `MATRIX.nrlib`. The `)nolibrary` option says that such files should not be created.

The `)vartrace` option causes the compiler to generate extra code for the constructor to support conditional tracing of variable assignments. Without this option, this code is suppressed and one cannot use the `)vars` option for the trace command.

The `)constructor` option is used to specify a particular constructor to compile. All other constructors in the file are ignored. The constructor name or abbreviation follows `)constructor`. Thus either

```
)compile matrix.spad )constructor RectangularMatrix
```

or

```
)compile matrix.spad )constructor RMATRIX
```

compiles the `RectangularMatrix` constructor defined in `matrix.spad`.

The `)break` and `)nobreak` options determine what the compiler does when it encounters an error. `)break` is the default and it indicates that
processing should stop at the first error. The value of the \{\texttt{set break}\} variable then controls what happens.

\item \texttt{)display value} \{\texttt{\lanb{}obj1 \lanb{}obj2 ...}\texttt{\ranb}\texttt{\ranb}\texttt{\ranb}\}
\item \texttt{)display mode all}
\item \texttt{)display mode} \{\texttt{\lanb{}obj1 \lanb{}obj2 ...}\texttt{\ranb}\texttt{\ranb}\texttt{\ranb}\}
\item \texttt{)display names}
\item \texttt{)display operations} \{\texttt{\lanb{}opName}\}
\end{itemize}

This command is used to display the contents of the workspace and
signatures of functions with a given name.  \footnote{A \spadgloss{signature} gives the argument and return types of a function.}

The command
\begin{verbatim}
)display names
\end{verbatim}
lists the names of all user-defined objects in the workspace.  This is useful if you do not wish to see everything about the objects and need only be reminded of their names.

The commands
\begin{verbatim}
)display(verbatim
)display all
)display properties
)display properties all
\end{verbatim}
all do the same thing: show the values and types and declared modes of all variables in the workspace.  If you have defined functions, their signatures and definitions will also be displayed.

To show all information about a particular variable or user functions, for example, something named \ttit{d}, issue
\begin{verbatim}
)display(properties d
\end{verbatim}
To just show the value (and the type) of \ttit{d}, issue
\begin{verbatim}
)display(value d
\end{verbatim}
To just show the declared mode of \ttit{d}, issue
\begin{verbatim}
)display(mode d
\end{verbatim}

All modemaps for a given operation may be displayed by using \ttit{display operations}.  A \spadgloss{modemap} is a collection of information about a particular reference to an operation.  This includes the types of the arguments and the return value, the location of the implementation and any conditions on the types.  The modemap may contain patterns.  The following displays the modemaps for the operation \spadfunFrom{complex}{ComplexCategory}:
\begin{verbatim}
)display d op complex
\end{verbatim}

\par
\noindent{\bf Command Syntax:}
\begin{items}
\item{\tt )edit} \lanb{}{\it filename}\ranb{}
\end{items}
\par
\noindent{\bf Command Description:}

This command is used to edit files. It works in conjunction with the {\tt )read} and {\tt )compile} commands to remember the name of the file on which you are working. By specifying the name fully, you can edit any file you wish. Thus
\begin{verbatim}
)edit /u/julius/matrix.input
\end{verbatim}
will place you in an editor looking at the file {\tt /u/julius/matrix.input}. By default, the editor is {\tt vi}, but if you have an EDITOR shell environment variable defined, that editor will be used. When Axiom is running under the X Window System, it will try to open a separate {\tt xterm} running your editor if it thinks one is necessary.
For example, under the Korn shell, if you issue
\begin{verbatim}
export EDITOR=emacs
\end{verbatim}
then the emacs editor will be used by \spadcmd{)edit}.

If you do not specify a file name, the last file you edited, read or compiled will be used.
If there is no ‘‘last file’’ you will be placed in the editor editing an empty unnamed file.

It is possible to use the \tt{system} command to edit a file directly.
For example,
\begin{verbatim}
)system emacs /etc/rc.tcpip
\end{verbatim}
calls \tt{emacs} to edit the file.

\begin{page}{ugSysCmdframePage}{B.11. )frame}
\beginscroll

User Level Required: interpreter

Command Syntax:

\begin{items}
  \item \verb|)frame new \{\it frameName}\}
  \item \verb|)frame drop \{\it frameName\}\}
  \item \verb|)frame next\}
  \item \verb|)frame last\}
  \item \verb|)frame names\}
  \item \verb|)frame import \{\it frameName\}\}
    \{\it \lanb{}objectName1 \lanb{}objectName2 \ldots \lanb{}\ranb{}\}
  \item \verb|)set message frame on \midline{} off\}
  \item \verb|)set message prompt frame\}
\end{items}

Command Description:

A \{\it frame\} can be thought of as a logical session within the physical session that you get when you start the system. You can have as many frames as you want, within the limits of your computer’s
storage, paging space, and so on. Each frame has its own \{it step number\}, \{it environment\} and \{it history\}. You can have a variable named \{tt a\} in one frame and it will have nothing to do with anything that might be called \{tt a\} in any other frame.

Some frames are created by the Hyperdoc program and these can have pretty strange names, since they are generated automatically. To find out the names of all frames, issue
\begin{verbatim}
)frame names
\end{verbatim}
It will indicate the name of the current frame.

You create a new frame \{bf quark\} by issuing
\begin{verbatim}
)frame new quark
\end{verbatim}

The history facility can be turned on by issuing either \{tt set history on\} or \{tt history )on\}. If the history facility is on and you are saving history information in a file rather than in the Axiom environment then a history file with filename \{bf quark.axh\} will be created as you enter commands.

If you wish to go back to what you were doing in the \{bf initial\} frame, use
\begin{verbatim}
)frame next
\end{verbatim}
or
\begin{verbatim}
)frame last
\end{verbatim}
to cycle through the ring of available frames to get back to \{bf initial\}.

If you want to throw away a frame (say \{bf quark\}), issue
\begin{verbatim}
)frame drop quark
\end{verbatim}

If you omit the name, the current frame is dropped.

If you do use frames with the history facility on and writing to a file, you may want to delete some of the older history files. These are directories, so you may want to issue a command like \{tt rm -r quark.axh\} to the operating system.
You can bring things from another frame by using \texttt{frame import}. For example, to bring the \texttt{f} and \texttt{g} from the frame \texttt{"\textbf{quark}"} to the current frame, issue
\begin{verbatim}
)frame import quark f g
\end{verbatim}
If you want everything from the frame \texttt{"\textbf{quark}"}, issue
\begin{verbatim}
)frame import quark
\end{verbatim}
You will be asked to verify that you really want everything.

There are two \texttt{set} flags to make it easier to tell where you are.
\begin{verbatim}
)set message frame on | off
\end{verbatim}
will print more messages about frames when it is set on. By default, it is off.
\begin{verbatim}
)set message prompt frame
\end{verbatim}
will give a prompt that looks like
\begin{verbatim}
initial (1) ->
\end{verbatim}
when you start up. In this case, the frame name and step make up the prompt.

\Rightarrow "notitle" (ugSysCmdreadPage) 19 on page 2570
\Rightarrow "notitle" (ugSysCmdsetPage) 19 on page 2571
User Level Required: interpreter

Command Syntax:

- `)`history `)`on`
- `)`history `)`off`
- `)`history `)`write `{it historyInputFileName}`
- `)`history `)`show \lanb{}{\it n}\ranb{} \lanb{}both\ranb{}`
- `)`history `)`save {it savedHistoryName}
- `)`history `)`restore \lanb{}{\it savedHistoryName}\ranb{}`
- `)`history `)`reset`
- `)`history `)`change {\it n}`
- `)`history `)`memory`
- `)`history `)`file`
- `)`history `)`%`
- `)`history `)`\%{\it n}`
- `)`set history on \vertline{} off`

Command Description:

The `{it history}` facility within Axiom allows you to restore your environment to that of another session and recall previous computational results. Additional commands allow you to review previous input lines and to create an `{bf .input}` file of the lines typed to Axiom.

Axiom saves your input and output if the history facility is turned on (which is the default). This information is saved if either of

\begin{verbatim}
>begin{verbatim}
>set history on
>history >on
>end{verbatim}
\end{verbatim}

has been issued. Issuing either

\begin{verbatim}
>begin{verbatim}
>set history off
>history >off
>end{verbatim}
\end{verbatim}

will discontinue the recording of information.
Whether the facility is disabled or not, the value of `\spadSyntax{\%}` in Axiom always refers to the result of the last computation. If you have not yet entered anything, `\spadSyntax{\%}` evaluates to an object of type `\spadtype{Variable('\%)}`. The function `\spadSyntax{\%\%}` may be used to refer to other previous results if the history facility is enabled. In that case, `{\tt \%\%(n)}` is the output from step `{\tt n}` if `{\tt n > 0}`. If `{\tt n < 0}`, the step is computed relative to the current step. Thus `{\tt \%\%(-1)}` is also the previous step, `{\tt \%\%(-2)}`, is the step before that, and so on. If an invalid step number is given, Axiom will signal an error.

The \emph{environment} information can either be saved in a file or entirely in memory (the default). Each frame ([downlink{'')frame''}{ugSysCmdframePage} in Section B.11\ignore{ugSysCmdframe}) has its own history database. When it is kept in a file, some of it may also be kept in memory for efficiency. When the information is saved in a file, the name of the file is of the form `{\bf FRAME.axh}` where `{\bf FRAME}` is the name of the current frame. The history file is placed in the current working directory ([downlink{''}cd''}{ugSysCmdcdPage} in Section B.4\ignore{ugSysCmdcd}). Note that these history database files are not text files (in fact, they are directories themselves), and so are not in human-readable format.

The options to the `{\tt history}` command are as follows:

\begin{itemize}
\item `{\tt change \ n}` will set the number of steps that are saved in memory to `{\it n}`. This option only has effect when the history data is maintained in a file.
\item If you have issued `{\tt history memory}` (or not changed the default) there is no need to use `{\tt history change}`.
\item `{\tt on}` will start the recording of information.
\item If the workspace is not empty, you will be asked to confirm this request.
\item If you do so, the workspace will be cleared and history data will begin being saved.
\item You can also turn the facility on by issuing `{\tt set history on}`.
\item `{\tt off}` will stop the recording of information.
\item The `{\tt history show}` command will not work after issuing this command.
\item Note that this command may be issued to save time, as there is some performance penalty paid for saving the environment data.
\end{itemize}
You can also turn the facility off by issuing \texttt{)set history off}.

\item[\texttt{)file}] indicates that history data should be saved in an external file on disk.

\item[\texttt{)memory}] indicates that all history data should be kept in memory rather than saved in a file.

Note that if you are computing with very large objects it may not be practical to keep this data in memory.

\item[\texttt{)reset}] will flush the internal list of the most recent workspace calculations so that the data structures may be garbage collected by the underlying \texttt{Lisp} system.

Like \texttt{)history change}, this option only has real effect when history data is being saved in a file.

\item[\texttt{)restore} \texttt{savedHistoryName}] completely clears the environment and restores it to a saved session, if possible.

The \texttt{)save} option below allows you to save a session to a file with a given name. If you had issued 
\texttt{)history save jacobi} the command
\texttt{)history restore jacobi} would clear the current workspace and load the contents of the named saved session. If no saved session name is specified, the system looks for a file called \texttt{last.axh}.

\item[\texttt{)save} \texttt{savedHistoryName}] is used to save a snapshot of the environment in a file.

This file is placed in the current working directory (see \texttt{)cd}) in Section B.4).

Use \texttt{)history restore} to restore the environment to the state preserved in the file.

This option also creates an input file containing all the lines of input since you created the workspace frame (for example, by starting your Axiom session) or last did a \texttt{)clear all} or \texttt{)clear completely}.

\item[\texttt{)show} \texttt{n} \texttt{both}] can show previous input lines and output results.

\texttt{)show} will display up to twenty of the last input lines (fewer if you haven’t typed in twenty lines).

\texttt{)show} \texttt{n} will display up to \texttt{n} of the last input lines.

\texttt{)show} \texttt{both} will display up to five of the last input lines and output results.

\texttt{)show} \texttt{n} \texttt{both} will display up to \texttt{n} of the last input lines and output results.
input lines and output results.

\item[\tt write \it historyInputFile]
creates an \bf .input\ file with the input lines typed since the start
of the session/frame or the last \tt clear all\ or \tt clear
completely\).

If \it historyInputFileName\ does not
contain a period (``.'') in the filename,
\bf .input\ is appended to it.

For example,
\tt history write chaos\)
and
\tt history write chaos.input\)
both write the input lines to a file called \bf chaos.input\ in your
current working directory.

If you issued one or more \tt undo\ commands,
\tt history write\)
eliminates all
input lines backtracked over as a result of \tt undo\).
You can edit this file and then use \tt read\ to have Axiom process
the contents.

CHAPTER 19. USERS GUIDE CHAPTER 16 (UG16.HT)

User Level Required: interpreter

Command Syntax:

\begin{item}
\item{\tt )library \{\it libName1 \lanb{}libName2 ...\ranb{}}}
\item{\tt )library \dir \{\it dirName\}}
\item{\tt )library )only \{\it objName1 \lanb{}objlib2 ...\ranb{}}}
\item{\tt )library )noexpose}
\end{item}

Command Description:

This command replaces the {\tt )load} system command that was available in Axiom releases before version 2.0.

The {\tt )library} command makes available to Axiom the compiled objects in the libraries listed.

For example, if you {\tt compile dopler.as} in your home directory, issue {\tt )library dopler} to have Axiom look at the library, determine the category and domain constructors present, update the internal database with various properties of the constructors, and arrange for the constructors to be automatically loaded when needed.

If the {\tt )noexpose} option has not been given, the constructors will be exposed (that is, available) in the current frame.

If you compiled a file with the old system compiler, you will have an {\it nrlib} present, for example, {\it DOPLER.nrlib,} where {\tt DOPLER} is a constructor abbreviation.

The command {\tt )library DOPLER} will then do the analysis and database updates as above.

To tell the system about all libraries in a directory, use {\tt )library \dir dirName} where {\tt dirName} is an explicit directory.

You may specify ‘.’ as the directory, which means the current directory from which you started the system or the one you set via the {\tt )cd} command. The directory name is required.

You may only want to tell the system about particular constructors within a library. In this case, use the {\tt )only} option. The command {\tt )library dopler )only Test1} will only cause the {\tt Test1} constructor to be analyzed, autoloaded, etc..

Finally, each constructor in a library are usually automatically exposed when the {\tt )library} command is used. Use the {\tt )
\noexpose option if you not want them exposed. At a later time you can use \ttset expose add constructor\t to expose any hidden constructors.

\bf Note for Axiom beta testers: At various times this command was called \ttlocal\t and \ttwith\t before the name \ttlibrary\t became the official name.

\bf Also See:\n\link{\ttcd\t}{ugSysCmdcdPage} in section B.4

\beginscroll

\bf User Level Required: development

\bf Command Syntax:

\begin{items}
\item \tt(lisp) \{\it\lanb{lispExpression}\ranb{}\}
\end{items}

\bf Command Description:

This command is used by Axiom system developers to have single expressions evaluated by the \Lisp system on which Axiom is built. The \it lispExpression\ is read by the \Lisp reader and evaluated. If this expression is not complete (unbalanced parentheses, say), the reader will wait until a complete expression is entered.

\end{scroll}
\autobuttons
\end{page}
Since this command is only useful for evaluating single expressions, the \{tt \)fin\} command may be used to drop out of Axiom into \Lisp{}.

---

User Level Required:} interpreter

Command Syntax:

\begin{items}
\item{\tt )quit}
\end{items}
**Command Description:**

This command is used to terminate Axiom and return to the operating system. Other than by redoing all your computations or by using the \tt{)history )restore} command to try to restore your working environment, you cannot return to Axiom in the same state.

\tt{)pquit} differs from the \tt{)quit} in that it always asks for confirmation that you want to terminate Axiom (the ‘‘p’’ is for ‘‘protected’’).

When you enter the \tt{)pquit} command, Axiom responds

\begin{quote}
Please enter \bf{y} or \bf{yes} if you really want to leave the interactive environment and return to the operating system:
\end{quote}

If you respond with \tt{y} or \tt{yes}, you will see the message

\begin{quote}
You are now leaving the Axiom interactive environment. Issue the command \bf{axiom} to the operating system to start a new session.
\end{quote}

and Axiom will terminate and return you to the operating system (or the environment from which you invoked the system).

If you responded with something other than \tt{y} or \tt{yes}, then the message

\begin{quote}
You have chosen to remain in the Axiom interactive environment.
\end{quote}

will be displayed and, indeed, Axiom would still be running.

\par\noindent{\bf Command Syntax:}
\begin{itemize}
\item{\tt )quit}
\item{\tt )set quit protected \vrule unprotected}
\end{itemize}
\end{items}

\par\noindent{\bf Command Description:}

This command is used to terminate Axiom and return to the operating system.
Other than by redoing all your computations or by using the \tt{)history )restore} command to try to restore your working environment, you cannot return to Axiom in the same state.

\tt{)quit} differs from the \tt{)pquit} in that it asks for confirmation only if the command
\begin{verbatim}
)set quit protected
\end{verbatim}
has been issued.
Otherwise, \tt{)quit} will make Axiom terminate and return you to the operating system (or the environment from which you invoked the system).

The default setting is \tt{)set quit protected} so that \tt{)quit} and \tt{)pquit} behave in the same way.
If you do issue
\begin{verbatim}
)set quit unprotected
\end{verbatim}
we suggest that you do not (somehow) assign \tt{)quit} to be
executed when you press, say, a function key.

\)set

⇒ “notitle” (ugSysCmdquitPage) 19 on page 2569

-- ug16.ht --

\begin{page}{ugSysCmdsetPage}{B.21. }set\}
\beginscroll

\par\noindent\bf User Level Required:} interpreter

\par\noindent\bf Command Syntax:\n
\begin{items}
\item {	t \)set}
\item {	t \)set} \{it label1 \lanb{}... labelN\ranb{}}
\item {	t \)set} \{it label1 \lanb{}... labelN\ranb{} newValue\}
\end{items}

\par\noindent\bf Command Description:\n
The \{tt \)set\} command is used to view or set system variables that control what messages are displayed, the type of output desired, the status of the history facility, the way Axiom user functions are cached, and so on.

Since this collection is very large, we will not discuss them here.
Rather, we will show how the facility is used. We urge you to explore the \tt set options to familiarize yourself with how you can modify your Axiom working environment. There is a Hyperdoc version of this same facility available from the main Hyperdoc menu. Click \lispmemolink{here}{(|htSystemVariables|)} to go to it.

The \tt set command is command-driven with a menu display. It is tree-structured. To see all top-level nodes, issue \tt set by itself.

```
)set
```
Variables with values have them displayed near the right margin. Subtrees of selections have ``\tt ...'' displayed in the value field. For example, there are many kinds of messages, so issue \tt set message to see the choices.

```
)set message
```
The current setting for the variable that displays whether computation times are displayed is visible in the menu displayed by the last command. To see more information, issue

```
)set message time
```
This shows that time printing is on now. To turn it off, issue

```
)set message time off
```
As noted above, not all settings have so many qualifiers. For example, to change the \tt quit command to being unprotected (that is, you will not be prompted for verification), you need only issue

```
)set quit unprotected
```
Also See: \bf{``\tt quit''}\lispmemolink{ugSysCmdquitPage}{ugSysCmdquitPage} in section B.19
)show

\begin{page}{ugSysCmdshowPage}{B.22. )show}\begin{scroll}
\par\noindent{\bf User Level Required:} interpreter

\par\noindent{\bf Command Syntax:}
\begin{items}
\item{\tt )show {\it nameOrAbbrev}}
\item{\tt )show {\it nameOrAbbrev} )operations}
\item{\tt )show {\it nameOrAbbrev} )attributes}
\end{items}

\par\noindent{\bf Command Description:}
This command displays information about Axiom domain, package and category {\it constructors}. If no options are given, the {\tt )operations} option is assumed. For example,
\begin{verbatim}
)show POLY
)show POLY )operations
)show Polynomial
)show Polynomial )operations
\end{verbatim}
each display basic information about the \spadtype{Polynomial} domain constructor and then provide a listing of operations. Since \spadtype{Polynomial} requires a \spadtype{Ring} (for example, \spadtype{Integer}) as argument, the above commands all refer to an unspecified ring {\tt R}. In the list of operations, \spadSyntax{\$} means \spadtype{Polynomial(R)}.

The basic information displayed includes the {\it signature} of the constructor (the name and arguments), the constructor {\it abbreviation}, the {\it exposure status} of the constructor, and the name of the {\it library source file} for the constructor.

If operation information about a specific domain is wanted, the full or abbreviated domain name may be used. For example,
\begin{verbatim}
)show POLY INT
)show POLY INT operations
)show Polynomial Integer
)show Polynomial Integer operations
\end{verbatim}

are among the combinations that will display the operations exported by the domain \spadtype{Polynomial(Integer)} (as opposed to the general \spadtype{Polynomial}). Attributes may be listed by using the \tt{attributes} option.

\(\)spool

\begin{verbatim}
)spool
\end{verbatim}

\noindent{\bf User Level Required:} interpreter

\noindent{\bf Command Syntax:}
\begin{itemize}
\item \tt{)spool} \lanb{\it fileName}\ranb{}
\item \tt{)spool}
\end{itemize}

\noindent{\bf Command Description:}
This command is used to save all Axiom input and output into a file, called a spool file. You can only have one spool file active at a time.

To start spool, issue this command with a filename. For example,
To stop spooling, issue \texttt{)}spool\texttt{ with no filename.

If the filename is qualified with a directory, then the output will be placed in that directory. If no directory information is given, the spool file will be placed in the \texttt{current directory.} The current directory is the directory from which you started Axiom or is the directory you specified using the \texttt{)}cd\texttt{ command.

\textbf{Also See:}
\begin{itemize}
\item \texttt{)}cd\texttt{\begin{itemize}
\end{itemize}
\end{itemize}

\begin{page}{ugSysCmdsynonymPage}{B.24. \texttt{)}synonym\texttt{}}
\beginscroll

\textbf{User Level Required:} interpreter

\textbf{Command Syntax:}

\begin{itemize}
\item \texttt{)}synonym\texttt{}
\item \texttt{)}synonym\texttt{ synonym fullCommand}
\item \texttt{)}what\texttt{ synonyms}
\end{itemize}

\textbf{Command Description:}

This command is used to create short synonyms for system command expressions. For example, the following synonyms might simplify commands you often use.

\begin{verbatim}
})synonym save history )save
\end{verbatim}
Once defined, synonyms can be used in place of the longer command expressions. Thus

```verbatim
fortran on
```

is the same as the longer

```verbatim
set fortran output on
```

To list all defined synonyms, issue either of

```verbatim
synonyms
what synonyms
```

To list, say, all synonyms that contain the substring ‘‘{tt ap}’’, issue

```verbatim
what synonyms ap
```

— ug16.ht —
**User Level Required:** interpreter

**Command Syntax:**
\begin{items}
\item{\tt )system \it cmdExpression}
\end{items}

**Command Description:**
This command may be used to issue commands to the operating system while remaining in Axiom. The \{it cmdExpression\} is passed to the operating system for execution.

To get an operating system shell, issue, for example, \spadcmd{{system sh}}.
When you enter the key combination, \fbox{\bf Ctrl}--\fbox{\bf D} (pressing and holding the \fbox{\bf Ctrl} key and then pressing the \fbox{\bf D} key) the shell will terminate and you will return to Axiom. We do not recommend this way of creating a shell because \Lisp{} may field some interrupts instead of the shell. If possible, use a shell running in another window.

If you execute programs that misbehave you may not be able to return to Axiom. If this happens, you may have no other choice than to restart Axiom and restore the environment via \{history \}restore, if possible.

\end{itemize}
\item{\tt )vars}
\item{\tt )vars} {\it var1 \lanb{}... varN \ranb{}}
\item{\tt )within} {\it executingFunction}
\end{items}

\par
\noindent{\bf Command Description:}

This command is used to trace the execution of functions that make up the Axiom system, functions defined by users, and functions from the system library. Almost all options are available for each type of function but exceptions will be noted below.

To list all functions, constructors, domains and packages that are traced, simply issue
\begin{verbatim}
)trace
\end{verbatim}
To untrace everything that is traced, issue
\begin{verbatim}
)trace )off
\end{verbatim}

When a function is traced, the default system action is to display the arguments to the function and the return value when the function is exited.
Note that if a function is left via an action such as a {\tt THROW}, no return value will be displayed.
Also, optimization of tail recursion may decrease the number of times a function is actually invoked and so may cause less trace information to be displayed.
Other information can be displayed or collected when a function is traced and this is controlled by the various options.
Most options will be of interest only to Axiom system developers.
If a domain or package is traced, the default action is to trace all functions exported.

Individual interpreter, lisp or boot functions can be traced by listing their names after {\tt )trace}.
Any options that are present must follow the functions to be traced.
\begin{verbatim}
)trace f
\end{verbatim}
traces the function {\tt f}. To untrace {\tt f}, issue
\begin{verbatim}
)trace f )off
\end{verbatim}
Note that if a function name contains a special character, it will be necessary to escape the character with an underscore

\begin{verbatim}
)trace _/D_,1
\end{verbatim}

To trace all domains or packages that are or will be created from a particular constructor, give the constructor name or abbreviation after \spad{\texttt{trace}}.

\begin{verbatim}
)trace MATRIX
)trace List Integer
\end{verbatim}

The first command traces all domains currently instantiated with \spad{Matrix}. If additional domains are instantiated with this constructor (for example, if you have used \spad{Matrix(Integer)} and \spad{Matrix(Float)}), they will be automatically traced. The second command traces \spad{List(Integer)}. It is possible to trace individual functions in a domain or package. See the \spad{ops} option below.

The following are the general options for the \spad{trace} command.

%!! system command parser doesn't treat general s-expressions correctly, %!! I recommend not documenting )after )before and )cond
\begin{itemize}
\item \spad{\texttt{after}} \spad{S-expression}\]
\item causes the given \texttt{Lisp} \spad{S-expression} to be %executed after exiting the traced function.
\item \spad{\texttt{before}} \spad{S-expression}\]
\item causes the given \texttt{Lisp} \spad{S-expression} to be %executed before entering the traced function.
\item \spad{break after}]
\item causes a \texttt{Lisp} break loop to be entered after %exiting the traced function.
\item \spad{break before}]
\item causes a \texttt{Lisp} break loop to be entered before %entering the traced function.
\item \spad{break}]
\item is the same as \texttt{break before}.\end{itemize}
causes trace information to be shown only if the given \Lisp{} \S-expression evaluates to non-NIL. For example, the following command causes the system function \tt resolveTT to be traced but to have the information displayed only if the value of the variable \tt \$reportBottomUpFlag is non-NIL.

\begin{verbatim}
%)trace resolveTT )cond \_\_\$reportBottomUpFlag
\end{verbatim}

\item[\tt count]
causes the system to keep a count of the number of times the traced function is entered. The total can be displayed with \tt trace stats and cleared with \tt trace stats reset.

\item[\tt count \it n]
causes information about the traced function to be displayed for the first \it n executions. After the \eth \it n execution, the function is untraced.

\item[\tt depth \it n]
causes trace information to be shown for only \it n levels of recursion of the traced function. The command
\begin{verbatim}
)trace fib )depth 10
\end{verbatim}
will cause the display of only 10 levels of trace information for the recursive execution of a user function \userfun{fib}.

\item[\tt math]]
causes the function arguments and return value to be displayed in the Axiom monospace two-dimensional math format.

\item[\tt nonquietly]]
causes the display of additional messages when a function is traced.

\item[\tt nt]]
This suppresses all normal trace information. This option is useful if the \tt count or \tt timer options are used and you are interested in the statistics but not the function calling information.

\item[\tt off]]
causes untracing of all or specific functions. Without an argument, all functions, constructors, domains and packages are untraced. Otherwise, the given functions and other objects are untraced. To immediately retrace the untraced functions, issue \tt trace
\item{\tt )only \ \{it listOfDataToDisplay\}}
causes only specific trace information to be shown. The items are
listed by using the following abbreviations:
\begin{items}
\item{\tt [a]} display all arguments
\item{\tt [v]} display return value
\item{\tt [1]} display first argument
\item{\tt [2]} display second argument
\item{\tt [15]} display the 15th argument, and so on
\end{items}
\item{\tt )restore}\}
causes the last untraced functions to be retraced. If additional
options are present, they are added to those previously in effect.
\item{\tt )stats}\}
causes the display of statistics collected by the use of the
\{\tt )count\} and \{\tt )timer\} options.
\item{\tt )stats reset}\}
resets to 0 the statistics collected by the use of the
\{\tt )count\} and \{\tt )timer\} options.
\item{\tt )timer}\}
causes the system to keep a count of execution times for the
traced function. The total can be displayed with \{\tt )trace
)stats\} and cleared with \{\tt )trace )stats reset\}.
%!! only for lisp, boot, may not work in any case, recommend removing
%\item{\tt )varbreak}\}
%causes a \Lisp{} break loop to be entered after
%the assignment to any variable in the traced function.
\item{\tt )varbreak} \{\it var1 \lanb{}... varN\ranb{}\}}
causes a \Lisp{} break loop to be entered after
the assignment to any of the listed variables in the traced
function.
\item{\tt )vars}\}
causes the display of the value of any variable after it is assigned
in the traced function. Note that library code must have been
compiled (see
\item\[\tt (\texttt{vartrace})\]\causes the display of the value of any of the specified variables after they are assigned in the traced function. Note that library code must have been compiled (see \downlink{``)compile''}{ugSysCmdcompilePage} in Section B.7\ignore{ugSysCmdcompile}) using the \texttt{vartrace} option in order to support this option.

\item\[\tt (\texttt{within})\]\causes the display of trace information only if the traced function is called when the given \texttt{executingFunction} is running.

The following are the options for tracing constructors, domains and packages.

\item\[\tt (\texttt{local})\]\causes local functions of the constructor to be traced. Note that to untrace an individual local function, you must use the fully qualified internal name, using the escape character \spadSyntax{\_} before the semicolon.

\begin{verbatim}
)trace FRAC )local
)trace FRAC_;cancelGcd )off
\end{verbatim}

\item\[\tt (\texttt{ops})\]\By default, all operations from a domain or package are traced when the domain or package is traced. This option allows you to specify that only particular operations should be traced. The command

\begin{verbatim}
% )trace Integer )ops min max _+ _-
\end{verbatim}

\end{verbatim}

\begin{verbatim}
traces four operations from the domain \spadtype{Integer}. Since \tt{+} and \tt{-} are special characters, it is necessary to escape them with an underscore.

\end{verbatim}

\begin{page}{ugSysCmdundoPage}{B.27. }undo\}
\beginscroll

\par\noindent{\bf User Level Required:} interpreter

\par\noindent{\bf Command Syntax:}
\begin{itemize}
\item{\tt )undo}
\item{\tt )undo} {\it integer}
\item{\tt )undo} \{\it integer \lanb{option\ranb{}}
\item{\tt )undo} {\tt )redo}
\end{itemize}
% where {\it option} is one of
% \begin{itemize}
% \item{\tt )after}
% \item{\tt )before}
% \end{itemize}

\par\noindent{\bf Command Description:}

This command is used to
restore the state of the user environment to an earlier
point in the interactive session.
The argument of an {\tt )undo} is an integer which must designate some
step number in the interactive session.

\begin{verbatim}
)undo n
\end{verbatim}
These commands return the state of the interactive environment to that immediately after step \{\tt n\}.
If \{\tt n\} is a positive number, then \{\tt n\} refers to step number \{\tt n\}. If \{\tt n\} is a negative number, it refers to the \eth\{\tt n\} previous command (that is, undoes the effects of the last \smath{-n} commands).

A \{\tt clear all\} resets the \{\tt undo\} facility. Otherwise, an \{\tt undo\} undoes the effect of \{\tt clear\} with options \{\tt properties\}, \{\tt value\}, and \{\tt mode\}, and that of a previous \{\tt undo\}.
If any such system commands are given between steps \smath{n} and \smath{n + 1} (\smath{n > 0}), their effect is undone for \{\tt undo m\} for any \texttt{\{smath{0 < m \leq n}\}} \{0 < m \leq n\}.

The command \{\tt undo\} is equivalent to \{\tt undo -1\} (it undoes the effect of the previous user expression).
The command \{\tt undo 0\} undoes any of the above system commands issued since the last user expression.

This command returns the state of the interactive environment to that immediately before step \{\tt n\}.
Any \{\tt undo\} or \{\tt clear\} system commands given before step \{\tt n\} will not be undone.

This command reads the file \{\tt redo.input\}. created by the last \{\tt undo\} command.
This file consists of all user input lines, excluding those backtracked over due to a previous \{\tt undo\}.

\par\noindent{\bf Also See:} \downlink{``)history''}{ugSysCmdhistoryPage} in section B.13
The command \{\tt )history )write\} will eliminate the ‘‘undone’’ command lines of your program.
\begin{page}{ugSysCmdwhatPage}{B.28. )what}
\beginscroll

\par\noindent\bf User Level Required:} interpreter

\par\noindent\bf Command Syntax:}
\begin{items}
\item{\tt )what categories} {\it pattern1} \lanb{}
{\it pattern2 ...\ranb{}}
\item{\tt )what commands } {\it pattern1} \lanb{}
{\it pattern2 ...\ranb{}}
\item{\tt )what domains } {\it pattern1} \lanb{}
{\it pattern2 ...\ranb{}}
\item{\tt )what operations} {\it pattern1} \lanb{}
{\it pattern2 ...\ranb{}}
\item{\tt )what packages } {\it pattern1} \lanb{}
{\it pattern2 ...\ranb{}}
\item{\tt )what synonym } {\it pattern1} \lanb{}
{\it pattern2 ...\ranb{}}
\item{\tt )what things } {\it pattern1} \lanb{}
{\it pattern2 ...\ranb{}}
\item{\tt apropos } {\it pattern1} \lanb{}
{\it pattern2 ...\ranb{}}
\end{items}

\par\noindent\bf Command Description:}

This command is used to display lists of things in the system. The patterns are all strings and, if present, restrict the contents of the lists. Only those items that contain one or more of the strings as substrings are displayed. For example,
\begin{verbatim}
)what synonym
\end{verbatim}
displays all command synonyms,
\begin{verbatim}
)what synonym ver
\end{verbatim}
displays all command synonyms containing the substring ‘‘{\tt ver}’’,
\verb|
\begin{verbatim}
what synonym ver pr
\end{verbatim}

\begin{verbatim}

displays all command synonyms containing the substring \verb|"{\tt ver}"| or the substring \verb|"{\tt pr}"|.
Output similar to the following will be displayed
\end{verbatim}

---------------- System Command Synonyms ----------------
user-defined synonyms satisfying patterns:

\begin{verbatim}
  ver pr
\end{verbatim}

\begin{verbatim}
apr ......................... \what things
apropos ....................... \what things
prompt ......................... \set message prompt
version ....................... \lisp *yearweek*
\end{verbatim}

\begin{verbatim}
\end{verbatim}

Several other things can be listed with the \tt{\什么} command:

\begin{verbatim}
\item[\tt categories] displays a list of category constructors.
\item[\tt commands] displays a list of system commands available at your user-level.
Your user-level is set via the \tt{\set userlevel} command.
To get a description of a particular command, such as \tt{\what}, issue \tt{\help \what}.
\item[\tt domains] displays a list of domain constructors.
\item[\tt operations] displays a list of operations in the system library. It is recommended that you qualify this command with one or more patterns, as there are thousands of operations available. For example, say you are looking for functions that involve computation of eigenvalues. To find their names, try \tt{\what operations eig}. A rather large list of operations is loaded into the workspace when this command is first issued. This list will be deleted when you clear the workspace via \tt{\clear all} or \tt{\clear completely}. It will be re-created if it is needed again.
\item[\tt packages] displays a list of package constructors.
\item[\tt synonym] lists system command synonyms.
\item[\tt things] displays all of the above types for items containing the pattern strings as substrings.
The command synonym \tt{\apropos} is equivalent to \tt{\what things}.
\end{verbatim}

\begin{verbatim}
\end{verbatim}

Chapter 20

Users Guide Chapter 21 (ug21.ht)

Programs for Axiom Images

— ug21.ht —

This appendix contains the Axiom programs used to generate the images in the \Gallery{} color insert of this book. All these input files are included with the Axiom system. To produce the images on page 6 of the \Gallery{} insert, for example, issue the command:

\begin{verbatim}
)read images6
\end{verbatim}

These images were produced on an IBM RS/6000 model 530 with a standard color graphics adapter. The smooth shaded images were made from X Window System screen dumps. The remaining images were produced with Axiom-generated PostScript output. The images were reproduced from slides made on an Agfa ChromaScript PostScript interpreter with a Matrix Instruments QCR camera.

\noindent

\newpage
\endscroll
\autobuttons
\end{page}
These images illustrate how Newton's method converges when computing the complex cube roots of 2. Each point in the \((x,y)\)-plane represents the complex number \(x + iy\), which is given as a starting point for Newton's method. The poles in these images represent bad starting values. The flat areas are the regions of convergence to the three roots.

The function \(f^n\) computes \(n\) steps of Newton's method.

  12.
  fun := ngeneralTube(spaceCurve,planeCurve,delT,oldT)
  13.
  draw(fun, uRange, tRange, l)
}

userfun{nFrenetFrame}{c, t, delT}
numerically computes the Frenet frame about the curve \{c\} at \{t\}.
Parameter \{delT\} is a small number used to compute derivatives.

userfun{ngeneralTube}{spaceCurve, planeCurve, delT, oldT}
creates a function that can be passed to the system axiomFun{draw} command.
The function is a parameterized surface for the general tube around \{spaceCurve\}.
\{delT\} is a small number used to compute derivatives. \{oldT\} is used to hold the current value of the \{t\} parameter for \{spaceCurve\}.
This is an efficiency measure to ensure that frames are only computed once for each value of \{t\}.

\end{scroll}

In order to draw Antoine rings, we take one ring, scale it down to a smaller size, rotate it around its central axis, translate it to the edge of the larger ring and rotate it around the edge to a point corresponding to its count (there are 10 positions around the edge of the larger ring). For each of these new rings we recursively perform the operations, each ring becoming 10 smaller rings. Notice how the \axiomType{DHMATRIX} operations are used to build up the proper matrix composing all these transformations.

Input Areas

You have probably seen input areas in other Hyperdoc pages. They provide "dynamic link" capabilities. Instead of having a choice between certain actions, they allow you to specify an action on-the-fly. To use them, you need the following commands:

```
{\tt \inputstring\{{\it label}\}\{\it length}\}\{\it default value\}}
{\tt \stringvalue\{{\it label}\}}
```

The first command puts up an input area of the \{\it length\} specified. The \{\it default value\} is placed in it. The first argument, \{\it label\} gives a name to the contents of the input area. You can refer to those contents by using the second command. Never place a \{\tt \stringvalue\} command in an "exposed" part of the page. It is only meant to be used as an argument to an \{\it action\}. Here are some examples.

```

Radio buttons

\begin{page}{HTXAdvPage2}{Radio buttons}
\centerline{\fbox{{\tt \thispage}}}
\begin{scroll}

If you just want to make a multiple-choice type selection, why not use the {\it radio buttons}.

You need to use bitmaps for the active areas (the buttons) but Hyperdoc will keep track of the currently activated button. You can use this boolean information somewhere else on your page. The commands to use are:

\begin{Important}
\end{Important}

\tt \radioboxes{\{\it group name\}}{\{\it bitmap file1\}}{\{\it bitmap file0\}}
\tt \radiobox{\{\it initial state\}}{\{\it label\}}{\{\it group name\}}
\tt \boxvalue{\{\it label\}}

The \tt \radioboxes command sets up a group of \tt \radiobox buttons. The \tt {\it group name} is a label for the group. The filenames for the bitmaps are specified in \tt {\it bitmap file1} and \tt {\it bitmap file0}. The first one should denote an activated button and the second a de-activated one.

To display each button in a group, use \tt \radiobox. The \tt {\it initial state} should be either \tt 1 or \tt 0 depending on whether the button should first be displayed as activated or not. The second \tt {\it label} argument defines the name by which the current state of the button can be referred to. The third argument specifies which group this button belongs to.

The \tt \boxvalue command can then be used in various
actions. The value of it will be either \tt t or \tt nil.

In the example below, we use the \tt \htbmfile macro defined in \tt util.ht so that we do not have to write the full bitmap file pathnames.

This is how we set up the group. The \tt \radioboxes command does not display anything.
Note that these commands cannot be included in a \tt \patch. This is why we display this time the source and the result at the same time.
\beginImportant
\beginverbatim
\radioboxes\{group\}
\{\htbmfile\{pick\}\}\{\htbmfile\{unpick\}\}
\table{
\radiobox[1]\{b1\}\{group\}
\radiobox[0]\{b2\}\{group\}
\radiobox[0]\{b3\}\{group\}
}
\lispcommand\{lisp\}{(pprint (list
\boxvalue{b1} \boxvalue{b2} \boxvalue{b3}))}
\ unixcommand\{unix\}{echo '\boxvalue{b1}
\boxvalue{b2} \boxvalue{b3}'
\endverbatim\endImportant

You can only set one radio button at a time. If you want a non-exclusive selection, try \tt \inputbox. The syntax for this command is
\beginImportant
\beginverbatim
\inputbox[\tt \it initial state]\{\tt \it label\}\{\tt \it bitmap file1\}\{\tt \it bitmap file0\}
\endverbatim\endImportant
There is no group command for these.

Note that the \textit{initial state} is an optional argument. If omitted the button will initially be deactivated.
21.3  htxadvpage3.ht

Macros

⇒ “notitle” (HTXAdvPage4) 21.4 on page 2619
— htxadvpage3.ht —

\begin{page}{HTXAdvPage3}{Macros}
\centerline{\fbox{{\tt \thispage}}}\newline
\begin{scroll}

Sometimes you may find yourself having to write almost the same piece of Hyperdoc text many times. Thankfully, there is a command to ease the work. It is the \tt \newcommand command and provides a macro facility for Hyperdoc. In this way, you can give a short name to a sequence of Hyperdoc text and use that name to include the sequence in your pages. The way this works is the following
\beginImportant
\newline
\centerline{{\tt \newcommand\{\it name\}\[\it number of arguments\]\{\it Hyperdoc text\}\}}
\endImportant

and here is an example from \bf util.ht
\beginImportant
\newline
{\tt \newcommand\{\axiomSig\}[2]
{\axiomType\{\#1\}\ {\tt ->}\ \axiomType\{\#2\}\}}
\newline
{\tt \newcommand\{\axiomType\}[1]
{\lispdownlink\{\#1\}\{{\spadType\ '\mid\#1\}\}}}
\endImportant

You see that a macro’s definition can invoke another. Don’t create a circular definition though!

Notice how the arguments of the macro are used in the definition. The {\tt \#{\it n}} construct is the place--holder of the {\it n}’th argument.

To use the macro, just treat it as an ordinary command. For instance
\beginImportant
\newline
{\tt \axiomSig\{Integer\}\{List Integer\}}
21.4 \textit{htxadvpagen4.ht}

\begin{page}{HTXAdvPage4}{Patch and Paste}

\end{scroll}
\begin{scroll}
\begin{important}
\begin{axiomSig}{Integer}\{\text{List Integer}\}
\end{important}
\end{scroll}

The best way to familiarise yourself to macros is to study the macros defined in \centerline{\{\itbf util.ht\}}
It is highly probable that a good many of them will prove useful to you.
Clever use of macros will allow you to create Hyperdoc text that can be formatted by other programs (such as TeX).
The Axiom User Guide was written in such a way as to make translation in Hyperdoc form and TeX form a mechanical process.

\end{important}
\end{scroll}
\begin{scroll}
\begin{important}

Patch and Paste

⇒ “notitle” \textit{(HTXAdvPage5) 21.5 on page 2623}

\begin{page}{HTXAdvPage4}{Patch and Paste}
\centerline{\fbox{\texttt{\thispage}}}\newline
\begin{scroll}
A powerful Hyperdoc feature is the ability to \{\it replace\}
part of a displayed page with another part when an active area is clicked. The group commands\{\it patch\} and \{\it paste\} offer this facility.
A \{\it paste\} region can appear anywhere

\end{scroll}
\end{page}
within a page or a \{it patch\}. A \{it patch\} region must be defined outside a page definition.

We need a few objects to define the \{it paste\} region. These are a \{it name\} with which to refer to it, some way of specifying what it is to be replaced by and a \{it trigger\} for the replacement. A \{it patch\} is how we specify the second of these objects. The \{it patch\} is generally a sequence of Hyperdoc text.

If we want to have the option of returning to the original (or, indeed, proceeding to a \{it third\} alternative) we clearly must include a \{it paste\} in the \{it patch\}.

Let us start with a simple example. We wish to have the word \{tt initial\} somewhere on the page replaced by the word \{tt final\} at a click of a button. Let us first define the \{it patch\}. It will just contain the word \{tt final\}. Here is a definition of a patch called \{tt patch1\} (note that the actual definition must be outside this page’s definition).
\beginImportant
\begin{center}
\begin{verbatim}
begin\{patch\}\{patch1\}
final
end\{patch\}
\end{verbatim}
\end{center}
\endImportant
We now define a \{it paste\} region exactly where we want the word \{tt initial\} to appear.
\beginImportant
\begin{verbatim}
begin\{paste\}\{paste1\}\{patch1\}
initial
end\{paste\}
\end{verbatim}
\endImportant
We have specified first the name of the \{it paste\} region which is \{tt paste1\} and then the name of the replacement \{it patch\} which is \{tt patch1\}. Something is missing -- the trigger. To include a trigger we write
\beginImportant
\begin{verbatim}
pastebutton\{paste1\}\{trigger\}
\end{verbatim}
\endImportant
This new command {	t \pastebutton} displays the second argument as an active area. The first argument specifies the {	t \it paste} region it refers to. Clicking on {	t trigger} above will replace the word {	t initial} with the word {	t final}.

We can, if we like, include the {	t \pastebutton} in the {	t \it paste} region. Let us improve on the situation by providing a way of going back to the original word {	t initial} on the page. The {	t \it patch} must itself include a {	t \it paste}. What will the replacement {	t \it patch} for this new {	t \it paste} be? Well, we have to define a second {	t \it patch} that contains all the stuff in the original {	t \it paste} region. Here is the updated {	t \it patch} for the first replacement.

The {	t \MenuDotBitmap} macro is defined in {	t \bf util.ht}. It displays a button bitmap. This time we put the {	t \pastebutton} inside the {	t \it paste}.

Remember that these {	t \it patch} definitons must occur outside a {	t \begin{page} - \end{page}} group. What is left now is to define the starting {	t \it paste} region.

\beginImportant
\newline
\{\tt \begin{patch}\{Patch1\}\newline
\{\tt \begin{paste}\{Paste1\}\{Patch1\}\newline
\{\tt \pastebutton\{Paste1\}\{\MenuDotBitmap\}\newline
\{\tt final\newline
\{\tt \end{patch}\newline
\{\tt \end{patch}\newline
\endImportant

\beginImportant
\newline
\{\tt \begin{patch}\{Patch2\}\newline
\{\tt \begin{paste}\{Paste2\}\{Patch2\}\newline
\{\tt \pastebutton\{Paste2\}\{\MenuDotBitmap\}\newline

\endImportant

\beginImportant
\newline
\{\tt \begin{patch}\{Patch\}\newline
\{\tt \begin{paste}\{Paste\}\newline
\{\tt \pastebutton\{Paste\}\{\MenuDotBitmap\}\newline
\{\tt initial\newline
\{\tt \end{patch}\newline
\{\tt \end{patch}\}

Remember that these {	t \it patch} definitons must occur outside a {	t \begin{page} - \end{page}} group. What is left now is to define the starting {	t \it paste} region.

\beginImportant
\newline
\{\tt \begin{patch}\{Patch\}\newline
\{\tt \begin{paste}\{Paste\}\{Patch\}\newline
\{\tt \pastebutton\{Paste\}\{\MenuDotBitmap\}\newline
\{\tt initial\newline
\{\tt \end{patch}\newline
\{\tt \end{patch}\}
Clicking on the button above next to \texttt{initial} will replace the \texttt{Paste1} region with \texttt{Patch1}. That \texttt{Patch1} also contains a \texttt{Paste2} region. Clicking on its button will put up \texttt{Patch2} which has a \texttt{Paste3} region. Clicking on its button will put up \texttt{Patch1} again. In that way, we close the chain of replacements.
21.5  HTXADVPAGE5.HT

\begin{page}{HTXAdvPage5}{Axiom paste-ins}
\centerline{\fbox{{\tt \thispage}}}\newline
\begin{scroll}
The \textit{paste} and \textit{patch} facility
(see \downlink{previous page}{HTXAdvPage4})
is used to display (or hide) the Axiom output
of an Axiom command ({{\tt \axiomcommand}})
included in a
Hyperdoc page.
\end{scroll}

A mechanism has been set up to \textit{automatically} generate
these paste-ins. It amounts to replacing an
{{\tt \axiomcommand}} by a {{\tt \pastecommand}} in the
In the case of a `\axiomOp{draw}` Axiom command, where the result is to create an interactive viewport, the appropriate command to use is `{\tt \pastegraph}`. The effect of this is to include (as the output) the Axiom generated `{\it image}` of the graph as an active area. Clicking on it will put up an interactive viewport. The `{\tt \pastegraph}` command should be used only when the result of the associated Axiom operation is to `{\it create}` an interactive viewport. It is `{\it not}` necessarily appropriate for all commands whose result is a `{\axiomType{Two{}Dimensional{}Viewport}}` or `{\axiomType{Three{}Dimensional{}Viewport}}`. The `{\tt \pastecommand}` and `{\tt \pastegraph}` are macros defined in `{\bf util.ht}`.

There is no automatic paste-in generation facility for Axiom piles (the `{\tt \begin{axiomsrc}}` command).

The automatic paste-in generation mechanism works by invoking Axiom with a particular option. Hyperdoc is also started automatically. It reads the `{\tt \pastecommand}` and `{\tt \pastegraph}` commands in all pages in a specified `{\bf somefile.ht}` and passes them to Axiom for evaluation. Hyperdoc captures the output and writes it out (to a file called `{\bf somefile.pht}`) as the body of some `{\it patch}` definitions. The commands encountered are written to a file `{\bf somefile.input}` which you can `{\tt \read}` from an Axiom session. It also creates directories for the graphics images encountered. Those files and directories will be written under the `{\it current}` directory. The idea is that you then include the `{\it patch}` definitions in `{\bf somefile.pht}` in your local database using `{\bf htadd}`.

You can try this feature now. Edit a file called, say, `{\bf trypaste.ht}` in a directory, say `{\bf /tmp}`. Put the following Hyperdoc text in it.

```
\beginImportant
\newline
{\tt \begin{page}\{TryPaste\}\{Trying out paste-in generation\}\newline
{\tt \begin{scroll}\newline
{\tt \pastecommand\{f z == z**2 \bound\{f\}\}}\newline
{\tt \pastegraph\{draw(f,-1..1) \free\{f\}\}}\newline
{\tt \pastecommand\{x:= f 3 \free\{f\}\}}\newline
{\tt \end{scroll}\}}\newline
\endImportant
```

Hyperdoc page.
From the directory that contains the \texttt{trypaste.ht},
issue
\begin{verbatim}
htadd -l ./trypaste.ht
\end{verbatim}
You will get the \texttt{ht.db} database file.
Set the environment variable \texttt{HTPATH} so that it points first to your directory and then the system directory.
In the \texttt{/bin/csh}, you might use
\begin{verbatim}
setenv HTPATH /tmp:$$AXIOM/doc
\end{verbatim}
Make sure that no \texttt{trypaste.input} or \texttt{trypaste.pht} files exist in the directory.
Then issue
\begin{verbatim}
axiom -paste trypaste.ht
\end{verbatim}
and wait for Axiom to finish.

There is a modification you will wish to make to the \texttt{trypaste.pht} file.
This is because the generated Hyperdoc text will assume that the \texttt{viewport} data will be located in the \texttt{system} directory.
\begin{verbatim}
\env{AXIOM}/doc/viewports
\end{verbatim}
You may want to place your images in a different directory, say, \texttt{/u/sugar/viewports}.
If so, then change all occurrences of
\begin{verbatim}
\env{AXIOM}/doc/viewports/
\end{verbatim}
in the file \texttt{trypaste.pht}. The last step is to include the \texttt{patch} definitions in \texttt{trypaste.pht} to your local database.
Issue
\begin{verbatim}
htadd -l ./trypaste.pht
\end{verbatim}
to update the database. If you have provided a link to your pages from the \texttt{RootPage} via the \texttt{\localinfo} macro, you should now
be able to start Axiom or Hyperdoc
and see the computed Axiom output whenever you
click on the buttons to the left of each command.

21.10 htxformatpage3.ht

Using different fonts
Using different fonts

You can use various fonts for the text. Hyperdoc makes four \{em logical\} fonts available to you: a \{em roman\} font, an \{em emphasised\} font, a \{em bold\} font and a \{em typewriter\} font. The actual font that corresponds to each logical font is determined by the end user via a defaults file. The colour for each of these fonts can also be specified.

Normal text is displayed with the roman font. If you want to emphasize some text, use the \{tt \em\} command in the following way.

\beginImportant
\begin{paste}{HTXFormatPage3xPaste1}{HTXFormatPage3xPatch1}
\pastebutton{HTXFormatPage3xPaste1}{Interpret}
\newline
\{tt this is \{\em emphasised\} text\}
\end{paste}
\endImportant

Note the use of the braces to enclose command and "arguments". All font commands are specified in the same way. The \{tt \em\} command will in fact \{em switch\} between roman and emphasised font every time it is used.

\beginImportant
\begin{paste}{HTXFormatPage3xPaste2}{HTXFormatPage3xPatch2}
\pastebutton{HTXFormatPage3xPaste2}{Interpret}
\newline
\{tt this is \{\em emphasised\} text\}
\end{paste}
\endImportant

If you want to be sure that the emphasized font will be used, specify the \{tt \it\} command. Similarly, you can explicitly select the roman font with the \{tt \rm\} command.

\beginImportant
\begin{paste}{HTXFormatPage3xPaste3}{HTXFormatPage3xPatch3}
\pastebutton{HTXFormatPage3xPaste3}{Interpret}
\newline
\{tt this is \{\it emphasised\} text and this is \{\rm roman\}\}
\end{paste}
\endImportant

The bold font is selected with the \{tt \bf\} command and the typewriter font with the \{tt \tt\} command. All these commands can be applied to individual characters, words, sentences etc.
Currently, Hyperdoc does not adjust its internal spacing rules to each font individually. This means that, for consistent results, users are encouraged to specify (in the defaults file) "character-cell" fonts that are not too small or too large for Hyperdoc. Here is the correspondence between the above font commands and the defaults names:

- \emph{\texttt{\rm}} or \texttt{\em}
- \textbf{\texttt{\bf}}
- \textit{\texttt{\it}} or \texttt{\em}
- \texttt{\tt}

Hyperdoc uses two more logical fonts that can be specified by the end user: AxiomFont and ActiveFont. However, you cannot explicitly use these fonts in your text. The ActiveFont is automatically used for active area text and the AxiomFont is reserved for active Axiom commands.

21.11 \textit{htxformatpage4.ht}

\textbf{Indentation}

\begin{center}
\begin{tabular}{|c|c|}
\hline
\textbf{htxformatpage4.ht} & \\
\hline
\end{tabular}
\end{center}

\begin{page}{HTXFormatPage4}{Indentation}
\centerline{\fbox{\tt \thispage}}
\begin{scroll}
\end{scroll}
\end{page}
You can control the indentation of lines of text in Hyperdoc with some useful commands.

Use the command `\par` to force a new paragraph if you don't want to use the blank-line rule. The first line of a new paragraph will normally be indented by a standard small amount. If you just want to start on a new line, use the `\newline` command.

\begin{important}
\begin{paste}{HTXFormatPage4xPaste1}{HTXFormatPage4xPatch1}
\pastebutton{HTXFormatPage4xPaste1}{Interpret}
\newline
{\tt let us start a new line \newline here }
\newline
\end{paste}
\end{important}

The command `\indent{{\it value}}` will set the left-page-margin `\it value` characters to the right of the standard left-page-margin. The initial (standard) state of a page can be reset by the `\indent{0}` command. The first lines of paragraphs will be indented by the `\it extra` standard amount. The `\indent{{\it value}}` command does \emph{not} force a new line or paragraph.

You can also use the `\indentrel{{\it value}}` command. Here, the `\it value` argument is a `\em relative` indentation which can be positive or negative. Otherwise, it behaves in the same way as the `\indent` command.

\begin{important}
\begin{paste}{HTXFormatPage4xPaste2}{HTXFormatPage4xPatch2}
\pastebutton{HTXFormatPage4xPaste2}{Interpret}
\newline
{\tt previous text. \indentrel{10} here }
\newline
{\tt \indentrel{-5} there}\newline
{\tt \indentrel{-5} back}
\newline
\end{paste}
\end{important}

The `\centerline{{\it some text}}` command will center its argument between the current left and right margins. The argument of the command should not be more than a paragraph of text and should not contain any commands that change the left margin. The centered text will start on a new line.

\begin{important}
\begin{paste}{HTXFormatPage4xPaste3}{HTXFormatPage4xPatch3}
\pastebutton{HTXFormatPage4xPaste3}{Interpret}
\newline
\end{important}

{\tt previous text. \centerline{This could}\newline
{\tt be some heading.} Carry on}
Placing text in vertically aligned columns is easily done with the \{\tt \tab\{{\it value}\}} command. The \{\tt \tab\} command has the immediate effect of placing the next word \{\it value\} characters to the right of the current left margin.

\begin{paste}{HTXFormatPage4xPaste4}{HTXFormatPage4xPatch4}
\pastebutton{HTXFormatPage4xPaste4}{Interpret}
\newline
{\tt \indent\{5\}\newline}
{\tt Team A \tab\{17\}Score\tab\{25\}Team B\tab\{42\}Score\newline}
{\tt 01234567890123456789012345678901234567890\newline}
{\tt Green-Red\tab\{17\}4\tab\{25\}Blue-Black\tab\{42\}6\newline}
{\tt \indent\{0\}}
\end{paste}
\end{scroll}

If you wish to preserve the indentation of a piece of text you can use the \{\tt verbatim\} group command. Simply place a \{\tt \begin\{verbatim\}\} and \{\tt \end\{verbatim\}\} around the text. Note that Hyperdoc commands will not be interpreted within the \{\tt verbatim\} group.

\begin{paste}{HTXFormatPage4xPaste5}{HTXFormatPage4xPatch5}
\pastebutton{HTXFormatPage4xPaste5}{Interpret}
\newline
{\tt \begin\{verbatim\}}
\begin{verbatim}
This spacing will be preserved
{\bf is} preserved
\end{verbatim}
{\tt \end\{verbatim\}}
\end{paste}
\end{scroll}

Creating Lists and Tables

\begin{page}{}{Creating Lists and Tables}
\centerline{\fbox{{\tt thispage}}}
\begin{scroll}
The \{tt \begin\{items\} {\rm -} \end\{items\}\} group command constructs itemized lists. The \{tt \item\} command separates the items in the list. The indentation rules for the list group are different from those of a paragraph. The first line of an item will normally extend further to the left than the rest of the lines. Both commands accept \{em optional\} arguments. Optional arguments are enclosed in square brackets (\{tt [ ]\}) rather than braces.

The indentation of subsequent lines in an item is determined by the optional argument \{it some text\} in the \{tt \begin\{items\}\{\it some text\}\} command. The optional argument is \{em not\} displayed. Its width is calculated and used to indent all subsequent lines in the group except from the first line of each new item. This indentation rule applies to all text \{em before\} the first \{tt \item\} command as well.

The \{tt \item[\{it some text\}]\} command specifies the start of a new item. The \{it some text\} optional argument will be displayed in \{em bold\} font at the current left-page-margin. Then, the text following the command will be displayed in normal fashion with the above indentation rule.

\begin{important}
\begin{paste}{HTXFormatPage5xPatch1}{HTXFormatPage5xPaste1}
\pastebutton{HTXFormatPage5xPatch1}{Interpret}
\newline
{\tt indent\{5\}}
{\tt \begin\{items\}\{how wide am I\}\} newline
{\tt Here we carry on but a \{newline\} newline
{\tt \item[how wide am I] fits nicely.
Here is a \{newline\} newline
{\tt \item[again] to show another item\} newline
{\tt \item[\\tab\{0\}] can be used \{\\tab\{15\}\} effectively}
\newline
\end{important}
Note that the \{\tt \begin\{items\}\} command immediately sets the left-page-margin to a new value. Subsequent \{\tt \tab\} or \{\tt \centerline\} commands refer to this new margin. Any explicit margin setting commands included in the group \{em will\} have the normal effect. The \{\tt \par\} command does not produce the standard paragraph indentation within a list group --- it behaves instead like \{\tt \newline\}.

You can nest list groups like the following example suggests.
\beginImportant
\begin{paste}{HTXFormatPage5xPaste2}{HTXFormatPage5xPatch2}
\pastebutton{HTXFormatPage5xPaste2}{Interpret}
\newline
\{\tt \begin\{items\}\[quitealot\]\}
\newline
\{\tt A nested list:}\newline
\{\tt \item[The first\] item of an itemized list is on this line.}\newline
\newline
\{\tt \item[The second\] item of the list starts here. It contains another}\newline
\{\tt list nested inside it.}\newline
\{\tt \begin\{items\}\[somuchmore\]\}
\newline
\{\tt \item[First]\tab\{0\}This is the first item of an enumerated}\newline
\{\tt list that is nested within the itemized list.}\newline
\{\tt \item[Second]\tab\{0\}This is the second item of the inner list.}\newline
\{\tt \end\{items\}\}
\newline
\{\tt This is the rest of the second item of the outer list. It}\newline
\{\tt is no more interesting than any other part of the item.}\newline
\{\tt \item[The third\] item of the list.}\newline
\{\tt \end\{items\}\}
\end{paste}
\endImportant

Another facility for presenting lists is the \{\tt \table\} command. The correct syntax for it is: \{\tt \table\{"\{\item a\}\}"\{\tt \item b\}\} \{\tt \ldots\}\. The items in the braces will be placed in as many aligned columns as is possible for the current window dimensions or page width. If one item is particularly long there will probably be only one column in the table. Here is a table of color names.
\begin{Important}
\begin{paste}{HTXFormatPage5xPaste3}{HTXFormatPage5xPatch3}
\newline
{\tt

There are three commands that one can use to exercise finer control over the appearance of text on a page: \tt{\space}, \tt{\hspace} and \tt{\vspace}.

The \tt{\space\{{\it value}\}} command accepts an integer argument and simply changes the position of the next character to the right or to the left. A negative argument will move the next character to the left and a positive one to the right. The unit of movement is \it{the width of a character}. In this way one can overstrike characters to produce various effects.

\beginImportant
\begin{paste}{HTXFormatPage7xPaste1}{HTXFormatPage7xPatch1}
\pastebutton{HTXFormatPage7xPaste1}{Interpret}
\newline
\tt 0\space\{-1\}\__________
\tt underlined\space\{-10\}\__________
\end{paste}
\endImportant

The \tt{\hspace\{{\it value}\}} command is similar to the \tt{\space\{{\it value}\}} command. It also accepts an integer argument and changes the position of the next character to the right or to the left. A negative argument will move the next character to the left and a positive one to the right. The unit of movement is \it{a pixel}. The \tt{\it value} argument specifies an offset from the default placement of the character.

\beginImportant
\begin{paste}{HTXFormatPage7xPaste2}{HTXFormatPage7xPatch2}
\pastebutton{HTXFormatPage7xPaste2}{Interpret}
\newline
\tt x\hspace\{-4\}x\hspace\{-3\}x\hspace\{-2\}x\hspace\{-1\}x\%
\tt x\hspace\{1\}x\hspace\{2\}x\hspace\{3\}x\hspace\{4\}x
\end{paste}
\endImportant

The \tt{\vspace\{{\it value}\}} command is similar to the \tt{\hspace\{{\it value}\}} command but (as the name suggests) works in the vertical direction. The unit of movement is \it{a pixel}. The \tt{\it value} argument specifies an offset from \it{the next line}. A negative argument moves the next character up and a positive down. This command can be used for subscripts and superscripts. One drawback in the use of \tt{\vspace} is that it can only work with a particular font at a time. This is because the inter-line spacing depends on the font being used and the value of it is needed to get "back" on the line.
In general, the command {\tt \vspace\{{\it - ils}\}} will have a null effect when \{{\it ils}\} = ( font ascent + font descent + 5 ). The example below assumes that \{{\it ils}\} = 25 e.g. the Rom14 font on the RISC System/6000.

Bitmaps and Images

\begin{page}{HTXFormatPage8}{Bitmaps and Images}
\centerline{\fbox{\tt \thispage}}

The commands \tt \inputbitmap{{\it filename}} and \tt \inputimage{{\it filename}} allow you to include an X11 bitmap or an Axiom-generated viewport in a Hyperdoc page.

In the case of the \tt \inputbitmap command the \tt \{it filename\} parameter must be the full pathname of an X11 bitmap file.

\beginImportant
\begin{paste}{HTXFormatPage8xPaste1}{HTXFormatPage8xPatch1}
\pastebutton{HTXFormatPage8xPaste1}{Interpret}
\newline
\tt \inputbitmap{{\env{AXIOM}/doc/bitmaps/sup.bitmap}}
\end{paste}
\endImportant

The \tt \inputimage command will automatically select the \tt \{it image.xpm\} or the \tt \{it image.bm\} file for you based on the capabilities of your X server.
For your convenience, there are two macros defined in \centerline{\{\bf util.ht\}.}
The \{\tt \viewport\} macro eliminates the need to specify
the \{\tt .view/image\} part and the
\{\tt \axiomViewport\} macro automatically selects viewport
files in the system directories. The above \{\tt \inputimage\}
could have been written
\beginImportant
\{\tt \viewport\{\env{AXIOM}/doc/viewports/ugProblemNumericPage30\}\}
\endImportant
or
\beginImportant
\{\tt \axiomViewport\{ugProblemNumericPage30\}\}

\end{scroll}

What Hyperdoc does

Take a close look at the objects in the Hyperdoc window you are now reading. Most of them are text. Resize the window using the window manager facilities. The text is reformatted to fit the window border. This action is performed by Hyperdoc. At the simplest level, it provides a method for \{em formatting\} text in a window. In fact, it can place other things on the window as well, such as bitmaps or color images. The \{em buttons\} you see at either side at the top of
the window are bitmaps.

Move the cursor so that it rests on one of those buttons. You notice that the cursor has changed appearance. This indicates that there is an action associated with the button. This action will be performed when you click the mouse button over the active area. If you are familiar with Hyperdoc, you know that the active area can be words, bitmaps, images or input areas. In fact, anything that can be displayed in a Hyperdoc window can be an active area.

So, what can the action associated with an active area be? Hyperdoc allows quite a bit of freedom in defining that action. We will have a close look at this issue later on. For now, recall the various actions that you have encountered so far --- executing Axiom commands, popping up new windows, providing parameters for other active areas, and replacing or changing the contents of the window. The most common action is to bring up some Hyperdoc text in the same or a different window. This lets us create links between pieces of text and images. A system with such capability is usually called a hypertext system. Hyperdoc is in fact much more.

Hyperdoc can read the hypertext information from standard text files. This means that you can create or change this information with

\beginscroll
\begin{page}{HTXIntroPage2}{How Hyperdoc does it}
{\centerline{{\tt \thispage}}}\newline
\end{page}

21.18 htxintropage2.ht

How Hyperdoc does it

⇒ “notitle” (HTXIntroPage3) 21.19 on page 2666

Hyperdoc can read the hypertext information from standard text files. This means that you can create or change this information with
any text editor. Once this information has been entered into the files, a special program, called `{bf htadd}`, scans these files and produces a database (another file called `{bf ht.db}`) of `{em objects}` encountered in the files. Hyperdoc consults this database when it first starts and so knows where it might find the definitions of these objects. You can maintain several such databases on different directories. You indicate which database you want Hyperdoc to consult by setting an `{em environment variable}` called `{bf HTPATH}`.

In general, hypertext must obviously use some kind of special (that is, non-textual) marks for all the extra functionality it provides. In Hyperdoc, these marks are some special characters --- special in the sense that they are not interpreted as ordinary displayable text. These characters, however, are part of the standard ASCII set. There is also a way to display these special characters as text.

The Hyperdoc special characters are:

\beginImportant
\noindent{em Special Characters}:
\tt{\table{{\$}{\}{\{}{\}}{\[}{\]}{\%}{\#}}}
\endImportant

Hyperdoc uses the special characters to distinguish between `{em text}` and `{em commands}` (by `{em text}`, we mean here anything displayable). The commands are instructions to Hyperdoc to treat some text in a particular way. Some commands define special Hyperdoc objects. The most important objects are `{em pages}`, `{em patches}`, and `{em macros}`.

A `{em page}` is a description of the contents of a Hyperdoc window. A `{em patch}` is a portion of a page.

A `{em macro}` is a user-defined new Hyperdoc command.

Some commands allow special text `{em formatting}` and others associate some text with an action.

In order to display anything at all in `{bf HyperName}`, you must define a `{em page}`. The next section explains how to define a `{em page}` and put some simple text into it.
21.19  htxintropage3.ht

A simple text page

⇒ “notitle” (HTXLinkPage6) 21.26 on page 2693
⇒ “notitle” (HTXTryPage) 21.29 on page 2700
⇒ “notitle” (HTXFormatTopPage) 21.16 on page 2662
— htxintropage3.ht —

\begin{page}{HTXIntroPage3}{A simple text page}
{\centerline{\fbox{\tt \thispage}}}\newline
\begin{scroll}

A page is defined by a \em group\ command. Group commands are used to
delimit a group, that is, to declare where a group starts and where it
ends. The proper syntax for a page definition is as follows:
\beginImportant
{\tt \begin\{page\}\{{\it name}\}\{{\it a title}\}}
\newline
\newline
\newline
\newline
{\tt \end\{page\}}
\beginImportant

Note the use of the special characters {\tt \}, {\tt \{} and {\tt \}}. The {\tt \} (backslash) character introduces a command, in this
case, {\tt begin}. The {\tt \{ \}} (braces) delimit the \em parameters\ to the command. The first parameter (the word {\tt page})
specifies this as a page definition command.

The second parameter can be any single unbroken word consisting of
alphanumeric characters only, and specifies the name of the page by
which it can be referred to by other commands. You should choose this
internal name with care so as to avoid potential conflict with page
names that are defined by the Axiom system. This caveat only applies
in the case where you have started Hyperdoc with the Axiom database
--- see \downlink{later on}{HTXLinkPage6}. It is suggested that the
page names you define start with the letters {\tt UX} (standing for
{\tt User e\{\tt X\}ensions). You can have a look at the Axiom system
database file \centerline{\bf \env{AXIOM}/doc/ht.db} which contains the names of all pages, macros and patches used by
Axiom.
The third parameter specifies a title for the page. The title of a page is the area at the very top of the window, between the buttons. Virtually anything that can be put in the main page can also be put in the title. As an example, \emph{this} page’s declaration is like this:

\texttt{\begin{page}\{thispage\}\{A simple text page\}}

Everything you type between the \texttt{\begin{page}} command and the next \texttt{\end{page}} command will become the body of the page. It is an error to insert another \texttt{\begin{page}} between the two, that is, this group command cannot be nested.

There is another useful group command that should be mentioned here --- the \emph{scroll} command. It controls the portion of the page that will be scrollable. Hyperdoc will split a page in three sections: a \emph{header}, a \emph{scroll region} and a \emph{footer}. Hyperdoc will always try to keep the header and footer regions visible on the page; the header at the top and the footer at the bottom. The middle scroll region will be truncated and a scroll bar will be automatically provided if the window becomes too small for the whole contents of the page. Only one scroll region can be defined in a page and the correct syntax is as follows:

\begin{important}
\texttt{\begin{scroll}}
newline
newline
newline
\texttt{\end{scroll}}
\begin{important}

This group should be placed inside the relevant page group. The text between the \texttt{\begin{page}} and \texttt{\begin{scroll}} commands defines the header region, the text inside the scroll group defines the scroll region and the text between the \texttt{\end{scroll}} and \texttt{\end{page}} commands defines the footer region. It is important to keep the header and footer areas small. Use them to display information that might be needed at any time by the user. If you don’t define a scroll region in your page, you may find that a portion of the page is truncated.

You are now ready to experiment with a page of your own. If you just want to display some text on a page, you don’t need any other Hyperdoc commands. Just make sure that the text you type for the title, header, scroll and footer regions does not contain (for the moment) any of the Hyperdoc special characters.
Hyperdoc is both a way of presenting information and a customisable front-end. Axiom uses it for its own purpose as a front-end and documentation system. Hyperdoc has special facilities that allow it to interact very closely with Axiom. The \Browse{} facility, the Basic Commands section and the ability to execute Axiom commands by clicking on Hyperdoc text are witness to this.

These pages will show you the features of Hyperdoc that might make it appropriate for your own use in, for example, providing documentation for Axiom code that you write or some other purpose.

It is recommended that you get familiar with the {\em use} of Hyperdoc before proceeding.
21.21 Linking to a named page

\begin{page}{HTXLinkPage1}{Linking to a named page}
\centerline{\fbox{\tt \thispage}}
\begin{scroll}
In Hyperdoc, hypertext links are specified by different flavors of the \tt \link command. These commands take two arguments. One argument specifies the active area, that is, the \textit{trigger} of the link. The second argument specifies the \textit{target} of the link, that is, a page. The trigger can be quite arbitrary Hyperdoc text and can include images or whole paragraphs. The trigger text will be formatted in the normal fashion but its default font will be the font specified by the ActiveFont resource.

The simplest kind of Hyperdoc link is a link to a named page. Clicking on the trigger will cause the named page to appear in a Hyperdoc window.

There are three flavors for such a link.
\begin{items}
\item \tt \windowlink{{\it trigger}}{{\it page name}}
This link command, when activated, will create a new window for the named page.
\item \tt \downlink{{\it trigger}}{{\it page name}}
This link command, when activated, will cause the
current page to be replaced by the target page
in the same Hyperdoc window.
A \centerline{\UpBitmap{}} button will automatically be placed
on the new page allowing you to get back to the page
containing the \{tt \downlink\} command.
If the current page has a \centerline{\ReturnBitmap{}} button then
the target page will also carry it. The associated
target page of that button will be the same as it is
in the current page.
\item \menuitemstyle{\tt \memolink\{{\it trigger}\}\{{\it page name}\}}
  \newline This link command is similar to the \{tt \downlink\} command.
  In addition, it will cause a \centerline{\ReturnBitmap{}} button
  to be included in
  the target page and all pages \{tt \downlink\}ed from it.
  This button will act as a
direct link to the page containing the \{tt \memolink\} command allowing
  a short-cut to be taken.
\end{items}

\beginImportant
\begin{paste}{HTXLinkPage1xPaste1}{HTXLinkPage1xPatch1}
\pastebutton{HTXLinkPage1xPaste1}{Interpret}
\newline
{\tt \windowlink\{windowlink to Actions menu\}\{HTXLinkTopPage\}\newline}
{\tt \downlink\{downlink to Actions menu\}\{HTXLinkTopPage\}\newline}
{\tt \memolink\{memolink to Actions menu\}\{HTXLinkTopPage\}}
\end{paste}
\endImportant

There is a fourth button that can appear at the top of the page
next to the \centerline{\ExitBitmap{}} button.
Its purpose is to provide access to a particular \{tt help page\}
associated with the current page.
That is the \centerline{\HelpBitmap{}} button. The command to use is
\centerline{\{tt \helppage\{{\it help page name}\}}}.
The \{tt \helppage\} command {\it must} be placed
just before the \{tt \end\{page\}\} command.
For instance, to get a help button on this page
the following command is used.
\centerline{\{tt \{\helppage\{TestHelpPage\}\}}}.
Clicking on the help button at the top
will display the \{tt TestHelpPage\} page in a new window.

— htxlinkpage2.ht —

\begin{page}{HTXLinkPage2}{Standard Pages}
\centerline{\fbox{{\tt \thispage}}} \newline
\begin{scroll}
You have reached this page after performing a series of mouse clicks on Hyperdoc active areas. Each time, a {\tt \link} command was activated. Well, how does it all start? The answer is that Hyperdoc always puts up a particular page called {\tt RootPage} when it starts up. If this page is not found in the database, Hyperdoc will immediately exit. It is, of course, desirable that the {\tt RootPage} contains links to other pages! It is possible to override Axiom’s choice of {\tt RootPage} and provide your own to Hyperdoc. This is done in the same way as
you would override any Axiom-defined page and is discussed in \downlink{How to use your pages with Hyperdoc}{HTXLinkPage6}.

You may have noticed that Hyperdoc uses some pages when certain events occur. There is a page that is put up, for instance, whenever Hyperdoc cannot connect to Axiom. Another page is put up whenever there is a formatting error and yet another when a request for an unknown page is made. Finally, there is a page that prompts for confirmation when you press the exit button on the initial page.

These pages have standard names and must be provided in the Hyperdoc page database. They are already defined in the Axiom system Hyperdoc page database so that you do not have to define them yourself.

Here are the pages required by Hyperdoc. You can click on any of these to see their contents. Click on their exit buttons when you are finished.

\beginImportant
\begin{paste}{HTXLinkPage2xPaste1}{HTXLinkPage2xPatch1}
\pastebutton{HTXLinkPage2xPaste1}{Interpret}
\newline
{\tt \table{}
{\tt \{windowlink\{SpadNotConnectedPage\}\{SpadNotConnectedPage\}\}}

{\tt \{windowlink\{UnknownPage\}\{UnknownPage\}\}}
newline
{\tt \{windowlink\{ErrorPage\}\{ErrorPage\}\}}
newline
{\tt \{windowlink\{ProtectedQuitPage\}\{ProtectedQuitPage\}\}}
newline
{\tt }\newline
\end{paste}
\endImportant

In addition, Hyperdoc uses certain bitmaps for its buttons. They are also provided in the Axiom system bitmap directory and Hyperdoc knows where to find them.

The bitmap files required by Hyperdoc are the following.
\newline
\tab{7}{\it exit.bitmap}\tab{22} = \tab{25}{\ExitBitmap{}}\newline
\tab{7}{\it help2.bitmap}\tab{22} = \tab{25}{\HelpBitmap{}}\newline
\tab{7}{\it up3.bitmap}\tab{22} = \tab{25}{\UpBitmap{}}\newline
\tab{7}{\it return3.bitmap}\tab{22} = \tab{25}{\ReturnBitmap{}}\newline
These files must exist in your current directory if the {tt AXIOM} environment variable is not set. If it is, then Hyperdoc will assume that it points to the Axiom system directory and will look for these files in \{bfAXIOM/doc/bitmaps\}.

\end{patch}
Active Axiom commands

The first command to learn is

\begin{flushleft}
\verb+a%%command% \free\%var1 \var2 \ldots\bound\%var\%
\end{flushleft}

The \verb+\free+ and \verb+\bound+ directives are optional. We will come to them in a minute. The \verb+\it command+ above is the text of the Axiom command. Only single line commands are allowed here. This text will be displayed in the reserved AxiomFont logical
font. The area of the text will be active and clicking on it will attempt to send the command to Axiom for evaluation.

A new Axiom interpreter window (and Axiom frame) will be created if this was the first Axiom command activated in the current page. If not, the command will be sent to the already opened Axiom interpreter window for the current page.

Note that it *is* necessary to escape special Hyperdoc characters with the `\` backslash character. The exceptions are the characters `{tt \[\]}; they do not need to be escaped in this context.

```
\beginImportant
\begin{paste}{HTXLinkPage3xPaste1}{HTXLinkPage3xPatch1}
\pastebutton{HTXLinkPage3xPaste1}{Interpret}
\newline
{\tt \axiomcommand\{ l:=brace[1,2,3] ; length:=\# l ; m:=[1,2]\}}
\end{paste}
\endImportant
```

The optional `{tt \free\{\}}` and `{tt \bound\{\}}` directives provide dependency control. The reader of a Hyperdoc page is not forced to click on the commands in the order in which they appear on the page. If the correct `{tt \free\{\}}` and `{tt \bound\{\}}` specifications are made, clicking on a command will result in execution of all those other commands that should be executed before it. This will *only* happen the first time the command is clicked.

So, how are the dependencies specified? The arguments of the `{tt \free\{\}}` directive must be space-separated words (labels). The argument of `{tt \bound\{\}}` must be a single (unique for the page) label. Each label in the `{tt \free\{\}}` list must exist as an argument to one (and only one) `{tt \bound\{\}}` directive somewhere in the current page. When the command is activated, Hyperdoc will look in the `{tt \free\{\}}` list and check each label. For each label, it will find the command that specifies that label in its `{tt \bound\{\}}` directive and execute it if it has not been already executed. The order of labels in the `{tt \free\{\}}` directive list is respected. Hyperdoc will follow all dependency links recursively.

Here is an example. Clicking on the third command will automatically execute all of them in the correct sequence.

Note that in this case the order of labels in the last line is immaterial since `{tt v2}` explicitly depends on `{tt v1}`.

```
\beginImportant
```
The second command deals with multi-line Axiom code. This is the command to use for execution of an Axiom \texttt{pile} command. It is a \texttt{group} command. The proper syntax for it is as follows:

\begin{spadsrc}
\begin{\free\{\texttt{var1 var2} ...\}\\bound\{\texttt{var}\}\}
\newline.
\newline.
\newline\end{spadsrc}

Again, the \texttt{\free} and \texttt{\bound} directives are optional. If they are specified (in exactly the same way as \texttt{\axiomcommand}), they must be enclosed in square brackets \texttt{[]}.

The lines between the \texttt{\begin} and \texttt{\end} contain the Axiom statements. Indentation will be respected. Hyperdoc will actually save this part in a temporary file and instruct Axiom to read the file with the \texttt{\read} system command.

Here is an example. The execution of the following fragment is dependent on the \texttt{v3} label. Make sure that previous commands are active (and hence the label \texttt{v3} is "visible") before trying to execute it. If the label \texttt{v3} is not seen in the page, Hyperdoc will print an error message on standard output and ignore the dependency.
{\tt \begin{spadsrc} \ [\ \free\{v3\}\ \bound\{v4\}]\newline
{\tt f\ x\ ==}\newline
{\tt \ \ \ x+c}\newline
{\tt f\ \ 3}\newline
{\tt \end\{spadsrc\}}
\end{paste}
\endImportant

There is, in fact, more that one can do with Axiom commands. In pages elsewhere in the system, Axiom commands appear next to button like this \MenuDotBitmap{}. Clicking on this button, one can see the output for that command. The output has been pre-computed and is also stored in Hyperdoc files. This is done using {\it patch} and {\it paste}. It is the same mechanism that is used to alternatively display Hyperdoc source and interpreted result in this and other pages. It is explained \downlink{later on}{HTXAdvPage5}.

Linking to Lisp

The first is to cause the evaluation of a \it{Lisp} form and ignore (as far as Hyperdoc is concerned) its value. The evaluation of the function might have an effect however on your Axiom session.

The command for this is
\begin{verbatim}
\lispcommand{Definition}{(defun HTXTESTFUNCTION ()}
\lispcommand{Execution}{(HTXTESTFUNCTION) }
\end{verbatim}

Here is an example. We will first define a \it{Lisp} function and then execute it. Notice that the Hyperdoc special characters must be escaped (this is on top of \it{Lisp} escaping conventions).

\begin{verbatim}
(defun HTXTESTFUNCTION ()
 (print "Hello from HyperDoc\\\\\\\\\\\\\\\\\\\\\\\\\\\"")
)
(HTXTESTFUNCTION)
\end{verbatim}
Your command will be executed as soon as Axiom completes any computation it might be carrying out.

\%\axiomcommand{lisp (defun f () (pprint "hello"))}
%\lispcommand{f}{(|f|)}

The second thing you can do is quite powerful. It allows you to delegate to a \textit{Lisp} function the \textit{dynamic} creation of a page. This is used in \texttt{Browse{}} to present the Axiom Library in a hypertext form. The command to use is a lot like the \texttt{link} commands you encountered earlier and comes in three flavors.
\centerline{\texttt{\lispwindowlink{\it trigger}{\it Lisp form}}}
\centerline{\texttt{\lispdownlink{\it trigger}{\it Lisp form}}}
\centerline{\texttt{\lispmemolink{\it trigger}{\it Lisp form}}}

The difference between the three versions is the same as before. When such a link is activated, Hyperdoc issues the \textit{Lisp form} to Axiom and waits for a full page definition. An important point to note is that Hyperdoc does not use the value of the \textit{Lisp form} but, instead, it depends on its side-effects. What \textit{must} happen during evaluation of the form is enough evaluations of a special \textit{Lisp} function called \texttt{issueHT} to define a page. The argument of \texttt{issueHT} is a string containing Hyperdoc text. Perhaps an example will clarify matters.

First we will define a \textit{Lisp} function that accepts a string argument and calls \texttt{issueHT} a few times. The strings that are passed to \texttt{issueHT} construct a Hyperdoc page that would just contain our original argument centered roughly on the page. Then we write the \texttt{\lisplink} with a call to the function. Finally, we execute a \textit{Lisp} command that just pretty--prints the function’s definition.

\beginImportant
\begin{paste}{HTXLinkPage4xPaste2}{HTXLinkPage4xPatch2}
\begin{verbatim}
(defun HTXTESTPAGE (X) (|issueHT| "\\begin\{page\}{LispTestPage}{Lisp Test Page}\\vspace{150}\\centerline{" (|issueHT| X) (|issueHT|} \\
\\end{page}" ) ) \\
\end{verbatim}

The definition of \tt HTXTESTPAGE would have been written in \tt Lisp as follows.
\begin{verbatim}
(defun HTXTESTPAGE (X)
  (|issueHT|
    "\\begin\{page\}{LispTestPage}{Lisp Test Page}\\vspace{200}\\centerline{")
    (|issueHT| X)
    (|issueHT| "} \end{page}")
\end{verbatim}

You should not execute \tt HTXTESTPAGE in the \tt Lisp environment manually. It is meant to be executed \tt only in response to a Hyperdoc request.

Can you pop-up a named page from \tt Lisp regardless of user action? Yes --- use \tt Lisp function \tt\bf linkToHTPage with the page name as a string argument. Click on the \tt axiomcommand below. Then, in your Axiom session, you can repeat it if you like.
You can also pop-up a \it{dynamic} page regardless of user action.
To do this, make sure you evaluate the \it{Lisp form} \\
\textbf{(\texttt{startHTPage} 50)} before using \textbf{issueHT}.

The example below requires the \texttt{HTXTESTPAGE} function to be defined in \it{Lisp} so you should make sure you have executed the command above that defines it.

\beginImportant
\begin{paste}{HTXLinkPage4xPatch4}
\pastebutton{HTXLinkPage4xPatch4}{Interpret}
\end{paste}
\endImportant

Now, the most important use of this facility so far has been in the \Browse{} and Basic Commands components of Hyperdoc. Instead of giving you details of the various \Browse{} \it{Lisp} functions, a few macros are defined in \centerline{\texttt{\$AXIOM/doc/util.ht}}

The most important defined macros are

\beginImportant
\begin{table}
{ \tt \axiomType\{Expression Integer\}\newline } \tt \axiomType\{Expression\}\newline \tt \axiomType\{EXPR\}\newline
\end{table}
\endImportant

Here are some examples of their use.

\beginImportant
\begin{paste}{HTXLinkPage4xPatch5}
\pastebutton{HTXLinkPage4xPatch5}{Interpret}
\end{paste}
\endImportant
The macro \texttt{\axiomType} brings up the \texttt{Browse} constructor page for the constructor specified. You can specify a full name, or an abbreviation or just the top level name. The macro \texttt{\axiomOp} brings up a list of operations matching the argument. The macro \texttt{\axiomOpFrom} shows documentation about the specified operation whose origin is constructor. No wildcard in the operation name or type abbreviation is allowed here. You should also specify just the top level type.

The patch HTXLinkPage4xPatch1 contains the following code:

```lisp
(defun HTXTESTFUNCTION ()
  (print "Hello from HyperDoc \"\% \{ \}\"))
```

This code prints a message indicating it was run from HyperDoc.

Let us conclude the tour of Hyperdoc actions that can be triggered with a click of a button with two more facilities. These are

\begin{table}{|c|c|}
\hline
{\tt \unixcommand\{{\it trigger text}\}\{{\it unix command}\}} & {\tt \unixlink\{{\it trigger text}\}\{{\it unix command}\}} \\
\hline
\end{table}

The first one, {\tt \unixcommand}, is very much like {\tt \axiomcommand} and {\tt \lispcommand}. The trigger text becomes an active area. Clicking on it will force Hyperdoc to pass the second argument to the system as a shell command to be executed. The shell used is {\bf /bin/sh}. Hyperdoc ignores the output of the command.

\begin{important}
\begin{paste}{HTXLinkPage5xPaste1}{HTXLinkPage5xPatch1}
\pastebutton{HTXLinkPage5xPaste1}{Interpret}
\end{important}

\begin{important}
\begin{paste}{HTXLinkPage5xPaste1}{HTXLinkPage5xPatch1}
\pastebutton{HTXLinkPage5xPaste1}{Interpret}
\end{important}

The {\tt \unixlink} command delegates to another program the creation of a dynamic page. When the trigger text is activated, Hyperdoc will invoke the command specified in the second argument. It will then start reading the {\it standard output} of the command until a complete page has been received. It is important that a single page and nothing more is written by the command. This command is essentially a {\tt \downlink}, i.e. the new page replaces the current page in the window. There aren’t any other flavours of {\tt \unixlink}.
A trivial example is to use \textbf{cat} on a Hyperdoc file known to contain just one page.

\begin{quote}
\texttt{\unixlink\{Some file\}}
\texttt{\{cat\ \\emph{env\{AXIOM\}/doc/HTXplay.ht\}}
\end{quote}

Two things to notice in the second argument of \texttt{\unixlink}: You must use a \texttt{\\ } to preserve the spacing in the command. Also, the \texttt{\emph{env}} command allows you to use an environment variable in Hyperdoc text.

With a little ingenuity (and maybe some shell and \texttt{\textbf{awk}} scripts !), one can use these facilities to create, say, a point-and-click directory viewer which allows you to edit a file by clicking on its name.

\begin{quote}
\unixcommand{List \$HOME directory}{\ls \$HOME}
\end{quote}
HTXLinkPage5xPatch1A patch

{\tt \unixlink{Some file}}
{\tt \{cat \ \%env\{AXIOM\}/doc/HTXplay.ht\}}
\end{paste}
\end{patch}
```
How to use your pages with Hyperdoc

Let us say that you have written a few Hyperdoc pages and you would like to incorporate them in the system. Here is what you should do.

Put all your files in some directory and make sure that they all have the \{bf .ht\} extension.

You will need a way of "hooking" into a system--defined Hyperdoc page. The proper way to do this is to use the \{tt \localinfo\} macro. The Axiom system Hyperdoc page database includes, as it should, a \{tt RootPage\}. This is the page that first comes up when you start Hyperdoc. This page contains a line like this.

This macro is defined in \centerline{ \{bf \env{AXIOM}/doc/util.ht\}}
to be (see \downlink{Macros}{HTXAdvPage3} to learn how to define macros):

which is an empty definition (the second argument of \{tt \newcommand\}). The idea then is that you \{tt override\} this definition of the macro with your own. To do that, include a definition like the following in one (possibly the one that contains your top--level page) of your files. You can
put this definition in its own file if you like.
\beginImportant
\tt
\newcommand{\localinfo}
\{{\it active text}\}}
\tt
\{{\it page name}\} \tab\{16\}{{\it short description}}\}
\endImportant

If you have a look at the initial Hyperdoc page, you will probably be able to decipher what this does. The macro {\tt \menuwindowlink} is defined (again in {\bf util.ht}) and is responsible for putting the little square to the left of the active area. Specify a word or two for {\it active text}. That will become the trigger of the {\tt \link}. Specify the page name of your top--level page in {\it page name}. Finally, you can give a comment about the topic under {\it short description}. That will appear to the right of the {\it active text}.

The next thing you need to do is to create a {\it local database} for your files. You will use the {\bf \env{AXIOM}/bin/htadd} program. This program will create an {\bf ht.db} file that summarises your definitions and acts as an index. Let us present an example of its use. Suppose you have two files {\bf user1.ht} and {\bf user2.ht} in directory {\bf /u/sugar/Hyperdoc}. You should create the {\bf ht.db} in that same directory. To create the {\bf ht.db} file you issue to the unix shell:
\beginImportant
\tt
htadd -f /u/sugar/Hyperdoc
/u/sugar/Hyperdoc/user1.ht /u/sugar/Hyperdoc/user2.ht
\centerline{or ,if you are already in /u/sugar/Hyperdoc}
\{\tt htadd -l ./user1.ht ./user2.ht\}
\endImportant

The options and conventions for {\bf htadd} will be explained below. To start Hyperdoc with your own pages, you now need to tell it where to search for {\bf ht.db} files and Hyperdoc {\bf .ht} files. To do this, define the shell environment variable {\bf HTPATH}. The value should be a colon {tt ':'} separated list of directory full pathnames. The order of the directories is respected with earlier entries overriding later ones. Since we want all the Axiom pages but need to override the {tt /localinfo} macro, we should use the value
\tt
\{\bf $PATH$ /u/sugar/Hyperdoc:\env{AXIOM}/doc\}
\tt
The way that you define environment variables depends on the shell you are using. In the {\bf /bin/csh}, it would be
\beginImportant
\tt
setenv HTPATH /u/sugar/Hyperdoc:\env{AXIOM}/doc\{hypertex\}/pages}
\endImportant
Important

Options for `{bf htadd}`

Important

Where does Hyperdoc look for files

---

**HTXLinkPage6xPatch1 patch**

--- htxlinkpage6.ht ---

```
{	t htadd - create or modify a Hyperdoc database}
\vspace{}
\newline
Syntax:

{	t htadd [ -l | -s | -f \ }\{\it path}\{\tt ]
[ -d | -n ] \ }\{\it filename ...\}
CHAPTER 21. HYPERTEX LANGUAGE PAGES

Options:

- \{-l\} build \{bf ht.db\} database in current working directory. This is the default behaviour if no \{-l\}, \{-s\} or \{-f\} is specified.

- \{-s\} build \{bf ht.db\} database in \{it system\} directory. The system directory is built as follows. If the \{tt AXIOM\} variable is defined, the \{bf \$AXIOM/doc\} directory is used. If \{tt AXIOM\} is not defined, the \{bf /usr/local/axiom/doc\} directory is used.

- \{-f\ \{it path\}\} build \{bf ht.db\} database in specified \{it path\}.

- \{-d\} delete the entries in the specified files from \{bf ht.db\}.

- \{-n\} delete \{bf ht.db\} and create a new one using only the files specified.

If none of \{-n\} and \{-d\} is specified, the \{bf ht.db\} is updated with the entries in the file specified.

Filename interpretation:

A full pathname (i.e. anything that has a \{tt '/'\} in it) will be taken to be a completely specified file. Otherwise, the following interpretation will occur:

If the \{tt HTPATH\} variable is defined, the directories specified in it will be tried in order. If \{tt HTPATH\} is not defined, then, if \{tt AXIOM\} is defined, the \{bf \$AXIOM/doc\} will be tried, else the file will be deemed missing and \{bf htadd\} will fail.
The Hyperdoc program is \begin{centerline}{\bf \env{AXIOM}/lib/hypertex}\end{centerline} If \tt{AXIOM} is defined and \tt{HTPATH} is not (this is the case when Axiom starts Hyperdoc) Hyperdoc will look in \begin{centerline}{\bf \env{AXIOM}/doc}\end{centerline} for the \tt{ht.db} file and all Hyperdoc pages. If \tt{HTPATH} is defined, it is assumed that it alone points to the directories to be searched (the above default will NOT be searched unless explicitly specified in \tt{HTPATH}). For each directory in \tt{HTPATH}, the \tt{ht.db} file, if there, will be read. Each file listed in \tt{ht.db} will then be searched for in the complete sequence of directories in \tt{HTPATH}. Note that the \tt{ht.db} does not keep full pathnames of files. If a \tt{page}, \tt{macro} or \tt{patch} (specified in some \tt{ht.db}) happens to be (in a file) in more than one of the directories specified in \tt{HTPATH}, Hyperdoc will print a warning and explain which version in which file is ignored. Generally, earlier directories in \tt{HTPATH} are preferred over later ones.

Try out Hyperdoc

--- htxtrypage.ht ---

\begin{page}{HTXTryPage}{Try out Hyperdoc}
\centerline{\fbox{{\tt \thispage}}}
\newline
This page allows you to quickly experiment with Hyperdoc. It is a good idea to keep it handy as you learn about various commands.
\beginscroll

We are going to use here the Hyperdoc facilities that allow us to communicate with external programs and files. For more information see \downlink{later on}{HTXLinkPage5}.
\begin{item}{menuitemstyle}
In order to use the buttons at the bottom of this page, you must first specify a name for the file you are going to use to hold Hyperdoc commands. Edit the input area below to change the name of the file.
\item{menuitemstyle}
If the file you specified does not yet exist, click on the \{\bf Initialize\} button below. This action will fill the file with the minimum of Hyperdoc commands necessary to define a page.
\item{menuitemstyle}
If you want to edit the file, just click on the \{\bf Edit\} button. This action will pop up a window, and invoke the \{\it vi\}
editor on the file. Alternatively, use an editor of your choice."
\item \menuitemstyle{
Once you have finished making the changes to the file, update it and click on the \bf{Link} button. Hyperdoc will then read the file, interpret it as a new page, and display the page on this window. If you change the file and want to display it again, just get back to this page and click on \bf{Link} again. }
\endmenu
\endscroll
\beginmenu
{\it Filename: }{\inputstring{filename}{40}{\env{HOME}/HTXplay.ht}}
\menuunixcommand{Initialize}{cp \space{1}\env{AXIOM}/doc/HTXplay.ht \stringvalue{filename}} \tab{20} Get a fresh copy from the system.
\menuunixcommand{Edit}{xterm -T \"\stringvalue{filename}\" -e vi \stringvalue{filename}} \tab{20} Edit the file.
\menuunixwindow{Link}{cat \space{1}\stringvalue{filename}}} \tab{20} Link to the page defined in the file.
\endmenu
{\it Important : The file must contain one and only one page definition and must not contain any macro or patch definitions.}
\end{page}

NAG Library Routines

22.1 nagaux.ht

NAG On-line Documentation

— nagaux.ht —

\begin{page}\{manpageXXonline\}\{NAG On-line Documentation\}
\beginscroll
\begin{verbatim}

DOC INTRO(3NAG)  Foundation Library (12/10/92)  DOC INTRO(3NAG)

Introduction to NAG On-Line Documentation

The on-line documentation for the NAG Foundation Library has been
generated automatically from the same base material used to
create the printed Reference Manual. To make the documentation
readable on the widest range of machines, only the basic set of
ascii characters has been used.

Certain mathematical symbols have been constructed using plain
ascii characters:

integral signs  \( / \)
\[ | \]

2703
summation signs  --
   >
   --

square root signs  ----
   /
   \/

Large brackets are constructed using vertical stacks of the equivalent ascii character:

```
( ) [ ] { } |
( ) [ ] { } |
( ) [ ] { } |
```

Fractions are represented as:

```
a
---
x+1
```

Greek letters are represented by their names enclosed in round brackets:

```
(alpha)  (beta)  (gamma)  ....
(Alpha)  (Beta)  (Gamma)  ....
```

Some characters are accented using:

```
^ ~ X X X
```

Other mathematical symbols are represented as follows:

```
*      times
<=     left-right arrow
<-     left arrow
~      similar to
```
22.1. NAGAUX.HT

NAG Documentation: summary

— nagaux.ht —

The NAG Foundation Library contains three categories of routines which can be called by users. They are listed separately in the
three sections below.

Fully Documented Routines
254 routines, for each of which an individual routine document is provided. These are regarded as the primary contents of the Foundation Library.

Fundamental Support Routines
83 comparatively simple routines which are documented in compact form in the relevant Chapter Introductions (F06, X01, X02).

Routines from the NAG Fortran Library
An additional 167 routines from the NAG Fortran Library, which are used as auxiliaries in the Foundation Library. They are not documented in this publication, but can be called if you are already familiar with their use in the Fortran Library. Only their names are given here.

Note: all the routines in the above categories have names ending in 'F'. Occasionally this publication may refer to routines whose names end in some other letter (e.g. 'Z', 'Y', 'X'). These are auxiliary routines whose names may be passed as parameters to a Foundation Library routine; you only need to know their names, not how to call them directly.

Fully Documented Routines

The Foundation Library contains 254 user-callable routines, for each of which an individual routine document is provided, in the following chapters:

C02 -- Zeros of Polynomials

C02AFF All zeros of complex polynomial, modified Laguerre method

C02AGF All zeros of real polynomial, modified Laguerre method

C05 -- Roots of One or More Transcendental Equations

C05ADF Zero of continuous function in given interval, Bus and Dekker algorithm

C05NBF Solution of system of nonlinear equations using function values only

C05PBF Solution of system of nonlinear equations using 1st derivatives
22.1. NAGAUX.HT

C05ZAF  Check user’s routine for calculating 1st derivatives

C06   --  Summation of Series

C06EAF  Single 1-D real discrete Fourier transform, no extra workspace

C06EBF  Single 1-D Hermitian discrete Fourier transform, no extra workspace

C06ECF  Single 1-D complex discrete Fourier transform, no extra workspace

C06EKF  Circular convolution or correlation of two real vectors, no extra workspace

C06FPF  Multiple 1-D real discrete Fourier transforms

C06FQF  Multiple 1-D Hermitian discrete Fourier transforms

C06FRF  Multiple 1-D complex discrete Fourier transforms

C06FUF  2-D complex discrete Fourier transform

C06GBF  Complex conjugate of Hermitian sequence

C06GCF  Complex conjugate of complex sequence

C06GQF  Complex conjugate of multiple Hermitian sequences

C06GSF  Convert Hermitian sequences to general complex sequences

D01   --  Quadrature

D01AJF  1-D quadrature, adaptive, finite interval, strategy due to Piessens and de Doncker, allowing for badly-behaved integrands

D01AKF  1-D quadrature, adaptive, finite interval, method suitable for oscillating functions

D01ALF  1-D quadrature, adaptive, finite interval, allowing for singularities at user-specified break-points

D01AMF  1-D quadrature, adaptive, infinite or semi-infinite interval

D01ANF  1-D quadrature, adaptive, finite interval, weight function \( \cos((\omega)x) \) or \( \sin((\omega)x) \)

22.1. NAGAUX.HT

D03 -- Partial Differential Equations

D03EDF Elliptic PDE, solution of finite difference equations by a multigrid technique

D03EEF Discretize a 2nd order elliptic PDE on a rectangle

D03FAF Elliptic PDE, Helmholtz equation, 3-D Cartesian coordinates

E01 -- Interpolation

E01BAF Interpolating functions, cubic spline interpolant, one variable

E01BEF Interpolating functions, monotonicity-preserving, piecewise cubic Hermite, one variable

E01BFF Interpolated values, interpolant computed by E01BEF, function only, one variable

E01BGF Interpolated values, interpolant computed by E01BEF, function and 1st derivative, one variable

E01BHF Interpolated values, interpolant computed by E01BEF, definite integral, one variable

E01DAF Interpolating functions, fitting bicubic spline, data on rectangular grid

E01SAF Interpolating functions, method of Renka and Cline, two variables

E01SBF Interpolated values, evaluate interpolant computed by E01SAF, two variables

E01SEF Interpolating functions, modified Shepard's method, two variables

E01SFF Interpolated values, evaluate interpolant computed by E01SEF, two variables

E02 -- Curve and Surface Fitting

E02ADF Least-squares curve fit, by polynomials, arbitrary data points

E02AEF Evaluation of fitted polynomial in one variable from Chebyshev series form (simplified parameter list)
CHAPTER 22. NAG LIBRARY Routines

- E02AGF  Least-squares polynomial fit, values and derivatives may be constrained, arbitrary data points,
- E02AHF  Derivative of fitted polynomial in Chebyshev series form
- E02AJF  Integral of fitted polynomial in Chebyshev series form
- E02AKF  Evaluation of fitted polynomial in one variable, from Chebyshev series form
- E02BAF  Least-squares curve cubic spline fit (including interpolation)
- E02BBF  Evaluation of fitted cubic spline, function only
- E02BCF  Evaluation of fitted cubic spline, function and derivatives
- E02BDF  Evaluation of fitted cubic spline, definite integral
- E02BEF  Least-squares cubic spline curve fit, automatic knot placement
- E02DAF  Least-squares surface fit, bicubic splines
- E02DCF  Least-squares surface fit by bicubic splines with automatic knot placement, data on rectangular grid
- E02DDF  Least-squares surface fit by bicubic splines with automatic knot placement, scattered data
- E02DEF  Evaluation of a fitted bicubic spline at a vector of points
- E02DFF  Evaluation of a fitted bicubic spline at a mesh of points
- E02GAF  L_1-approximation by general linear function
- E02ZAF  Sort 2-D data into panels for fitting bicubic splines

E04 -- Minimizing or Maximizing a Function

- E04DGF  Unconstrained minimum, pre-conditioned conjugate gradient algorithm, function of several variables using 1st derivatives
- E04DJF  Read optional parameter values for E04DGF from external file
22.1. NAGAUX.HT

E04DKF  Supply optional parameter values to E04DGF

E04FDF  Unconstrained minimum of a sum of squares, combined Gauss-Newton and modified Newton algorithm using function values only

E04GCF  Unconstrained minimum of a sum of squares, combined Gauss-Newton and quasi-Newton algorithm, using 1st derivatives

E04JAF  Minimum, function of several variables, quasi-Newton algorithm, simple bounds, using function values only

E04MBF  Linear programming problem

E04NAF  Quadratic programming problem

E04UCF  Minimum, function of several variables, sequential QP method, nonlinear constraints, using function values and optionally 1st derivatives

E04UDF  Read optional parameter values for E04UCF from external file

E04UEF  Supply optional parameter values to E04UCF

E04YCF  Covariance matrix for nonlinear least-squares problem

F01 -- Matrix Factorizations

F01BRF  LU factorization of real sparse matrix

F01BSF  LU factorization of real sparse matrix with known sparsity pattern

F01MAF  LL factorization of real sparse symmetric positive-definite matrix

F01MCF  LDL factorization of real symmetric positive-definite variable-bandwidth matrix

F01QCF  QR factorization of real m by n matrix (m>=n)

F01QDF  Operations with orthogonal matrices, compute QB or QB after factorization by F01QCF

F01QEF  Operations with orthogonal matrices, form columns of Q
after factorization by F01QCF

F01RCF QR factorization of complex m by n matrix (m>=n)

H

F01RDF Operations with unitary matrices, compute QB or QB after factorization by F01RCF

F01REF Operations with unitary matrices, form columns of Q after factorization by F01RCF

F02 -- Eigenvalues and Eigenvectors

F02AAF All eigenvalues of real symmetric matrix

F02ABF All eigenvalues and eigenvectors of real symmetric matrix

F02ADF All eigenvalues of generalized real symmetric-definite eigenproblem

F02AEF All eigenvalues and eigenvectors of generalized real symmetric-definite eigenproblem

F02AFF All eigenvalues of real matrix

F02AGF All eigenvalues and eigenvectors of real matrix

F02AJF All eigenvalues of complex matrix

F02AKF All eigenvalues and eigenvectors of complex matrix

F02AWF All eigenvalues of complex Hermitian matrix

F02AXF All eigenvalues and eigenvectors of complex Hermitian matrix

F02BBF Selected eigenvalues and eigenvectors of real symmetric matrix

F02BJF All eigenvalues and optionally eigenvectors of generalized eigenproblem by QZ algorithm, real matrices

F02FJF Selected eigenvalues and eigenvectors of sparse symmetric eigenproblem

F02WEF SVD of real matrix

F02XEF SVD of complex matrix

F04 -- Simultaneous Linear Equations
F04ADF Approximate solution of complex simultaneous linear equations with multiple right-hand sides

F04ARF Approximate solution of real simultaneous linear equations, one right-hand side

F04ASF Accurate solution of real symmetric positive-definite simultaneous linear equations, one right-hand side

F04ATF Accurate solution of real simultaneous linear equations, one right-hand side

F04AXF Approximate solution of real sparse simultaneous linear equations (coefficient matrix already factorized by F01BRF or F01BSF)

F04FAF Approximate solution of real symmetric positive-definite tridiagonal simultaneous linear equations, one right-hand side

F04JGF Least-squares (if rank = n) or minimal least-squares (if rank < n) solution of m real equations in n unknowns, rank <= n, m >= n

F04MAF Real sparse symmetric positive-definite simultaneous linear equations (coefficient matrix already factorized)

F04MBF Real sparse symmetric simultaneous linear equations

F04MCF Approximate solution of real symmetric positive-definite variable-bandwidth simultaneous linear equations (coefficient matrix already factorized)

F04QAF Sparse linear least-squares problem, m real equations in n unknowns

F07 -- Linear Equations (LAPACK)

F07ADF (DGETRF) LU factorization of real m by n matrix

F07AEF (DGETRS) Solution of real system of linear equations, multiple right-hand sides, matrix already factorized by F07ADF

F07FDF (DPOTRF) Cholesky factorization of real symmetric positive-definite matrix

F07FEF (DPOTRS) Solution of real symmetric positive-definite system of linear equations, multiple right-hand sides,
matrix already factorized by F07FDF

G01 -- Simple Calculations on Statistical Data

G01AAF Mean, variance, skewness, kurtosis etc, one variable, from raw data

G01ADF Mean, variance, skewness, kurtosis etc, one variable, from frequency table

G01AEF Frequency table from raw data

G01AFF Two-way contingency table analysis, with (chi) /Fisher’s exact test

G01ALF Computes a five-point summary (median, hinges and extremes)

G01ARF Constructs a stem and leaf plot

G01EAF Computes probabilities for the standard Normal distribution

G01EBF Computes probabilities for Student’s t-distribution

G01EAF Computes probabilities for (chi) distribution

G01EDF Computes probabilities for F-distribution

G01EED Computes upper and lower tail probabilities and probability density function for the beta distribution

G01EFF Computes probabilities for the gamma distribution

G01FAF Computes deviates for the standard Normal distribution

G01FBF Computes deviates for Student’s t-distribution

G01FCF Computes deviates for the (chi) distribution

G01FDF Computes deviates for the F-distribution

G01FEF Computes deviates for the beta distribution

G01FFF Computes deviates for the gamma distribution

G01HAF Computes probabilities for the bivariate Normal
distribution

G02 -- Correlation and Regression Analysis

G02BNF Kendall/Spearman non-parametric rank correlation coefficients, no missing values, overwriting input data

G02BQF Kendall/Spearman non-parametric rank correlation coefficients, no missing values, preserving input data

G02BXF Computes (optionally weighted) correlation and covariance matrices

G02CAF Simple linear regression with constant term, no missing values

G02DAF Fits a general (multiple) linear regression model

G02DGF Fits a general linear regression model for new dependent variable

G02DNF Computes estimable function of a general linear regression model and its standard error

G02FAF Calculates standardized residuals and influence statistics

G02GBF Fits a generalized linear model with binomial errors

G02GCF Fits a generalized linear model with Poisson errors

G03 -- Multivariate Methods

G03AAF Performs principal component analysis

G03ADF Performs canonical correlation analysis

G03BAF Computes orthogonal rotations for loading matrix, generalized orthomax criterion

G05 -- Random Number Generators

G05CAF Pseudo-random double precision numbers, uniform distribution over (0,1)

G05CBF Initialise random number generating routines to give repeatable sequence

G05CCF Initialise random number generating routines to give non-repeatable sequence
G05CFF Save state of random number generating routines
G05CGF Restore state of random number generating routines
G05DDF Pseudo-random double precision numbers, Normal distribution
G05DFF Pseudo-random double precision numbers, Cauchy distribution
G05DPF Pseudo-random double precision numbers, Weibull distribution
G05DYF Pseudo-random integer from uniform distribution
G05DZF Pseudo-random logical (boolean) value
G05EAF Set up reference vector for multivariate Normal distribution
G05ECF Set up reference vector for generating pseudo-random integers, Poisson distribution
G05EDF Set up reference vector for generating pseudo-random integers, binomial distribution
G05EHF Pseudo-random permutation of an integer vector
G05EJF Pseudo-random sample from an integer vector
G05EJF Set up reference vector from supplied cumulative distribution function or probability distribution function
G05EFYF Pseudo-random integer from reference vector
G05EZF Pseudo-random multivariate Normal vector from reference vector
G05FAF Generates a vector of pseudo-random numbers from a uniform distribution
G05FBF Generates a vector of pseudo-random numbers from a (negative) exponential distribution
G05FDF Generates a vector of pseudo-random numbers from a Normal distribution
G05FEF Generates a vector of pseudo-random numbers from a beta
distribution
G05FFF Generates a vector of pseudo-random numbers from a gamma distribution
G05HDF Generates a realisation of a multivariate time series from a VARMA model

G08 -- Nonparametric Statistics
G08AAF Sign test on two paired samples
G08ACF Median test on two samples of unequal size
G08AEF Friedman two-way analysis of variance on k matched samples
G08AFF Kruskal-Wallis one-way analysis of variance on k samples of unequal size
G08AGF Performs the Wilcoxon one sample (matched pairs) signed rank test
G08AHF Performs the Mann-Whitney U test on two independent samples
G08AJF Computes the exact probabilities for the Mann-Whitney U statistic, no ties in pooled sample
G08AKF Computes the exact probabilities for the Mann-Whitney U statistic, ties in pooled sample

G08CGF Performs the (chi) goodness of fit test, for standard continuous distributions

G13 -- Time Series Analysis
G13AAF Univariate time series, seasonal and non-seasonal differencing
G13ABF Univariate time series, sample autocorrelation function
G13ACF Univariate time series, partial autocorrelations from autocorrelations
G13ADF Univariate time series, preliminary estimation, seasonal ARIMA model
G13AFF Univariate time series, estimation, seasonal ARIMA model
G13AGF Univariate time series, update state set for forecasting
G13AHF Univariate time series, forecasting from state set
G13AJF Univariate time series, state set and forecasts, from fully specified seasonal ARIMA model
G13ASF Univariate time series, diagnostic checking of residuals, following G13AFF
G13BAF Multivariate time series, filtering (pre-whitening) by an ARIMA model
G13BCF Multivariate time series, cross correlations
G13BDF Multivariate time series, preliminary estimation of transfer function model
G13BEF Multivariate time series, estimation of multi-input model
G13BJF Multivariate time series, state set and forecasts from fully specified multi-input model
G13CBF Univariate time series, smoothed sample spectrum using spectral smoothing by the trapezium frequency (Daniell) window
G13CDF Multivariate time series, smoothed sample cross spectrum using spectral smoothing by the trapezium frequency (Daniell) window

M01 -- Sorting
M01CAF Sort a vector, double precision numbers
M01DAF Rank a vector, double precision numbers
M01DEF Rank rows of a matrix, double precision numbers
M01DJF Rank columns of a matrix, double precision numbers
M01EAF Rearrange a vector according to given ranks, double precision numbers
M01ZAF Invert a permutation

S -- Approximations of Special Functions
S01EAF Complex exponential, e
S13AAF Exponential integral E (x)
S13ACF Cosine integral Ci(x)
S13ADF Sine integral Si(x)
S14AAF Gamma function
S14ABF Log Gamma function
S14BAF Incomplete gamma functions P(a,x) and Q(a,x)
S15ADF Complement of error function erfc x
S15AEF Error function erf x
S17ACF Bessel function Y (x)
S17ADF Bessel function Y (x)
S17AEF Bessel function J (x)
S17AFF Bessel function J (x)
S17AGF Airy function Ai(x)
S17AHF Airy function Bi(x)
S17AJF Airy function Ai'(x)
S17AKF Airy function Bi'(x)
S17DCF Bessel functions Y (z), real a>0, complex z,
(nu)+a
S17DEF Bessel functions J (z), real a>0, complex z,
(nu)+a
S17DGF Airy functions Ai(z) and Ai'(z), complex z
S17DHF Airy functions Bi(z) and Bi'(z), complex z
CHAPTER 22. NAG LIBRARY ROUTINES

S17DLF  Hankel functions $H_j^{(n)}(z)$, $j=1,2$, real $a \geq 0$, complex $z$,
         $(n)=0,1,2,...$

S18ACF  Modified Bessel function $K_0(x)$

S18ADF  Modified Bessel function $K_1(x)$

S18AEF  Modified Bessel function $I_0(x)$

S18AFF  Modified Bessel function $I_1(x)$

S18DCF  Modified Bessel functions $K_\nu(z)$, real $a \geq 0$, complex $z$,
         $(\nu)=0,1,2,...$

S18DEF  Modified Bessel functions $I_\nu(z)$, real $a \geq 0$, complex $z$,
         $(\nu)=0,1,2,...$

S19AAF  Kelvin function $\text{ber} \; x$

S19ABF  Kelvin function $\text{bei} \; x$

S19ACF  Kelvin function $\text{ker} \; x$

S19ADF  Kelvin function $\text{kei} \; x$

S20ACF  Fresnel integral $S(x)$

S20ADF  Fresnel integral $C(x)$

S21BAF  Degenerate symmetrised elliptic integral of 1st kind
         $R(x,y)$
         $C$

S21BBF  Symmetrised elliptic integral of 1st kind $R(x,y,z)$
         $F$

S21BCF  Symmetrised elliptic integral of 2nd kind $R(x,y,z)$
         $D$

S21BDF  Symmetrised elliptic integral of 3rd kind $R(x,y,z,r)$
         $J$
22.1. NAGAUX.HT

X04 -- Input/Output Utilities
X04AAF Return or set unit number for error messages
X04ABF Return or set unit number for advisory messages
X04CAF Print a real general matrix
X04DAF Print a complex general matrix

X05 -- Date and Time Utilities
X05AAF Return date and time as an array of integers
X05ABF Convert array of integers representing date and time to character string
X05ACF Compare two character strings representing date and time
X05BAF Return the CPU time

Fundamental Support Routines

The following fundamental support routines are provided and are documented in compact form in the relevant chapter introductory material:

F06 -- Linear Algebra Support Routines
F06AAF (DROTG) Generate real plane rotation
F06EAF (DDOT) Dot product of two real vectors
F06ECF (DAXPY) Add scalar times real vector to real vector
F06EDF (DSCAL) Multiply real vector by scalar
F06EFF (DCOPY) Copy real vector
F06EGF (DSWAP) Swap two real vectors
F06EJF (DNRM2) Compute Euclidean norm of real vector
F06EKF (DASUM) Sum the absolute values of real vector elements
F06EFF (DROT) Apply real plane rotation
CHAPTER 22. NAG LIBRARY ROUTINES

F06GAF (ZDOTU) Dot product of two complex vectors, unconjugated
F06GBF (ZDOTC) Dot product of two complex vectors, conjugated
F06GCF (ZAXPY) Add scalar times complex vector to complex vector
F06GDF (ZSCAL) Multiply complex vector by complex scalar
F06GFF (ZCOPY) Copy complex vector
F06GGF (ZSWAP) Swap two complex vectors
F06JDF (ZDSCAL) Multiply complex vector by real scalar
F06JJF (DZNRM2) Compute Euclidean norm of complex vector
F06JKF (DZASUM) Sum the absolute values of complex vector elements
F06JLF (IDAMAX) Index, real vector element with largest absolute value
F06JMF (IZAMAX) Index, complex vector element with largest absolute value
F06PAF (DGEMV) Matrix-vector product, real rectangular matrix
F06PBF (DGBMV) Matrix-vector product, real rectangular band matrix
F06PCF (DSYMV) Matrix-vector product, real symmetric matrix
F06PDF (DSBMV) Matrix-vector product, real symmetric band matrix
F06PEF (DSPMV) Matrix-vector product, real symmetric packed matrix
F06PFF (DTRMV) Matrix-vector product, real triangular matrix
F06PFF (DTBMV) Matrix-vector product, real triangular band matrix
F06PHF (DTPMV) Matrix-vector product, real triangular packed matrix
F06PJF (DTRSV) System of equations, real triangular matrix
F06PKF (DTBSV) System of equations, real triangular band matrix
F06PLF (DTPSV) System of equations, real triangular packed matrix
matrix

F06PMF (DGER) Rank-1 update, real rectangular matrix
F06PPF (DSYR) Rank-1 update, real symmetric matrix
F06PQF (DSPR) Rank-1 update, real symmetric packed matrix
F06PRF (DSYR2) Rank-2 update, real symmetric matrix
F06PSF (DSPR2) Rank-2 update, real symmetric packed matrix
F06SAF (ZGEMV) Matrix-vector product, complex rectangular matrix
F06SBF (ZGEMV) Matrix-vector product, complex rectangular band matrix
F06SCF (ZHEMV) Matrix-vector product, complex Hermitian matrix
F06SDF (ZHERMV) Matrix-vector product, complex Hermitian band matrix
F06SEF (ZHEMV) Matrix-vector product, complex Hermitian packed matrix
F06SFF (ZTRMV) Matrix-vector product, complex triangular matrix
F06SGF (ZTRMV) Matrix-vector product, complex triangular band matrix
F06SHF (ZTPMV) Matrix-vector product, complex triangular packed matrix
F06SIF (ZTRSV) System of equations, complex triangular matrix
F06SKF (ZTBSV) System of equations, complex triangular band matrix
F06SLF (ZTPSV) System of equations, complex triangular packed matrix
F06SMF (ZGERU) Rank-1 update, complex rectangular matrix, unconjugated vector
F06SNF (ZGERC) Rank-1 update, complex rectangular matrix, conjugated vector
F06SPF (ZHEMV) Rank-1 update, complex Hermitian matrix
F06SQF (ZHERC) Rank-1 update, complex Hermitian packed matrix
F06SRF (ZHER2) Rank-2 update, complex Hermitian matrix
F06SSF (ZHPR2) Rank-2 update, complex Hermitian packed matrix
F06YAF (DGEMM) Matrix-matrix product, two real rectangular matrices
F06YCF (DSYMM) Matrix-matrix product, one real symmetric matrix, one real rectangular matrix
F06YFF (DTRMM) Matrix-matrix product, one real triangular matrix, one real rectangular matrix
F06YJF (DTRSM) Solves a system of equations with multiple right-hand sides, real triangular coefficient matrix
F06YPF (DSYRK) Rank-k update of a real symmetric matrix
F06YRF (DSYR2K) Rank-2k update of a real symmetric matrix
F06ZAF (ZGEMM) Matrix-matrix product, two complex rectangular matrices
F06ZCF (ZHEMM) Matrix-matrix product, one complex Hermitian matrix, one complex rectangular matrix
F06ZFF (ZTRMM) Matrix-matrix product, one complex triangular matrix, one complex rectangular matrix
F06ZJF (ZTRSM) Solves system of equations with multiple right-hand sides, complex triangular coefficient matrix
F06ZPF (ZHERK) Rank-k update of a complex Hermitian matrix
F06ZRF (ZHER2K) Rank-2k update of a complex Hermitian matrix
F06ZTF (ZSYMM) Matrix-matrix product, one complex symmetric matrix, one complex rectangular matrix
F06ZUF (ZSYRK) Rank-k update of a complex symmetric matrix
F06ZWF (ZSYR2K) Rank-2k update of a complex symmetric matrix

X01 -- Mathematical Constants

X01AAF (pi)

X01ABF Euler’s constant, (gamma)
22.1. NAGAUX.HT

X02 -- Machine Constants
X02AHF Largest permissible argument for SIN and COS
X02AJF Machine precision
X02AKF Smallest positive model number
X02ALF Largest positive model number
X02AMF Safe range of floating-point arithmetic
X02ANF Safe range of complex floating-point arithmetic
X02BBF Largest representable integer
X02BEF Maximum number of decimal digits that can be represented
X02BHF Parameter of floating-point arithmetic model, b
X02BJF Parameter of floating-point arithmetic model, p
X02BKF Parameter of floating-point arithmetic model, \( e_{\min} \)
X02BLF Parameter of floating-point arithmetic model, \( e_{\max} \)
X02DJF Parameter of floating-point arithmetic model, ROUNDS

Routines from the NAG Fortran Library

A number of routines from the NAG Fortran Library are used in the Foundation Library as auxiliaries and are not documented here:

NAG Documentation: introduction

— nagaux.ht —

Introduction

Essential Introduction to the NAG Foundation Library

This document is essential reading for any prospective user of the Library.

This document appears in both the Handbook and the Reference Manual for the NAG Foundation Library, but with a different Section 3 to describe the different forms of routine documentation in the two publications.

1. The Library and its Documentation
CHAPTER 22. NAG LIBRARY ROUTINES

1.1. Structure of the Library

1.2. Structure of the Documentation

1.3. On-line Documentation

1.4. Implementations of the Library

1.5. Library Identification

1.6. Fortran Language Standards

2. Using the Library

2.1. General Advice

2.2. Programming Advice

2.3. Error handling and the Parameter IFAIL

2.4. Input/output in the Library

2.5. Auxiliary Routines

3.3. Specifications of Parameters

3.3.1. Classification of Parameters

3.3.2. Constraints and Suggested Values

3.3.3. Array Parameters

3.4. Implementation-dependent Information

3.5. Example Programs and Results

3.6. Summary for New Users

4. Relationship between the Foundation Library and other NAG Libraries

4.1. NAG Fortran Library
4.2. NAG Workstation Library

4.3. NAG C Library

5. Contact between Users and NAG

6. General Information about NAG

7. References

1. The Library and its Documentation

1.1. Structure of the Library

The NAG Foundation Library is a comprehensive collection of Fortran 77 routines for the solution of numerical and statistical problems. The word 'routine' is used to denote 'subroutine' or 'function'.

The Library is divided into chapters, each devoted to a branch of numerical analysis or statistics. Each chapter has a three-character name and a title, e.g.

D01 -- Quadrature

Exceptionally one chapter (S) has a one-character name. (The chapters and their names are based on the ACM modified SHARE classification index [1].)

All documented routines in the Library have six-character names, beginning with the characters of the chapter name, e.g.

D01AJF

Note that the second and third characters are digits, not letters; e.g. 0 is the digit zero, not the letter O. The last letter of each routine name is always 'F'.

1.2. Structure of the Documentation

There are two types of manual for the NAG Foundation Library: a Handbook and a Reference Manual.

The Handbook has the same chapter structure as the Library: each chapter of routines in the Library has a corresponding chapter (of the same name) in the Handbook. The chapters occur in alphanumeric order. General introductory documents and indexes are placed at the beginning of the Handbook.
Each chapter in the Handbook contains a Chapter Introduction, followed by concise summaries of the functionality and parameter specifications of each routine in the chapter. Exceptionally, in some chapters (F06, X01, X02) which contain simple support routines, there are no concise summaries: all the routines are described together in the Chapter Introduction.

The Reference Manual provides complete reference documentation for the NAG Foundation Library. In the Reference Manual, each chapter consists of the following documents:

- Chapter Introduction, e.g. Introduction -- D01;
- Chapter Contents, e.g. Contents -- D01;
- routine documents, one for each documented routine in the chapter.

A routine document has the same name as the routine which it describes. Within each chapter, routine documents occur in alphanumerical order. As in the Handbook, chapters F06, X01 and X02 do not contain separate documentation for individual routines.

The general introductory documents, indexes and chapter introductions are the same in the Reference Manual as in the Handbook. The only exception is that the Essential Introduction contains a different Section 3 in the two publications, to describe the different forms of routine documentation.

1.3. On-line Documentation

Extensive on-line documentation is included as an integral part of the Foundation Library product. This consists of a number of components:

- general introductory material, including the Essential Introduction
- a summary list of all documented routines
- a KWIC Index
- Chapter Introductions
- routine documents
- example programs, data and results.

The material has been derived in a number of forms to cater for
different user requirements, e.g. UNIX man pages, plain text, RICH TEXT format etc, and the appropriate version is included on the distribution media. For each implementation of the Foundation Library the specific documentation (Installers' Note, Users' Note etc) gives details of what is provided.

1.4. Implementations of the Library

The NAG Foundation Library is available on many different computer systems. For each distinct system, an implementation of the Library is prepared by NAG, e.g. the IBM RISC System/6000 implementation. The implementation is distributed as a tested compiled library.

An implementation is usually specific to a range of machines; it may also be specific to a particular operating system or compilation system.

Essentially the same facilities are provided in all implementations of the Library, but, because of differences in arithmetic behaviour and in the compilation system, routines cannot be expected to give identical results on different systems, especially for sensitive numerical problems.

The documentation supports all implementations of the Library, with the help of a few simple conventions, and a small amount of implementation-dependent information, which is published in a separate Users' Note for each implementation (see Section 3.4).

1.5. Library Identification

You must know which implementation of the Library you are using or intend to use. To find out which implementation of the Library is available on your machine, you can run a program which calls the NAG Foundation Library routine A00AAF. This routine has no parameters; it simply outputs text to the advisory message unit (see Section 2.4). An example of the output is:

*** Start of NAG Foundation Library implementation details ***
Implementation title: IBM RISC System/6000
Precision: FORTRAN double precision
Product Code: FFIBM601D
Release: 1
*** End of NAG Foundation Library implementation details ***

(The product code can be ignored, except possibly when communicating with NAG; see Section 4.)

1.6. Fortran Language Standards
All routines in the Library conform to ANSI Standard Fortran 90 [8].

Most of the routines in the Library were originally written to conform to the earlier Fortran 66 [6] and Fortran 77 [7] standards, and their calling sequences contain some parameters which are not strictly necessary in Fortran 90.

2. Using the Library

2.1. General Advice

A NAG Foundation Library routine cannot be guaranteed to return meaningful results, irrespective of the data supplied to it. Care and thought must be exercised in:

(a) formulating the problem;

(b) programming the use of library routines;

(c) assessing the significance of the results.

2.2. Programming Advice

The NAG Foundation Library and its documentation are designed on the assumption that users know how to write a calling program in Fortran.

When programming a call to a routine, read the routine document carefully, especially the description of the Parameters. This states clearly which parameters must have values assigned to them on entry to the routine, and which return useful values on exit. See Section 3.3 for further guidance.

If a call to a Library routine results in an unexpected error message from the system (or possibly from within the Library), check the following:

Has the NAG routine been called with the correct number of parameters?

Do the parameters all have the correct type?

Have all array parameters been dimensioned correctly?

Remember that all floating-point parameters must be declared to be double precision, either with an explicit DOUBLE PRECISION declaration (or COMPLEX(KIND(1.DO)) if they are complex), or by
using a suitable IMPLICIT statement.

Avoid the use of NAG-type names for your own program units or COMMON blocks: in general, do not use names which contain a three-character NAG chapter name embedded in them; they may clash with the names of an auxiliary routine or COMMON block used by the NAG Library.

2.3. Error handling and the Parameter IFAIL

NAG Foundation Library routines may detect various kinds of error, failure or warning conditions. Such conditions are handled in a systematic way by the Library. They fall roughly into three classes:

(i) an invalid value of a parameter on entry to a routine;

(ii) a numerical failure during computation (e.g. approximate singularity of a matrix, failure of an iteration to converge);

(iii) a warning that although the computation has been completed, the results cannot be guaranteed to be completely reliable.

All three classes are handled in the same way by the Library, and are all referred to here simply as 'errors'.

The error-handling mechanism uses the parameter IFAIL, which is the last parameter in the calling sequence of most NAG Foundation Library routines. IFAIL serves two purposes:

(i) it allows users to specify what action a Library routine should take if it detects an error;

(ii) it reports the outcome of a call to a Library routine, either success (IFAIL = 0) or failure (IFAIL /= 0, with different values indicating different reasons for the failure, as explained in Section 6 of the routine document).

For the first purpose IFAIL must be assigned a value before calling the routine; since IFAIL is reset by the routine, it must be passed as a variable, not as an integer constant. Allowed values on entry are:

- IFAIL=0: an error message is output, and execution is terminated ('hard failure');
- IFAIL=+1: execution continues without any error message;
IFAIL=-1: an error message is output, and execution continues.

The settings IFAIL =+-1 are referred to as 'soft failure'. The safest choice is to set IFAIL to 0, but this is not always convenient: some routines return useful results even though a failure (in some cases merely a warning) is indicated. However, if IFAIL is set to +- 1 on entry, it is essential for the program to test its value on exit from the routine, and to take appropriate action.

The specification of IFAIL in Section 5 of a routine document suggests a suitable setting of IFAIL for that routine.

2.4. Input/output in the Library

Most NAG Foundation Library routines perform no output to an external file, except possibly to output an error message. All error messages are written to a logical error message unit. This unit number (which is set by default to 6 in most implementations) can be changed by calling the Library routine X04AAF.

Some NAG Foundation Library routines may optionally output their final results, or intermediate results to monitor the course of computation. All output other than error messages is written to a logical advisory message unit. This unit number (which is also set by default to 6 in most implementations) can be changed by calling the Library routine X04ABF. Although it is logically distinct from the error message unit, in practice the two unit numbers may be the same.

All output from the Library is formatted.

The only Library routines which perform input from an external file are a few 'option-setting' routines in Chapter E04: the unit number is a parameter to the routine, and all input is formatted.

You must ensure that the relevant Fortran unit numbers are associated with the desired external files, either by an OPEN statement in your calling program, or by operating system commands.

2.5. Auxiliary Routines

In addition to those Library routines which are documented and are intended to be called by users, the Library also contains many auxiliary routines.

In general, you need not be concerned with them at all, although
you may be made aware of their existence if, for example, you examine a memory map of an executable program which calls NAG routines. The only exception is that when calling some NAG Foundation Library routines, you may be required or allowed to supply the name of an auxiliary routine from the Library as an external procedure parameter. The routine documents give the necessary details. In such cases, you only need to supply the name of the routine; you never need to know details of its parameter-list.

NAG auxiliary routines have names which are similar to the name of the documented routine(s) to which they are related, but with last letter 'Z', 'Y', and so on, e.g. D01AJZ is an auxiliary routine called by D01AJF.

3.1. General Guidance

The Reference Manual is designed to serve the following functions:

-- to give background information about different areas of numerical and statistical computation;

-- to advise on the choice of the most suitable NAG Foundation Library routine or routines to solve a particular problem;

-- to give all the information needed to call a NAG Foundation Library routine correctly from a Fortran program, and to assess the results.

At the beginning of the Manual are some general introductory documents. The following may help you to find the chapter, and possibly the routine, which you need to solve your problem:

Contents    -- a list of routines in the Library, by Summary        chapter;

KWIC Index  -- a keyword index to chapters and routines.

Having found a likely chapter or routine, you should read the corresponding Chapter Introduction, which gives background information about that area of numerical computation, and recommendations on the choice of a routine, including indexes, tables or decision trees.

When you have chosen a routine, you must consult the routine document. Each routine document is essentially self-contained (it
Example programs which illustrate the use of each routine are distributed with the Library in machine-readable form.

3.2. Structure of Routine Documents

All routine documents have the same structure, consisting of nine numbered sections:

1. Purpose
2. Specification
3. Description
4. References
5. Parameters (see Section 3.3 below)
6. Error Indicators
7. Accuracy
8. Further Comments
9. Example (see Section 3.5 below)

In a few documents, Section 5 also includes a description of printed output which may optionally be produced by the routine.

3.3. Specifications of Parameters

Section 5 of each routine document contains the specification of the parameters, in the order of their appearance in the parameter list.

3.3.1. Classification of Parameters

Parameters are classified as follows:

Input: you must assign values to these parameters on or before entry to the routine, and these values are unchanged on exit from the routine.

Output: you need not assign values to these parameters on or before entry to the routine; the routine may assign values to
them.

Input/Output: you must assign values to these parameters on or before entry to the routine, and the routine may then change these values.

Workspace: array parameters which are used as workspace by the routine. You must supply arrays of the correct type and dimension, but you need not be concerned with their contents.

External Procedure: a subroutine or function which must be supplied (e.g. to evaluate an integrand or to print intermediate output). Usually it must be supplied as part of your calling program, in which case its specification includes full details of its parameter-list and specifications of its parameters (all enclosed in a box). Its parameters are classified in the same way as those of the Library routine, but because you must write the procedure rather than call it, the significance of the classification is different:

- Input: values may be supplied on entry, which your procedure must not change.
- Output: you may or must assign values to these parameters before exit from your procedure.
- Input/Output: values may be supplied on entry, and you may or must assign values to them before exit from your procedure.

Occasionally, as mentioned in Section 2.5, the procedure can be supplied from the NAG Library, and then you only need to know its name.

User Workspace: array parameters which are passed by the Library routine to an external procedure parameter. They are not used by the routine, but you may use them to pass information between your calling program and the external procedure.

3.3.2. Constraints and Suggested Values

The word 'Constraint:' or 'Constraints:' in the specification of an Input parameter introduces a statement of the range of valid values for that parameter, e.g.

Constraint: \( N > 0 \).

If the routine is called with an invalid value for the parameter (e.g. \( N = 0 \)), the routine will usually take an error exit, returning a non-zero value of IFAIL (see Section 2.3).
In newer documents constraints on parameters of type CHARACTER only list uppercase alphabetic characters, e.g.

Constraint: STRING = 'A' or 'B'.

In practice all routines with CHARACTER parameters will permit the use of lower case characters.

The phrase 'Suggested Value:' introduces a suggestion for a reasonable initial setting for an Input parameter (e.g. accuracy or maximum number of iterations) in case you are unsure what value to use; you should be prepared to use a different setting if the suggested value turns out to be unsuitable for your problem.

3.3.3. Array Parameters

Most array parameters have dimensions which depend on the size of the problem. In Fortran terminology they have 'adjustable dimensions': the dimensions occurring in their declarations are integer variables which are also parameters of the Library routine.

For example, a Library routine might have the specification:

```fortran
SUBROUTINE <name> (M, N, A, B, LDB)
  INTEGER M, N, A(N), B(LDB,N), LDB
```

For a one-dimensional array parameter, such as A in this example, the specification would begin:

3: A(N) -- DOUBLE PRECISION array Input

You must ensure that the dimension of the array, as declared in your calling (sub)program, is at least as large as the value you supply for N. It may be larger; but the routine uses only the first N elements.

For a two-dimensional array parameter, such as B in the example, the specification might be:

4: B(LDB,N) -- DOUBLE PRECISION array Input/Output
   On entry: the m by n matrix B.

and the parameter LDB might be described as follows:

5: LDB -- INTEGER Input
   On entry: the first dimension of the array B as declared in
the (sub)program from which <name> is called. Constraint: LDB >= M.

You must supply the first dimension of the array B, as declared in your calling (sub)program, through the parameter LDB, even though the number of rows actually used by the routine is determined by the parameter M. You must ensure that the first dimension of the array is at least as large as the value you supply for M. The extra parameter LDB is needed because Fortran does not allow information about the dimensions of array parameters to be passed automatically to a routine.

You must also ensure that the second dimension of the array, as declared in your calling (sub)program, is at least as large as the value you supply for N. It may be larger, but the routine only uses the first N columns.

A program to call the hypothetical routine used as an example in this section might include the statements:

    INTEGER AA(100), BB(100,50)
    LDB = 100
    ...
    M = 80
    N = 20
    CALL <name>(M,N,AA,BB,LDB)

Fortran requires that the dimensions which occur in array declarations, must be greater than zero. Many NAG routines are designed so that they can be called with a parameter like N in the above example set to 0 (in which case they would usually exit immediately without doing anything). If so, the declarations in the Library routine would use the 'assumed size' array dimension, and would be given as:

    INTEGER M, N, A(*), B(LDB,*), LDB

However, the original declaration of an array in your calling program must always have constant dimensions, greater than or equal to 1.

Consult an expert or a textbook on Fortran, if you have difficulty in calling NAG routines with array parameters.

3.4. Implementation-dependent Information
In order to support all implementations of the Foundation Library, the Manual has adopted a convention of using bold italics to distinguish terms which have different interpretations in different implementations.

For example, machine precision denotes the relative precision to which double precision floating-point numbers are stored in the computer, e.g. in an implementation with approximately 16 decimal digits of precision, machine precision has a value of

\[-16\approx10\]

approximately 10. The precise value of machine precision is given by the function X02AJF. Other functions in Chapter X02 return the values of other implementation-dependent constants, such as the overflow threshold, or the largest representable integer. Refer to the X02 Chapter Introduction for more details.

For each implementation of the Library, a separate Users' Note is provided. This is a short document, revised at each Mark. At most installations it is available in machine-readable form. It gives any necessary additional information which applies specifically to that implementation, in particular:

-- the interpretation of bold italicised terms;

-- the values returned by X02 routines;

-- the default unit numbers for output (see Section 2.4).

3.5. Example Programs and Results

The last section of each routine document describes an example problem which can be solved by simple use of the routine. The example programs themselves, together with data and results, are not printed in the routine document, but are distributed in machine-readable form with the Library. The programs are designed so that they can fairly easily be modified, and so serve as the basis for a simple program to solve a user's own problem.

The results distributed with each implementation were obtained using that implementation of the Library; they may not be identical to the results obtained with other implementations.

3.6. Summary for New Users

If you are unfamiliar with the NAG Foundation Library and are thinking of using a routine from it, please follow these instructions:
(a) read the whole of the Essential Introduction;

(b) consult the Contents Summary or KWIC Index to choose an appropriate chapter or routine;

(c) read the relevant Chapter Introduction;

(d) choose a routine, and read the routine document. If the routine does not after all meet your needs, return to steps (b) or (c);

(e) read the Users' Note for your implementation;

(f) consult local documentation, which should be provided by your local support staff, about access to the NAG Library on your computing system.

You should now be in a position to include a call to the routine in a program, and to attempt to run it. You may of course need to refer back to the relevant documentation in the case of difficulties, for advice on assessment of results, and so on.

As you become familiar with the Library, some of steps (a) to (f) can be omitted, but it is always essential to:

-- be familiar with the Chapter Introduction;

-- read the routine document;

-- be aware of the Users' Note for your implementation.

4. Relationship between the Foundation Library and other NAG Libraries

4.1. NAG Fortran Library

The Foundation Library is a strict subset of the full NAG Fortran Library (Mark 15 or later). Routines in both libraries have identical source code (apart from any modifications necessary for implementation on a specific system) and hence can be called in exactly the same way, though you should consult the relevant implementation-specific documentation for details such as values of machine constants.

By its very nature, the Foundation Library cannot contain the same extensive range of routines as the full Fortran Library. If your application requires a routine which is not in the Foundation Library, then please consult NAG for information on relevant material available in the Fortran Library.
Some routines which occur as user-callable routines in the full Fortran Library are included as auxiliary routines in the Foundation Library but they are not documented in this publication and direct calls to them should only be made if you are already familiar with their use in the Fortran Library. A list of all such auxiliary routines is given at the end of the Foundation Library Contents Summary.

 Whereas the full Fortran Library may be provided in either a single precision or a double precision version, the Foundation Library is always provided in double precision.

4.2. NAG Workstation Library

The Foundation Library is a successor product to an earlier, smaller subset of the full NAG Fortran Library which was called the NAG Workstation Library. The Foundation Library has greater functionality than the Workstation Library but is not strictly upwards compatible, i.e., a number of routines in the earlier product have been replaced by new material to reflect recent algorithmic developments.

If you have used the Workstation Library and wish to convert your programs to call routines from the Foundation Library, please consult the document 'Converting from the Workstation Library' in this Manual.

4.3. NAG C Library

NAG has also developed a library of numerical and statistical software for use by C programmers. This now contains over 200 user-callable functions and provides similar (but not identical) coverage to that of the Foundation Library. Please contact NAG for further details if you have a requirement for similar quality library code in C.

5. Contact between Users and NAG

If you are using the NAG Foundation Library in a multi-user environment and require further advice please consult your local support staff who will be receiving regular information from NAG. This covers such matters as:

-- obtaining a copy of the Users' Note for your implementation;

-- obtaining information about local access to the Library;

-- seeking advice about using the Library;
-- reporting suspected errors in routines or documents;
-- making suggestions for new routines or features;
-- purchasing NAG documentation.

If you are unable to make contact with a local source of support or are in a single-user environment then please contact NAG directly at any one of the addresses given at the beginning of this publication.

6. General Information about NAG

NAG produces and distributes numerical, symbolic, statistical and graphical software for the solution of problems in a wide range of applications in such areas as science, engineering, financial analysis and research.

For users who write programs and build packages NAG produces subprogram libraries in a range of computer languages (Ada, C, Fortran, Pascal, Turbo Pascal). NAG also provides a number of Fortran programming support products in the NAGWare range -- Fortran 77 programming tools, Fortran 90 compilers for a number of machine platforms (including PC-DOS) and VecPar 77 for restructuring and tuning programs for execution on vector or parallel computers.

For users who do not wish to program in the traditional sense but want the same reliability and qualities offered by our libraries, NAG provides several powerful mathematical and statistical packages for interactive use. A major addition to this range of packages is Axiom -- the powerful symbolic solver which includes a Hypertext system and graphical capabilities.

For further details of any of these products, please contact NAG at one of the addresses given at the beginning of this publication.

References [2], [3], [4], and [5] discuss various aspects of the design and development of the NAG Library, and NAG's technical policies and organisation.

Pseudo-random real numbers, uniform distribution over (0,1) G05CAF

Pseudo-random real numbers, Normal distribution G05DDF

Pseudo-random real numbers, Cauchy distribution G05DFF

Pseudo-random real numbers, Weibull distribution G05DPF

Pseudo-random integer from uniform distribution G05DYF

Pseudo-random logical (boolean) value G05DZF

Set up reference vector for generating pseudo-random integers, Poisson distribution G05ECF

Set up reference vector for generating pseudo-random integers, binomial distribution G05EDF

Pseudo-random permutation of an integer vector G05EHF

Pseudo-random sample from an integer vector G05EJF

Pseudo-random integer from reference vector G05EYF

Pseudo-random multivariate Normal vector from reference vector G05EZF

Generates a vector of pseudo-random numbers from a beta distribution G05FEF

Generates a vector of pseudo-random numbers from a gamma distribution G05FFF

Incomplete gamma functions P(a,x) and Q(a,x) S14BAF
22.1. NAGAUX.HT

QP problem

Minimum, function of several variables, sequential QP method, nonlinear constraints, using function values and ...

QR factorization of real m by n matrix (m<=n)

QR factorization of complex m by n matrix (m<=n)

1-D quadrature, adaptive, finite interval, strategy due to ...

1-D quadrature, adaptive, finite interval, method suitable for ...

1-D quadrature, adaptive, finite interval, allowing for ...

1-D quadrature, adaptive, infinite or semi-infinite interval

1-D quadrature, adaptive, finite interval, weight function cos((omega)x) ...

1-D quadrature, adaptive, finite interval, weight function with ...

1-D quadrature, adaptive, finite interval, weight function ...

1-D quadrature, adaptive, semi-infinite interval, weight function ...

Pre-computed weights and abscissae for Gaussian quadrature rules, restricted choice of rule
Multi-dimensional adaptive quadrature over hyper-rectangle D01FCF

1-D quadrature, integration of function defined by data values, ... D01GAF

Multi-dimensional quadrature over hyper-rectangle, Monte Carlo method D01GBF

quasi-Newton algorithm, using 1st derivatives

Minimum, function of several variables, quasi-Newton algorithm, simple bounds, using function values ... E04JAF

QZ algorithm, real matrices

Pseudo-random real numbers, uniform distribution over (0,1) G05CAF

Initialise random number generating routines to give repeatable sequence G05CBF

Initialise random number generating routines to give non-repeatable ... G05CCF

Save state of random number generating routines G05CFF

Restore state of random number generating routines G05CGF

Pseudo-random real numbers, Normal distribution G05DDF

Pseudo-random real numbers, Cauchy distribution G05dff
Pseudo-
random real numbers, Weibull distribution

Pseudo-
random integer from uniform distribution

Pseudo-
random logical (boolean) value

Set up reference vector for generating pseudo-
random integers, Poisson distribution

Set up reference vector for generating pseudo-
random integers, binomial distribution

Pseudo-
random permutation of an integer vector

Pseudo-
random sample from an integer vector

Pseudo-
random integer from reference vector

Pseudo-
random multivariate Normal vector from reference vector

Generates a vector of random numbers from a uniform distribution

Generates a vector of random numbers from an (negative) exponential distribution

Generates a vector of random numbers from a Normal distribution

Generates a vector of pseudo-
random numbers from a beta distribution
Generates a vector of pseudo-random numbers from a gamma distribution

ODEs, IVP, Runge-Kutta-Merson method, over a range, intermediate output
range, eigenvalue and eigenfunction, user-specified ...

Safe range of floating-point arithmetic
Safe range of complex floating-point arithmetic

Least-squares (if rank=n)
or minimal least-squares (if rank<n) ...

rank <n) solution of m real equations in n unknowns, ...
rank <=n,m>=n

Rank-1 update, real rectangular matrix (DGER)
Rank-1 update, real symmetric matrix (DSYR)
Rank-1 update, real symmetric packed matrix (DSPR)

Rank-2 update, real symmetric matrix (DSYR2)
Rank-2 update, real symmetric packed matrix (DSPR2)

Rank-1 update, complex rectangular matrix, unconjugated ...
22.1. NAGAUX.HT

Rank-1 F06SNF update, complex rectangular matrix, conjugated vector.

Rank-1 F06SPF update, complex Hermitian matrix (ZHER)

Rank-1 F06SQF update, complex Hermitian packed matrix (ZHPR)

Rank-2 F06SRF update, complex Hermitian matrix (ZHER2)

Rank-2 F06SSF update, complex Hermitian packed matrix (ZHPR2)

Rank-k F06YPF update of a real symmetric matrix (DSYRK)

Rank-2k F06YRF update of a real symmetric matrix (DSYR2K)

Rank-k F06ZPF update of a complex Hermitian matrix (ZHERK)

Rank-2k F06ZRF update of a complex Hermitian matrix (ZHER2K)

Rank-k F06ZUF update of a complex symmetric matrix (ZSYRK)

Rank-2k F06ZWF update of a complex symmetric matrix (ZHER2K)

Kendall/Spearman non-parametric rank correlation coefficients, no missing values, overwriting ...

Kendall/Spearman non-parametric rank correlation coefficients, no missing values, preserving rank test

Rank M01DAF a vector, real numbers

Rank M01DEF rows of a matrix, real numbers
Rank columns of a matrix, real numbers

Rearrange a vector according to given ranks, real numbers

Generates a realisation of a multivariate time series from a VARMA model

Rearrange a vector according to given ranks, real numbers

Multi-dimensional adaptive quadrature over hyper-rectangle

Multi-dimensional quadrature over hyper-rectangle, Monte Carlo method

Discretize a 2nd order elliptic PDE on a rectangular grid

Matrix-vector product, real rectangular matrix (Dgemv)

Matrix-vector product, real rectangular band matrix (Dgbmv)

Rank-1 update, real rectangular matrix (Dger)

Matrix-vector product, complex rectangular matrix (Zgemv)

Matrix-vector product, complex rectangular band matrix (Zgbmv)

CHAPTER 22. NAG LIBRARY ROUTINES

vector

Pseudo-random multivariate Normal vector from reference vector

refinement

refinement

Simple linear regression with constant term, no missing values

Fits a general (multiple) linear regression model

Fits a general linear regression model for new dependent variable

Computes estimable function of a general linear regression model and its standard error

Nonlinear regression

2nd order Sturm-Liouville problem, regular/singular system, finite/infinite range, eigenvalue ...

Interpolating functions, method of Renka and Cline, two variables

Calculates standardized residuals and influence statistics

Univariate time series, diagnostic checking of residuals, following G13AFF

right-hand sides

Solution of real simultaneous linear equations, one right-hand side
right-hand side using iterative refinement

Solution of real simultaneous linear equations, one right-hand side using iterative refinement

right-hand side

Solves a system of equations with multiple right-hand sides, real triangular coefficient matrix (DTRSM)

Solves system of equations with multiple right-hand sides, complex triangular coefficient matrix (ZTRSM)

Solution of real system of linear equations, multiple right-hand sides, matrix already factorized by F07ADF (DGETRS)

right-hand sides, matrix already factorized by F07DF (DPOTRS)

Generate real plane rotation (DROTG)

Apply real plane rotation (DROT)

Computes orthogonal rotations for loading matrix, generalized orthomax criterion rules, restricted choice of rule

rule

ODEs, IVP, Runge-Kutta-Merson method, over a range, intermediate output

Matrix-vector product, real symmetric band matrix (DSBMV)

Matrix-vector product, real symmetric packed matrix (DSPMV)

Rank-1 update, real symmetric matrix (DSYR)

Rank-1 update, real symmetric packed matrix (DSPR)

Rank-2 update, real symmetric matrix (DSYR2)
22.1. NAGAUX.HT

Rank-2 update, real symmetric packed matrix (DSPR2)

Matrix-matrix product, one real symmetric matrix, one real rectangular matrix (DSYMM)

Rank-k update of a real symmetric matrix (DSYRK)

Rank-2k update of a real symmetric matrix (DSYR2K)

Matrix-matrix product, one complex symmetric matrix, one complex rectangular matrix (ZSYMM)

Rank-k update of a complex symmetric matrix (ZSYRK)

Rank-2k update of a complex symmetric matrix (ZHER2K)

Cholesky factorization of real symmetric positive-definite matrix (DPOTRF)

Solution of real symmetric positive-definite system of linear equations, ...

Degenerate symmetrised elliptic integral of 1st kind \( R(x,y) \)

Symmetrised elliptic integral of 1st kind \( R(x,y,z) \)

Symmetrised elliptic integral of 2nd kind \( R(x,y,z) \)
Symmetrised elliptic integral of 3rd kind $R(x,y,z,r)$

Solution of system of nonlinear equations using function values only

Solution of system of nonlinear equations using 1st derivatives

2nd order Sturm-Liouville problem, regular/singular system, finite/infinite range, eigenvalue and eigenfunction,

System of equations, real triangular matrix (DTRSV)

System of equations, real triangular band matrix (DTBSV)

System of equations, real triangular packed matrix (DTPSV)

System of equations, complex triangular matrix (ZTRSV)

System of equations, complex triangular band matrix (ZTBSV)

System of equations, complex triangular packed matrix (ZTPSV)

Solves a system of equations with multiple right-hand sides, real ...

Solves system of equations with multiple right-hand sides, complex ..

Solution of real system of linear equations, multiple right-hand sides, matrix

Solution of real symmetric positive-definite system of linear equations, multiple right-hand sides, matrix
Computes probabilities for Student’s t-distribution

Computes deviates for Student’s t-distribution

table

Frequency table from raw data

Two-way contingency table

2 analysis, with (chi) /Fisher’s exact test

Computes upper and lower tail and probability density function probabilities for the test

Sign test on two paired samples

Median test on two samples of unequal size test

Performs the Mann-Whitney U test on two independent samples

2 Performs the (chi) goodness of fit test, for standard continuous distributions

Goodness of fit tests

Location tests

Non-parametric
tests

ties
in pooled sample

CONVERSION(3NAG) Foundation Library (12/10/92) CONVERSION(3NAG)

Introduction

Converting from the Workstation Library

The NAG Foundation Library is a successor product to an earlier, smaller subset of the full NAG Fortran Library which was called the NAG Workstation Library. The Foundation Library has been designed to be upwards compatible, in terms of functionality, with the Workstation Library. However some routines that were present in the Workstation Library have been replaced by more up-to-date routines from the NAG Fortran Library, which provide improved algorithms or software design.

The list below gives the names of those routines which were available in the Workstation Library, but are not included in the Foundation Library. For each such routine, it also gives the name of the routine in the Foundation Library which best covers the same functionality.

<table>
<thead>
<tr>

Notes:

1. E04ZCF checks user-supplied routines for evaluating the first derivatives of the objective function and constraint functions supplied to E04VDF. This functionality is now provided by E04UCF, using the optional parameters Verify Objective Gradients and Verify Constraint Gradients.

2. G02CEF selects variables to be included in a linear regression performed by G02CGF. This functionality is now
provided by the parameter ISX of G02DAF.

3. A call to G05DCF can be replaced by a simple transformation of the result of a call to G05CAF. The statement
   \[ X = \text{G05DCF}(A, B) \]
   can be replaced by the statements
   \[ X = \text{G05CAF}(X) \]
   \[ X = A + B \times \log(X/(1.0D0 - X)) \]

4. G05DHF generates random numbers from a (chi) distribution with \( N \) degrees of freedom. This can be achieved by calling G05FFF with the values \( \text{DBLE}(N)/2.0D0 \) and \( 2.0D0 \) for the parameters \( A \) and \( B \) respectively.

22.2 nagc.ht

Zeros of Polynomials

--- nagc.ht ---

This chapter is concerned with computing the zeros of a polynomial with real or complex coefficients.
2. Background to the Problems

Let \( f(z) \) be a polynomial of degree \( n \) with complex coefficients \( a_i \):

\[
f(z) = a_n z^n + a_{n-1} z^{n-1} + \ldots + a_1 z + a_0, \quad a_i \neq 0.
\]

A complex number \( z \) is called a zero of \( f(z) \) (or equivalently a root of the equation \( f(z) = 0 \)), if:

\[
f(z) = 0.
\]

If \( z \) is a zero, then \( f(z) \) can be divided by a factor \((z - z_1)\):

\[
f(z) = (z - z_1) f_1(z)
\]

where \( f_1(z) \) is a polynomial of degree \( n - 1 \). By the Fundamental Theorem of Algebra, a polynomial \( f(z) \) always has a zero, and so the process of dividing out factors \((z - z_i)\) can be continued until we have a complete factorization of \( f(z) \):

\[
f(z) = (z - z_1)(z - z_2) \ldots (z - z_n).
\]

Here the complex numbers \( z_1, z_2, \ldots, z_n \) are the zeros of \( f(z) \); they may not all be distinct, so it is sometimes more convenient to write:

\[
f(z) = (z - z_1)^{m_1}(z - z_2)^{m_2} \ldots (z - z_k)^{m_k}, \quad k \leq n,
\]

with distinct zeros \( z_1, z_2, \ldots, z_k \) and multiplicities \( m_i \geq 1 \). If \( m_i = 1 \), \( z_i \) is called a single zero, if \( m_i > 1 \), \( z_i \) is called a multiple or repeated zero; a multiple zero is also a zero of the derivative of \( f(z) \).
If the coefficients of \( f(z) \) are all real, then the zeros of \( f(z) \) are either real or else occur as pairs of conjugate complex numbers \( x+iy \) and \( x-iy \). A pair of complex conjugate zeros are the zeros of a quadratic factor of \( f(z) \), \((z + rz + s)\), with real coefficients \( r \) and \( s \).

Mathematicians are accustomed to thinking of polynomials as pleasantly simple functions to work with. However the problem of numerically computing the zeros of an arbitrary polynomial is far from simple. A great variety of algorithms have been proposed, of which a number have been widely used in practice; for a fairly comprehensive survey, see Householder [1]. All general algorithms are iterative. Most converge to one zero at a time; the corresponding factor can then be divided out as in equation (1) above - this process is called deflation or, loosely, dividing out the zero - and the algorithm can be applied again to the polynomial \( f(z) \). A pair of complex conjugate zeros can be divided out together - this corresponds to dividing \( f(z) \) by a quadratic factor.

Whatever the theoretical basis of the algorithm, a number of practical problems arise: for a thorough discussion of some of them see Peters and Wilkinson [2] and Wilkinson [3]. The most elementary point is that, even if \( z \) is mathematically an exact zero of \( f(z) \), because of the fundamental limitations of computer arithmetic the computed value of \( f(z) \) will not necessarily be exactly 0.0. In practice there is usually a small region of values of \( z \) about the exact zero at which the computed value of \( f(z) \) becomes swamped by rounding errors. Moreover in many algorithms this inaccuracy in the computed value of \( f(z) \) results in a similar inaccuracy in the computed step from one iterate to the next. This limits the precision with which any zero can be computed. Deflation is another potential cause of trouble, since, in the notation of equation (1), the computed coefficients of \( f(z) \) will not be completely accurate, especially if \( z \) is not an exact zero of \( f(z) \); so the zeros of the computed \( f(z) \) will deviate from the zeros of \( f(z) \).

A zero is called ill-conditioned if it is sensitive to small changes in the coefficients of the polynomial. An ill-conditioned zero is likewise sensitive to the computational inaccuracies just mentioned. Conversely a zero is called well-conditioned if it is comparatively insensitive to such perturbations. Roughly speaking
a zero which is well separated from other zeros is well-conditioned, while zeros which are close together are ill-conditioned, but in talking about 'closeness' the decisive factor is not the absolute distance between neighbouring zeros but their ratio: if the ratio is close to 1 the zeros are ill-conditioned. In particular, multiple zeros are ill-conditioned. A multiple zero is usually split into a cluster of zeros by perturbations in the polynomial or computational inaccuracies.

2.1. References

3. Recommendations on Choice and Use of Routines

3.1. Discussion

Two routines are available: C02AFF for polynomials with complex coefficients and C02AGF for polynomials with real coefficients.

C02AFF and C02AGF both use a variant of Laguerre’s Method due to BT Smith to calculate each zero until the degree of the deflated polynomial is less than 3, whereupon the remaining zeros are obtained using the ‘standard’ closed formulae for a quadratic or linear equation.

The accuracy of the roots will depend on how ill-conditioned they are. Peters and Wilkinson [2] describe techniques for estimating the errors in the zeros after they have been computed.

Roots of a complex polynomial equation

--- nagc.ht ---

C02AFF finds all the roots of a complex polynomial equation, using a variant of Laguerre's Method.

2. Specification

```fortran
SUBROUTINE C02AFF (A, N, SCALE, Z, W, IFAIL)
INTEGER N, IFAIL
DOUBLE PRECISION A(2,N+1), Z(2,N), W(4*(N+1))
LOGICAL SCALE
```

3. Description

The routine attempts to find all the roots of the nth degree complex polynomial equation
\[ P(z) = a_n z^n + a_{n-1} z^{n-1} + \ldots + a_2 z^2 + a_1 z + a_0 = 0. \]

The roots are located using a modified form of Laguerre's Method, originally proposed by Smith [2].

The method of Laguerre [3] can be described by the iterative scheme

\[
\begin{align*}
L(z) &= z_k - \frac{-n*P(z)}{P'(z_k) + \sqrt{H(z_k)}}, \\
H(z_k) &= (n-1)\left[(n-1)\left(P'(z_k)^2 - n*P(z_k)P''(z_k)\right)\right], \quad \text{and } z_k \text{ is specified.}
\end{align*}
\]

where \( H(z_k) = (n-1)\left[(n-1)\left(P'(z_k)^2 - n*P(z_k)P''(z_k)\right)\right], \) and \( z_k \) is specified.

The sign in the denominator is chosen so that the modulus of the Laguerre step at \( z_k \), viz. \(|L(z_k)|\), is as small as possible. The method can be shown to be cubically convergent for isolated roots (real or complex) and linearly convergent for multiple roots. The routine generates a sequence of iterates \( z_1, z_2, z_3, \ldots \), such that \(|P(z_k)| < |P(z_{k+1})|\) and ensures that \( z_{k+1} + L(z_k) \) 'roughly' lies inside a circular region of radius \(|F_k|\) about \( z_k \) known to contain a zero of \( P(z) \); that is, \(|L(z_k)| < |F_k|\), where \( F_k \) denotes the Fejer bound (see Marden [1]) at the point \( z_k \). Following Smith [2], \( F_k \) is taken to be \( \min(B, 1.445*n*R) \), where \( B \) is an upper bound for the magnitude of the smallest zero given by

\[
B = 1.0001 \times \min(\sqrt{n} \times L(z_k), |r|, |a_n/a_0|),
\]

where \( r \) is the zero \( X \) of smaller magnitude of the quadratic equation

\[
2(P'(z_k)/(2*n*(n-1)))X^2 + 2(P'(z_k)/n)X + P(z_k) = 0
\]
and the Cauchy lower bound \( R \) for the smallest zero is computed (using Newton’s Method) as the positive root of the polynomial equation

\[
|a_0 z^n + a_1 z^{n-1} + a_2 z^{n-2} + \cdots + a_{n-1} z + a_n| = 0.
\]

Starting from the origin, successive iterates are generated according to the rule \( z_k = z_{k-1} + L(z_{k-1}) \) for \( k = 1, 2, 3, \ldots \) and \( L(z_k) \) is ‘adjusted’ so that \( |P(z_k)| < |P(z_{k-1})| \) and \( |L(z_k)| < |F| \). The iterative procedure terminates if \( P(z_k) \) is smaller in absolute value than the bound on the rounding error in \( P(z_k) \) and the current iterate \( z_k \) is taken to be a zero of \( P(z) \). The deflated polynomial \( P(z) = P(z) / (z - z_k) \) of degree \( n - 1 \) is then formed, and the above procedure is repeated on the deflated polynomial until \( n < 3 \), whereupon the remaining roots are obtained via the ‘standard’ closed formulae for a linear (\( n = 1 \)) or quadratic (\( n = 2 \)) equation.

To obtain the roots of a quadratic polynomial, C02AHF(*) can be used.

4. References

5. Parameters

1: A(2,N+1) -- DOUBLE PRECISION array Input
   On entry: if A is declared with bounds \((2,0: N)\), then \( A(1,i) \) and \( A(2,i) \) must contain the real and imaginary parts of a
(i.e., the coefficient of $z^{n-i}$), for $i=0,1,...,n$.
Constraint: $A(1,0) \neq 0.0$ or $A(2,0) \neq 0.0$.

2: $N$ -- INTEGER Input
On entry: the degree of the polynomial, $n$. Constraint: $N \geq 1$.

3: $SCALE$ -- LOGICAL Input
On entry: indicates whether or not the polynomial is to be scaled. See Section 8 for advice on when it may be preferable to set $SCALE = .FALSE.$ and for a description of the scaling strategy. Suggested value: $SCALE = .TRUE.$.

4: $Z(2,N)$ -- DOUBLE PRECISION array Output
On exit: the real and imaginary parts of the roots are stored in $Z(1,i)$ and $Z(2,i)$ respectively, for $i=1,2,...,n$.

5: $W(4*(N+1))$ -- DOUBLE PRECISION array Workspace

6: $IFAIL$ -- INTEGER Input/Output
On entry: $IFAIL$ must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
On exit: $IFAIL = 0$ unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry $IFAIL = 0$ or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

$IFAIL= 1$
On entry $A(1,0) = 0.0$ and $A(2,0) = 0.0$,
or $N < 1$.

$IFAIL= 2$
The iterative procedure has failed to converge. This error is very unlikely to occur. If it does, please contact NAG immediately, as some basic assumption for the arithmetic has been violated. See also Section 8.

$IFAIL= 3$
Either overflow or underflow prevents the evaluation of $P(z)$ near some of its zeros. This error is very unlikely to
occur. If it does, please contact NAG immediately. See also Section 8.

7. Accuracy

All roots are evaluated as accurately as possible, but because of the inherent nature of the problem complete accuracy cannot be guaranteed.

8. Further Comments

If SCALE = .TRUE., then a scaling factor for the coefficients is chosen as a power of the base B of the machine so that the largest coefficient in magnitude approaches THRESH = B^{EMAX-P}.

Users should note that no scaling is performed if the largest coefficient in magnitude exceeds THRESH, even if SCALE = .TRUE. (For definition of B, EMAX and P see the Chapter Introduction X02.)

However, with SCALE = .TRUE., overflow may be encountered when the input coefficients $a_0, a_1, a_2, \ldots, a_n$ vary widely in magnitude, particularly on those machines for which $B$ overflows. In such cases, SCALE should be set to .FALSE. and the coefficients scaled so that the largest coefficient in magnitude does not exceed $B^{(EMAX-2*P)}$.

Even so, the scaling strategy used in C02AFF is sometimes insufficient to avoid overflow and/or underflow conditions. In such cases, the user is recommended to scale the independent variable $z$ so that the disparity between the largest and smallest coefficient in magnitude is reduced. That is, use the routine to locate the zeros of the polynomial $d^*P(cz)$ for some suitable values of $c$ and $d$. For example, if the original polynomial was $P(z)=2+i2 \ z$ , then choosing $c=2$ and $d=2$ , for instance, would yield the scaled polynomial $i+z$ , which is well-behaved relative to overflow and underflow and has 10 zeros which are 2 times those of $P(z)$.

If the routine fails with IFAIL = 2 or 3, then the real and imaginary parts of any roots obtained before the failure occurred are stored in Z in the reverse order in which they were found. Let $n$ denote the number of roots found before the failure
ocurred. Then Z(1,n) and Z(2,n) contain the real and imaginary parts of the 1st root found, Z(1,n-1) and Z(2,n-1) contain the real and imaginary parts of the 2nd root found, ..., Z(1,n) and Z(2,n) contain the real and imaginary parts of the n-th root found. After the failure has occurred, the remaining 2*(n-n) elements of Z contain a large negative number (equal to 

\[-1/(X02AMF().\sqrt{2}).\]

9. Example

\[
\begin{array}{cccccc}
5 & 4 & 3 & 2 \\
0 & 1 & 2 & 3 & 4 & 5 \\
\end{array}
\]

To find the roots of the polynomial \(a_5 z^5 + a_4 z^4 + a_3 z^3 + a_2 z^2 + a_1 z + a_0 = 0,\)

where \(a_0 = (5.0+6.0i), a_1 = (30.0+20.0i), a_2 = -(0.2+6.0i), a_3 = (50.0+100000.0i), a_4 = -(2.0-40.0i)\) and \(a_5 = (10.0+1.0i).\)

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

C02AGF finds all the roots of a real polynomial equation, using a variant of Laguerre's Method.

2. Specification

SUBROUTINE C02AGF (A, N, SCALE, Z, W, IFAIL)
INTEGER N, IFAIL
DOUBLE PRECISION A(N+1), Z(2,N), W(2*(N+1))
LOGICAL SCALE

3. Description

The routine attempts to find all the roots of the nth degree real polynomial equation

\[ P(z) = a_n z^n + a_{n-1} z^{n-1} + \ldots + a_1 z + a_0 = 0. \]

The roots are located using a modified form of Laguerre's Method, originally proposed by Smith [2].

The method of Laguerre [3] can be described by the iterative scheme

\[ L(z) = \frac{-n P(z)}{P'(z) + \sqrt{H(z)}} \]

where \( H(z) = (n-1) \left[ (n-1) (P'(z)) - n P(z) P''(z) \right] \), and \( z \) is specified.

The sign in the denominator is chosen so that the modulus of the Laguerre step at \( z \), viz. \( |L(z)| \), is as small as possible. The
method can be shown to be cubically convergent for isolated roots (real or complex) and linearly convergent for multiple roots.

The routine generates a sequence of iterates $z_1, z_2, z_3, \ldots$, such that $|P(z_{k+1})| < |P(z_k)|$ and ensures that $z_{k+1} + L(z_k) \approx z_k$ to 'roughly' lie inside a circular region of radius $|F|$ about $z_k$ known to contain a zero of $P(z)$; that is, $|L(z_k)| \leq |F|$, where $F$ denotes the Fejer bound (see Marden [1]) at the point $z_k$. Following Smith [2], $F$ is taken to be $\min(B, 1.445^n R)$, where $B$ is an upper bound for the magnitude of the smallest zero given by

$$B = 1.0001 \times \min(\sqrt[n]{L(z_k)}, |r|_1, |a|_0/a_0)$$

$r$ is the zero $X$ of smaller magnitude of the quadratic equation

$$2(P''(z) / (2n(n-1))X^2 + 2P'(z)/nX + P(z) = 0$$

and the Cauchy lower bound $R$ for the smallest zero is computed (using Newton’s Method) as the positive root of the polynomial equation

$$|a_0|z^n + |a_1|z^{n-1} + \ldots + |a_{n-2}|z^2 + |a_{n-1}|z + |a_n| = 0.$$}

Starting from the origin, successive iterates are generated according to the rule $z_{k+1} = z_k + L(z_k)$ for $k=1,2,3,\ldots$ and $L(z)$ is the iterative procedure terminates if $P(z_{k+1})$ is smaller in absolute value than the bound on the rounding error in $P(z_k)$ and the current iterate $z_{k+1}$ is taken to be a zero of $P(z)$ (as is its conjugate $z_{k-1}$ if $z_k$ is complex). The deflated polynomial

$$P(z) = P(z)/(z - z_k)$$

of degree $n-1$ if $z_k$ is real.
22.2. NAGC.HT

\[ P(z) = \frac{P(z)}{((z-z_1)(z-z_2))} \] of degree \( n-2 \) if \( z \) is complex) is then formed, and the above procedure is repeated on the deflated polynomial until \( n<3 \), whereupon the remaining roots are obtained via the 'standard' closed formulae for a linear (\( n = 1 \)) or quadratic (\( n = 2 \)) equation.

To obtain the roots of a quadratic polynomial, C02AJF(*) can be used.

4. References

5. Parameters

1: \( A(N+1) \) -- DOUBLE PRECISION array Input
   On entry: if \( A \) is declared with bounds (0:N), then \( A(i) = \frac{n-i}{i} \)
   must contain a \( i \) (i.e., the coefficient of \( z^i \), for \( i=0,1,\ldots,n \)). Constraint: \( A(0) \neq 0.0 \).

2: \( N \) -- INTEGER Input
   On entry: the degree of the polynomial, \( n \). Constraint: \( N \geq 1 \).

3: \( SCALE \) -- LOGICAL Input
   On entry: indicates whether or not the polynomial is to be scaled. See Section 8 for advice on when it may be preferable to set \( SCALE = \) .FALSE. and for a description of the scaling strategy. Suggested value: \( SCALE = \) .TRUE..

4: \( Z(2,N) \) -- DOUBLE PRECISION array Output
   On exit: the real and imaginary parts of the roots are stored in \( Z(1,i) \) and \( Z(2,i) \) respectively, for \( i=1,2,\ldots,n \). Complex conjugate pairs of roots are stored in consecutive pairs of elements of \( Z \); that is, \( Z(1,i+1) = Z(1,i) \) and \( Z(2,i+1) = -Z(2,i) \)
5: W(2*(N+1)) -- DOUBLE PRECISION array 
   Workspace

6: IFAIL -- INTEGER 
   Input/Output
   On entry: IFAIL must be set to 0, -1 or 1. For users not
   familiar with this parameter (described in the Essential
   Introduction) the recommended value is 0.
   On exit: IFAIL = 0 unless the routine detects an error (see
   Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
   On entry A(0) = 0.0,
   or    N < 1.

IFAIL= 2
   The iterative procedure has failed to converge. This error
   is very unlikely to occur. If it does, please contact NAG
   immediately, as some basic assumption for the arithmetic has
   been violated. See also Section 8.

IFAIL= 3
   Either overflow or underflow prevents the evaluation of P(z)
   near some of its zeros. This error is very unlikely to
   occur. If it does, please contact NAG immediately. See also
   Section 8.

7. Accuracy

All roots are evaluated as accurately as possible, but because of
the inherent nature of the problem complete accuracy cannot be
guaranteed.

8. Further Comments

If SCALE = .TRUE., then a scaling factor for the coefficients is
chosen as a power of the base B of the machine so that the
EMAX-P
largest coefficient in magnitude approaches THRESH = B
. Users should note that no scaling is performed if the largest
coefficient in magnitude exceeds THRESH, even if SCALE = .TRUE..
(For definition of B, EMAX and P see the Chapter Introduction
X02.)
However, with SCALE = .TRUE., overflow may be encountered when the input coefficients $a_0, a_1, a_2, \ldots, a_n$ vary widely in magnitude, particularly on those machines for which $B$ overflows. In such cases, SCALE should be set to .FALSE. and the coefficients scaled so that the largest coefficient in magnitude does not exceed $B$.

Even so, the scaling strategy used in C02AGF is sometimes insufficient to avoid overflow and/or underflow conditions. In such cases, the user is recommended to scale the independent variable $(z)$ so that the disparity between the largest and smallest coefficient in magnitude is reduced. That is, use the routine to locate the zeros of the polynomial $d^*P(cz)$ for some suitable values of $c$ and $d$. For example, if the original polynomial was $P(z) = 2 + 2z^{+100} + 3z^{+100} + 4z^{+20} + 5z^{+20} + 6 = 0$, then choosing $c = 2$ and $d = 2$, for instance, would yield the scaled polynomial $1 + z^{+100}$, which is well-behaved relative to overflow and underflow and has 10 zeros which are 2 times those of $P(z)$.

If the routine fails with IFAIL = 2 or 3, then the real and imaginary parts of any roots obtained before the failure occurred are stored in $Z$ in the reverse order in which they were found. Let $n$ denote the number of roots found before the failure occurred. Then $Z(1,n)$ and $Z(2,n)$ contain the real and imaginary parts of the 1st root found, $Z(1,n-1)$ and $Z(2,n-1)$ contain the real and imaginary parts of the 2nd root found, ..., $Z(1,n)$ and $Z(2,n)$ contain the real and imaginary parts of the $n$th root found. After the failure has occurred, the remaining $2*(n-n)$ elements of $Z$ contain a large negative number (equal to $-1/(\text{X02AMF}().\sqrt{2})$).

9. Example

To find the roots of the 5th degree polynomial $5 + 4z + 3z^2 + 2z^3 + z^4 + z^5 = 0$.

C05(3NAG) Foundation Library (12/10/92) C05(3NAG)

C05 -- Roots of One or More Transcendental Equations

Introduction -- C05

Chapter C05

Roots of One or More Transcendental Equations

1. Scope of the Chapter

This chapter is concerned with the calculation of real zeros of continuous real functions of one or more variables. (Complex equations must be expressed in terms of the equivalent larger system of real equations.)

2. Background to the Problems

The chapter divides naturally into two parts.

2.1. A Single Equation

The first deals with the real zeros of a real function of a single variable f(x).

At present, there is only one routine with a simple calling sequence. This routine assumes that the user can determine an
initial interval \[[a,b]\] within which the desired zero lies, that is \(f(a)\cdot f(b)<0\), and outside which all other zeros lie. The routine then systematically subdivides the interval to produce a final interval containing the zero. This final interval has a length bounded by the user's specified error requirements; the end of the interval where the function has smallest magnitude is returned as the zero. This routine is guaranteed to converge to a simple zero of the function. (Here we define a simple zero as a zero corresponding to a sign-change of the function.) The algorithm used is due to Bus and Dekker.

2.2. Systems of Equations

The routines in the second part of this chapter are designed to solve a set of nonlinear equations in \(n\) unknowns

\[
f^T(x)=0, \quad i=1,2,...,n, \quad x=(x_1,x_2,...,x_n) \quad (1)
\]

where \(T\) stands for transpose.

It is assumed that the functions are continuous and differentiable so that the matrix of first partial derivatives of the functions, the Jacobian matrix \(J(x)=\frac{df}{dx}\) evaluated at \(x\), exists, though it may not be possible to calculate it directly.

The functions \(f\) must be independent, otherwise there will be an infinity of solutions and the methods will fail. However, even when the functions are independent the solutions may not be unique. Since the methods are iterative, an initial guess at the solution has to be supplied, and the solution located will usually be the one closest to this initial guess.

2.3. References

**CHAPTER 22. NAG LIBRARY ROUTINES**

3. Recommendations on Choice and Use of Routines

3.1. Zeros of Functions of One Variable

There is only one routine (C05ADF) for solving a single nonlinear equation. This routine is designed for solving problems where the function \( f(x) \) whose zero is to be calculated, can be coded as a user-supplied routine.

C05ADF may only be used when the user can supply an interval \([a,b]\) containing the zero, that is \( f(a)f(b) < 0 \).

3.2. Solution of Sets of Nonlinear Equations

The solution of a set of nonlinear equations

\[
\begin{align*}
    f_i(x_1, x_2, \ldots, x_n) &= 0, & i &= 1, 2, \ldots, n \\
    \text{(2)}
\end{align*}
\]

can be regarded as a special case of the problem of finding a minimum of a sum of squares

\[
\begin{align*}
    s(x) &= \frac{1}{2} \sum_{i=1}^{m} | f_i(x_1, x_2, \ldots, x_n) |, & m &= n \geq n \\
    \text{(3)}
\end{align*}
\]

So the routines in Chapter E04 of the Library are relevant as well as the special nonlinear equations routines.

There are two routines (C05NBF and C05PBF) for solving a set of nonlinear equations. These routines require the \( f \) (and possibly their derivatives) to be calculated in user-supplied routines. These should be set up carefully so the Library routines can work as efficiently as possible.

The main decision which has to be made by the user is whether to supply the derivatives \( \frac{df_i}{dx_j} \). It is advisable to do so if possible, since the results obtained by algorithms which use derivatives are generally more reliable than those obtained by algorithms which do not use derivatives.
C05PBF requires the user to provide the derivatives, whilst C05NBF does not. C05NBF and C05PBF are easy-to-use routines. A routine, C05ZAF, is provided for use in conjunction with C05PBF to check the user-provided derivatives for consistency with the functions themselves. The user is strongly advised to make use of this routine whenever C05PBF is used.

Firstly, the calculation of the functions and their derivatives should be ordered so that cancellation errors are avoided. This is particularly important in a routine that uses these quantities to build up estimates of higher derivatives.

Secondly, scaling of the variables has a considerable effect on the efficiency of a routine. The problem should be designed so that the elements of \( x \) are of similar magnitude. The same comment applies to the functions, all the \( f_i \) should be of comparable size.

The accuracy is usually determined by the accuracy parameters of the routines, but the following points may be useful:

(i) Greater accuracy in the solution may be requested by choosing smaller input values for the accuracy parameters. However, if unreasonable accuracy is demanded, rounding errors may become important and cause a failure.

(ii) Some idea of the accuracies of the \( x_i \) may be obtained by monitoring the progress of the routine to see how many figures remain unchanged during the last few iterations.

(iii) An approximation to the error in the solution \( x \), given by \( e \) where \( e \) is the solution to the set of linear equations

\[
J(x)e = -f(x)
\]

where \( f(x) = (f_1(x), f_2(x), \ldots, f_n(x)) \) (see Chapter F04).

(iv) If the functions \( f_i(x) \) are changed by small amounts \( \epsilon_i \), for \( i = 1, 2, \ldots, n \), then the corresponding change in the solution \( x \) is given approximately by \( \sigma \), where \( \sigma \) is the solution of the set of linear equations

\[
J(x)\sigma = -(\epsilon)
\]

(see Chapter F04).
Thus one can estimate the sensitivity of $x$ to any uncertainties in the specification of $f_i(x)$, for $i = 1, 2, \ldots, n$.

C05 -- Roots of One or More Transcendental Equations

C05ADF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

C05ADF locates a zero of a continuous function in a given interval by a combination of the methods of linear interpolation, extrapolation and bisection.

2. Specification

```
SUBROUTINE C05ADF (A, B, EPS, ETA, F, X, IFAIL)
   INTEGER IFAIL
   DOUBLE PRECISION A, B, EPS, ETA, F, X
   EXTERNAL F
```

3. Description

The routine attempts to obtain an approximation to a simple zero of the function \( f(x) \) given an initial interval \([a,b]\) such that \( f(a)\cdot f(b) \leq 0 \). The zero is found by calls to C05AZF(*) whose specification should be consulted for details of the method used.

The approximation \( x \) to the zero (alpha) is determined so that one or both of the following criteria are satisfied:

\[
(i) \ |x-(alpha)|<\text{EPS}, \\
(ii) \ |f(x)|<\text{ETA}.
\]

4. References

None.

5. Parameters

1: A -- DOUBLE PRECISION

Input
On entry: the lower bound of the interval, a.
2:  B -- DOUBLE PRECISION                  Input
    On entry: the upper bound of the interval, b. Constraint: B 
               /= A.

3:  EPS -- DOUBLE PRECISION                  Input
    On entry: the absolute tolerance to which the zero is 
               required (see Section 3). Constraint: EPS > 0.0.

4:  ETA -- DOUBLE PRECISION                  Input
    On entry: a value such that if |f(x)|<ETA, x is accepted as 
               the zero. ETA may be specified as 0.0 (see Section 7).

5:  F -- DOUBLE PRECISION FUNCTION, supplied by the user. 
    External Procedure
    F must evaluate the function f whose zero is to be 
    determined.

    Its specification is:

    DOUBLE PRECISION FUNCTION F (XX)
    DOUBLE PRECISION XX

1:  XX -- DOUBLE PRECISION                  Input
    On entry: the point at which the function must be 
               evaluated.
    F must be declared as EXTERNAL in the (sub)program from 
    which C05ADF is called. Parameters denoted as Input 
    must not be changed by this procedure.

6:  X -- DOUBLE PRECISION                  Output
    On exit: the approximation to the zero.

7:  IFAIL -- INTEGER                       Input/Output
    Before entry, IFAIL must be assigned a value. For users not 
    familiar with this parameter (described in the Essential 
    Introduction) the recommended value is 0.

    Unless the routine detects an error (see Section 6), IFAIL 
    contains 0 on exit.

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
    On entry EPS <= 0.0,

    or     A = B,
or \( F(A) \cdot F(B) > 0.0 \).

IFAIL= 2
Too much accuracy has been requested in the computation, that is, EPS is too small for the computer being used. The final value of X is an accurate approximation to the zero.

IFAIL= 3
A change in sign of \( f(x) \) has been determined as occurring near the point defined by the final value of X. However, there is some evidence that this sign-change corresponds to a pole of \( f(x) \).

IFAIL= 4
Indicates that a serious error has occurred in C05AZF(*). Check all routine calls. Seek expert help.

7. Accuracy
This depends on the value of EPS and ETA. If full machine accuracy is required, they may be set very small, resulting in an error exit with IFAIL = 2, although this may involve more iterations than a lesser accuracy. The user is recommended to set ETA = 0.0 and to use EPS to control the accuracy, unless he has considerable knowledge of the size of \( f(x) \) for values of \( x \) near the zero.

8. Further Comments
The time taken by the routine depends primarily on the time spent evaluating \( F \) (see Section 5).

If it is important to determine an interval of length less than EPS containing the zero, or if the function \( F \) is expensive to evaluate and the number of calls to \( F \) is to be restricted, then use of C05AZF(*) is recommended. Use of C05AZF(*) is also recommended when the structure of the problem to be solved does not permit a simple function \( F \) to be written: the reverse communication facilities of C05AZF(*) are more flexible than the direct communication of \( F \) required by C05ADF.

9. Example

\[-x\]

The example program below calculates the zero of \( e^{-x} \) within the interval \([0,1]\) to approximately 5 decimal places.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
Solution of a system of nonlinear equations

C05NBF is an easy-to-use routine to find a solution of a system of nonlinear equations by a modification of the Powell hybrid method.

1. Purpose

C05NBF is an easy-to-use routine to find a solution of a system of nonlinear equations by a modification of the Powell hybrid method.

2. Specification

SUBROUTINE C05NBF (FCN, N, X, FVEC, XTOL, WA, LWA, IFAIL)
INTEGER N, LWA, IFAIL
EXTERNAL FCN

3. Description

The system of equations is defined as:

\[ f(x_1, x_2, \ldots, x_n) = 0, \text{ for } i=1,2,\ldots,n. \]
C05NBF is based upon the MINPACK routine HYBRD1 (More et al [1]). It chooses the correction at each step as a convex combination of the Newton and scaled gradient directions. Under reasonable conditions this guarantees global convergence for starting points far from the solution and a fast rate of convergence. The Jacobian is updated by the rank-1 method of Broyden. At the starting point the Jacobian is approximated by forward differences, but these are not used again until the rank-1 method fails to produce satisfactory progress. For more details see Powell [2].

4. References

5. Parameters

1: FCN -- SUBROUTINE, supplied by the user.

External Procedure
FCN must return the values of the functions \( f \) at a point \( x \).

Its specification is:

```fortran
SUBROUTINE FCN (N, X, FVEC, IFLAG)
INTEGER N, IFLAG
DOUBLE PRECISION X(N), FVEC(N)
```

1: N -- INTEGER Input
On entry: the number of equations, \( n \).

2: X(N) -- DOUBLE PRECISION array Input
On entry: the components of the point \( x \) at which the functions must be evaluated.

3: FVEC(N) -- DOUBLE PRECISION array Output
On exit: the function values \( f(x) \) (unless IFLAG is set to a negative value by FCN).

4: IFLAG -- INTEGER Input/Output
On entry: IFLAG > 0. On exit: in general, IFLAG should
not be reset by FCN. If, however, the user wishes to terminate execution (perhaps because some illegal point X has been reached), then IFLAG should be set to a negative integer. This value will be returned through IFAIL.

FCN must be declared as EXTERNAL in the (sub)program from which C05NBF is called. Parameters denoted as Input must not be changed by this procedure.

2: N -- INTEGER  
   On entry: the number of equations, n.  Constraint: N > 0.

3: X(N) -- DOUBLE PRECISION array  
   On entry: an initial guess at the solution vector. On exit: the final estimate of the solution vector.

4: FVEC(N) -- DOUBLE PRECISION array  
   On exit: the function values at the final point, X.

5: XTOL -- DOUBLE PRECISION  
   On entry: the accuracy in X to which the solution is required. Suggested value: the square root of the machine precision. Constraint: XTOL >= 0.0.

6: WA(LWA) -- DOUBLE PRECISION array  
   Workspace

7: LWA -- INTEGER  

8: IFAIL -- INTEGER  
   On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
   On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL< 0
The user has set IFLAG negative in FCN. The value of IFAIL will be the same as the user's setting of IFLAG.

IFAIL= 1
On entry $N \leq 0,$
or $XTOL < 0.0,$
or $LWA < N^*(3N+13)/2.$

IFAIL = 2
There have been at least $200*(N+1)$ evaluations of FCN.
Consider restarting the calculation from the final point held in $X.$

IFAIL = 3
No further improvement in the approximate solution $X$ is possible; $XTOL$ is too small.

IFAIL = 4
The iteration is not making good progress. This failure exit may indicate that the system does not have a zero, or that the solution is very close to the origin (see Section 7). Otherwise, rerunning C05NBF from a different starting point may avoid the region of difficulty.

7. Accuracy

If $x$ is the true solution, C05NBF tries to ensure that

$$||x-x|| \leq XTOL*||x||.$$ 

If this condition is satisfied with $XTOL = 10^{-k},$ then the larger components of $x$ have $k$ significant decimal digits. There is a danger that the smaller components of $x$ may have large relative errors, but the fast rate of convergence of C05NBF usually avoids this possibility.

If $XTOL$ is less than machine precision, and the above test is satisfied with the machine precision in place of $XTOL,$ then the routine exits with IFAIL = 3.

Note: this convergence test is based purely on relative error, and may not indicate convergence if the solution is very close to the origin.

The test assumes that the functions are reasonably well behaved. If this condition is not satisfied, then C05NBF may incorrectly indicate convergence. The validity of the answer can be checked, for example, by rerunning C05NBF with a tighter tolerance.
8. Further Comments

The time required by C05NBF to solve a given problem depends on n, the behaviour of the functions, the accuracy requested and the starting point. The number of arithmetic operations executed by C05NBF to process each call of FCN is about 11.5*n. Unless FCN can be evaluated quickly, the timing of C05NBF will be strongly influenced by the time spent in FCN.

Ideally the problem should be scaled so that at the solution the function values are of comparable magnitude.

9. Example

To determine the values x₁,..., x₉ which satisfy the tridiagonal equations:

\[
\begin{align*}
(3-2x)_{11} x_{12} - 2x_1 &= -1 \\
-x_{1i} + (3-2x)_{i2} x_{i3} - 2x_i &= -1, \quad i=2,3,...,8 \\
-x_{89} + (3-2x)_{99} x_9 &= -1.
\end{align*}
\]

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
The system of equations is defined as:

\[ f(x_i, x_2, \ldots, x_n) = 0, \quad i = 1, 2, \ldots, n. \]

C05PBF is based upon the MINPACK routine HYBRJ1 (More et al [1]). It chooses the correction at each step as a convex combination of the Newton and scaled gradient directions. Under reasonable conditions this guarantees global convergence for starting points far from the solution and a fast rate of convergence. The Jacobian is updated by the rank-1 method of Broyden. At the starting point the Jacobian is calculated, but it is not recalculated until the rank-1 method fails to produce satisfactory progress. For more details see Powell [2].

4. References

5. Parameters

1: FCN -- SUBROUTINE, supplied by the user.

External Procedure

Depending upon the value of IFLAG, FCN must either return
the values of the functions \( f_i \) at a point \( x \) or return the
Jacobian at \( x \).

Its specification is:

```fortran
SUBROUTINE FCN (N, X, FVEC, FJAC, LDFJAC, IFLAG)
INTEGER N, LDFJAC, IFLAG
DOUBLE PRECISION X(N), FVEC(N), FJAC(LDFJAC,N)

1: N -- INTEGER
Input
On entry: the number of equations, \( n \).

2: X(N) -- DOUBLE PRECISION array
Input
On entry: the components of the point \( x \) at which the
functions or the Jacobian must be evaluated.

3: FVEC(N) -- DOUBLE PRECISION array
Output
On exit: if IFLAG = 1 on entry, FVEC must contain the
function values \( f_i (x) \) (unless IFLAG is set to a
negative value by FCN). If IFLAG = 2 on entry, FVEC
must not be changed.

4: FJAC(LDFJAC,N) -- DOUBLE PRECISION array
Output
On exit: if IFLAG = 2 on entry, FJAC(i,j) must contain
\( \frac{df_i}{dx_j} \) (unless IFLAG is set to a negative value by FCN).

If IFLAG = 1 on entry, FJAC must not be changed.

5: LDFJAC -- INTEGER
Input
On entry: the first dimension of FJAC.

6: IFLAG -- INTEGER
Input/Output
On entry: IFLAG = 1 or 2:
if IFLAG = 1, FVEC is to be updated;

if IFLAG = 2, FJAC is to be updated.

On exit: in general, IFLAG should not be reset by FCN.
If, however, the user wishes to terminate execution
(perhaps because some illegal point x has been reached)
then IFLAG should be set to a negative integer. This
value will be returned through IFAIL.

FCN must be declared as EXTERNAL in the (sub)program
from which C05PBF is called. Parameters denoted as
Input must not be changed by this procedure.

2: N -- INTEGER Input
On entry: the number of equations, n. Constraint: N > 0.

3: X(N) -- DOUBLE PRECISION array Input/Output
On entry: an initial guess at the solution vector. On
exit: the final estimate of the solution vector.

4: FVEC(N) -- DOUBLE PRECISION array Output
On exit: the function values at the final point, X.

5: FJAC(LDFJAC,N) -- DOUBLE PRECISION array Output
On exit: the orthogonal matrix Q produced by the QR
factorization of the final approximate Jacobian.

6: LDFJAC -- INTEGER Input
On entry: the first dimension of the array FJAC as declared in the
(sub)program from which C05PBF is called.
Constraint: LDFJAC >= N.

7: XTOL -- DOUBLE PRECISION Input
On entry: the accuracy in X to which the solution is
required. Suggested value: the square root of the machine
precision. Constraint: XTOL >= 0.0.

8: WA(LWA) -- DOUBLE PRECISION array Workspace

9: LWA -- INTEGER Input
On entry: the dimension of the array WA. Constraint:
LWA>=N*(N+13)/2.

10: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not
familiar with this parameter (described in the Essential
Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see
Section 6).
6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL< 0
   A negative value of IFAIL indicates an exit from C05PBF because the user has set IFLAG negative in FCN. The value of IFAIL will be the same as the user’s setting of IFLAG.

IFAIL= 1
   On entry N <= 0,
   or LDFJAC < N,
   or XTOL < 0.0,
   or LWA<N*(N+13)/2.

IFAIL= 2
   There have been 100*(N+1) evaluations of the functions. Consider restarting the calculation from the final point held in X.

IFAIL= 3
   No further improvement in the approximate solution X is possible; XTOL is too small.

IFAIL= 4
   The iteration is not making good progress. This failure exit may indicate that the system does not have a zero or that the solution is very close to the origin (see Section 7). Otherwise, rerunning C05PBF from a different starting point may avoid the region of difficulty.

7. Accuracy

If x is the true solution, C05PBF tries to ensure that

\[ ||x-x|| \leq XTOL*||x|| \cdot 2 \]

-^k

If this condition is satisfied with XTOL=10^-^k, then the larger components of x have k significant decimal digits. There is a
danger that the smaller components of $x$ may have large relative errors, but the fast rate of convergence of C05PBF usually avoids the possibility.

If XTOL is less than machine precision and the above test is satisfied with the machine precision in place of XTOL, then the routine exits with IFAIL = 3.

Note: this convergence test is based purely on relative error, and may not indicate convergence if the solution is very close to the origin.

The test assumes that the functions and Jacobian are coded consistently and that the functions are reasonably well behaved. If these conditions are not satisfied then C05PBF may incorrectly indicate convergence. The coding of the Jacobian can be checked using C05ZAF. If the Jacobian is coded correctly, then the validity of the answer can be checked by rerunning C05PBF with a tighter tolerance.

8. Further Comments

The time required by C05PBF to solve a given problem depends on $n$, the behaviour of the functions, the accuracy requested and the starting point. The number of arithmetic operations executed by C05PBF is about $11.5n^2$ to process each evaluation of the functions and about $1.3n^3$ to process each evaluation of the Jacobian. Unless FCN can be evaluated quickly, the timing of C05PBF will be strongly influenced by the time spent in FCN.

Ideally the problem should be scaled so that, at the solution, the function values are of comparable magnitude.

9. Example

To determine the values $x_1,\ldots, x_9$ which satisfy the tridiagonal equations:

\[
\begin{align*}
(3-2x_1)x_1 - 2x_1 &= -1, \\
(3-2x_2)x_2 - 2x_2 &= -1, \ i=2,3,\ldots,8, \\
(3-2x_9)x_9 &= -1.
\end{align*}
\]
The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

Checks the gradients of a set of non-linear functions

--- nagc.ht ---

1. Purpose

C05ZAF checks the user-provided gradients of a set of non-linear functions in several variables, for consistency with the functions themselves. The routine must be called twice.

2. Specification

```fortran
SUBROUTINE C05ZAF (M, N, X, FVEC, FJAC, LDFJAC, XP, FVECP, 1 MODE, ERR)
INTEGER M, N, LDFJAC, MODE
DOUBLE PRECISION X(N), FVEC(M), FJAC(LDFJAC,N), XP(N), 1 FVECP(M), ERR(M)
```

3. Description

---

---
C05ZAF is based upon the MINPACK routine CHKDER (More et al [1]). It checks the ith gradient for consistency with the ith function by computing a forward-difference approximation along a suitably chosen direction and comparing this approximation with the user-supplied gradient along the same direction. The principal characteristic of C05ZAF is its invariance under changes in scale of the variables or functions.

4. References

5. Parameters

1: M -- INTEGER Input
   On entry: the number of functions.

2: N -- INTEGER Input
   On entry: the number of variables. For use with C05PBF and C05PCF(*), M = N.

3: X(N) -- DOUBLE PRECISION array Input
   On entry: the components of a point x, at which the consistency check is to be made. (See Section 8.)

4: FVEC(M) -- DOUBLE PRECISION array Input
   On entry: when MODE = 2, FVEC must contain the functions evaluated at x.

5: FJAC(LDFJAC,N) -- DOUBLE PRECISION array Input
   On entry: when MODE = 2, FJAC must contain the user-supplied gradients. (The ith row of FJAC must contain the gradient of the ith function evaluated at the point x.)

6: LDFJAC -- INTEGER Input
   On entry: the first dimension of the array FJAC as declared in the (sub)program from which C05ZAF is called.
   Constraint: LDFJAC >= M.

7: XP(N) -- DOUBLE PRECISION array Output
   On exit: when MODE = 1, XP is set to a neighbour point to X.

8: FVECP(M) -- DOUBLE PRECISION array Input
   On entry: when MODE = 2, FVECP must contain the functions evaluated at XP.

9:  MODE -- INTEGER  Input
    On entry: the value 1 on the first call and the value 2 on
    the second call of C05ZAF.

10: ERR(M) -- DOUBLE PRECISION  array  Output
    On exit: when MODE = 2, ERR contains measures of
    correctness of the respective gradients. If there is no loss
    of significance (see Section 8), then if ERR(i) is 1.0 the i
    th user-supplied gradient is correct, whilst if ERR(i) is 0.
    0 the ith gradient is incorrect. For values of ERR(i)
    between 0.0 and 1.0 the categorisation is less certain. In
    general, a value of ERR(i)>0.5 indicates that the ith
    gradient is probably correct.

6. Error Indicators and Warnings

   None.

7. Accuracy

   See below.

8. Further Comments

   The time required by C05ZAF increases with M and N.

   C05ZAF does not perform reliably if cancellation or rounding
   errors cause a severe loss of significance in the evaluation of a
   function. Therefore, none of the components of x should be
   unusually small (in particular, zero) or any other value which
   may cause loss of significance. The relative differences between
   corresponding elements of FVECP and FVEC should be at least two
   orders of magnitude greater than the machine precision.

9. Example

   This example checks the Jacobian matrix for a problem with 15
   functions of 3 variables. The results indicate that the first 7
   gradients are probably incorrect (this is caused by a deliberate
   error in the code to calculate the Jacobian).

   The example program is not reproduced here. The source code for
   all example programs is distributed with the NAG Foundation
   Library software and should be available on-line.
Discrete Fourier transform of real or complex data values

--- nagc.ht ---

C06(3NAG) Foundation Library (12/10/92) C06(3NAG)

C06 -- Summation of Series

Chapter C06

Summation of Series

1. Scope of the Chapter

This chapter is concerned with calculating the discrete Fourier transform of a sequence of real or complex data values, and applying it to calculate convolutions and correlations.

2. Background to the Problems

2.1. Discrete Fourier Transforms

2.1.1. Complex transforms

Most of the routines in this chapter calculate the finite discrete Fourier transform (DFT) of a sequence of n complex numbers \( z_j \), for \( j=0,1,...,n-1 \). The transform is defined by:

\[
\hat{z}_k = \frac{1}{\sqrt{n}} \sum_{j=0}^{n-1} z_j e^{-2\pi i jk/n}, \quad k=0,1,\ldots,n-1.
\]

for \( k=0,1,\ldots,n-1 \). Note that equation (1) makes sense for all integral \( k \) and with this extension \( z_k \) is periodic with period \( n \),
i.e. \( z = z \), and in particular \( z = z \).

\[
\begin{align*}
\text{If we write } z &= x + iy \text{ and } z = a + ib, \text{ then the definition of } z \\
\text{may be written in terms of sines and cosines as:}
\end{align*}
\]

\[
\begin{align*}
&\text{for } j=0,1,\ldots,n-1. \text{ If we take the complex conjugate of (2), we}
\end{align*}
\]

\[
\text{find that the sequence } z \text{ is the DFT of the sequence } z. \text{ Hence}
\]

\[
\text{the inverse DFT of the sequence } z \text{ may be obtained by: taking the}
\]

\[
\text{complex conjugates of the } z; \text{ performing a DFT; and taking the}
\]

\[
\text{complex conjugates of the result.}
\]

Notes: definitions of the discrete Fourier transform vary. Sometimes (2) is used as the definition of the DFT, and (1) as
the definition of the inverse. Also the scale-factor of $1/\sqrt{n}$ may be omitted in the definition of the DFT, and replaced by $1/n$ in the definition of the inverse.

2.1.2. Real transforms

If the original sequence is purely real valued, i.e. $z = x$, then

$$
\begin{align*}
\sum_{j=0}^{n-1} z \exp\left(-i \frac{2\pi jk}{n}\right)
\end{align*}
$$

and $z$ is the complex conjugate of $z$. Thus the DFT of a real sequence is a particular type of complex sequence, called a Hermitian sequence, or half-complex or conjugate symmetric with the properties:

- $a = a$
- $b = -b$
- $b = 0$ and, if $n$ is even, $b = 0$.

Thus a Hermitian sequence of $n$ complex data values can be represented by only $n$, rather than $2n$, independent real values. This can obviously lead to economies in storage, the following scheme being used in this chapter: the real parts $a$ for $0 \leq k < n/2$ are stored in normal order in the first $n/2 + 1$ locations of an array $X$ of length $n$; the corresponding non-zero imaginary parts are stored in reverse order in the remaining locations of $X$. In other words, if $X$ is declared with bounds $(0:n-1)$ in the user's (sub)program, the real and imaginary parts of $z$ are stored as follows:

<table>
<thead>
<tr>
<th></th>
<th>$k$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$X(0)$</td>
<td>a</td>
</tr>
<tr>
<td></td>
<td>0</td>
</tr>
<tr>
<td>$X(1)$</td>
<td>a</td>
</tr>
<tr>
<td></td>
<td>1</td>
</tr>
<tr>
<td>$X(2)$</td>
<td>a</td>
</tr>
<tr>
<td></td>
<td>2</td>
</tr>
</tbody>
</table>
X(s-1) a a
   s-1 s-1
X(s)   a b
   s s-1
X(s+1) b b
   s-1 s-2
   . .
   . .
   . .
X(n-2) b b
   2 2
X(n-1) b b
   1 1

\[ x = \frac{1}{\sqrt{n}} \left( \sum_{k=0}^{n/2-1} a \cos \left( \frac{2\pi jk}{n} \right) - b \sin \left( \frac{2\pi jk}{n} \right) \right) + a \]

where \( a = 0 \) if \( n \) is odd.

2.1.3. Fourier integral transforms

The usual application of the discrete Fourier transform is that of obtaining an approximation of the Fourier integral transform

\[ F(s) = \int_{-\infty}^{+\infty} f(t) \exp(-i2\pi st) dt \]

when \( f(t) \) is negligible outside some region \((0,c)\). Dividing the
region into \( n \) equal intervals we have

\[
F(s) = \sum_{j=0}^{n-1} f(jc/n) \exp(-i2\pi sjc/n)
\]

and so

\[
F(k) = \sum_{j=0}^{n-1} f(jc/n) \exp(-i2\pi jk/n)
\]

for \( k=0,1,\ldots,n-1 \), where \( f = f(jc/n) \) and \( F = F(k/c) \).

Hence the discrete Fourier transform gives an approximation to
the Fourier integral transform in the region \( s=0 \) to \( s=n/c \).

If the function \( f(t) \) is defined over some more general interval
\((a,b)\), then the integral transform can still be approximated by
the discrete transform provided a shift is applied to move the
point \( a \) to the origin.

2.1.4. Convolutions and correlations

One of the most important applications of the discrete Fourier
transform is to the computation of the discrete convolution or
correlation of two vectors \( x \) and \( y \) defined (as in Brigham [1])
by:

\[
\text{convolution: } z(k) = \sum_{j=0}^{n-1} x(j) y(k-j)
\]

\[
\text{correlation: } w(k) = \sum_{j=0}^{n-1} x(j) y(k+j)
\]

(Here \( x \) and \( y \) are assumed to be periodic with period \( n \).)

Under certain circumstances (see Brigham [1]) these can be used
as approximations to the convolution or correlation integrals
defined by:
\[
\begin{align*}
+\infty & \quad / \\
-\infty & \quad z(s) = \int_{-\infty}^{+\infty} x(t)y(s-t)dt \\
-\infty & \quad / \\
\end{align*}
\]
and
\[
\begin{align*}
+\infty & \quad / \\
-\infty & \quad w(s) = \int_{-\infty}^{+\infty} x(t)y(s+t)dt, \quad -\infty < s < +\infty. \\
-\infty & \quad / \\
\end{align*}
\]
For more general advice on the use of Fourier transforms, see Hamming [2]; more detailed information on the fast Fourier transform algorithms can be found in Van Loan [3] and Brigham [1].

2.2. References

3. Recommendations on Choice and Use of Routines

3.1. One-dimensional Fourier Transforms

The choice of routine is determined first of all by whether the data values constitute a real, Hermitian or general complex sequence. It is wasteful of time and storage to use an inappropriate routine.

Two groups, each of three routines, are provided

<table>
<thead>
<tr>
<th>Group 1</th>
<th>Group 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Real sequences</td>
<td>C06EAF</td>
</tr>
<tr>
<td>Hermitian</td>
<td>C06FBF</td>
</tr>
<tr>
<td>General complex</td>
<td>C06ECF</td>
</tr>
<tr>
<td>sequences</td>
<td>C06FRF</td>
</tr>
</tbody>
</table>
Group 1 routines each compute a single transform of length \( n \), without requiring any extra working storage. The Group 1 routines impose some restrictions on the value of \( n \), namely that no prime factor of \( n \) may exceed 19 and the total number of prime factors (including repetitions) may not exceed 20 (though the latter restriction only becomes relevant when \( n > 10 \)).

Group 2 routines are designed to perform several transforms in a single call, all with the same value of \( n \). They do however require more working storage. Even on scalar processors, they may be somewhat faster than repeated calls to Group 1 routines because of reduced overheads and because they pre-compute and store the required values of trigonometric functions. Group 2 routines impose no practical restrictions on the value of \( n \); however the fast Fourier transform algorithm ceases to be 'fast' if applied to values of \( n \) which cannot be expressed as a product of small prime factors. All the above routines are particularly efficient if the only prime factors of \( n \) are 2, 3 or 5.

If extensive use is to be made of these routines, users who are concerned about efficiency are advised to conduct their own timing tests.

To compute inverse discrete Fourier transforms the above routines should be used in conjunction with the utility routines C06GBF, C06GCF and C06GQF which form the complex conjugate of a Hermitian or general sequence of complex data values.

### 3.2. Multi-dimensional Fourier Transforms

C06FUF computes a 2-dimensional discrete Fourier transform of a 2-dimensional sequence of complex data values. This is defined by

\[
\begin{align*}
\begin{bmatrix}
1 & 2 \\
1 & \quad \\
\end{bmatrix}
\begin{bmatrix}
2 \pi j k \\
1 \\
\end{bmatrix}
\begin{bmatrix}
2 \pi j k \\
1 \\
\end{bmatrix}
\end{align*}
\]

\[
\begin{bmatrix}
1 & 2 \\
\end{bmatrix}
\begin{bmatrix}
\frac{1}{n} \\
\frac{1}{n} \\
\end{bmatrix}
\begin{bmatrix}
\frac{2}{2} \\
\end{bmatrix}
\]

\[
\begin{bmatrix}
k & k \\
1 & \quad \\
\end{bmatrix}
\begin{bmatrix}
j = 0 \\
\quad \\
\end{bmatrix}
\begin{bmatrix}
j = 0 \\
\quad \\
\end{bmatrix}
\]

\[
\begin{bmatrix}
1 & 2 \\
1 & \quad \\
\end{bmatrix}
\begin{bmatrix}
1 \\
2 \\
\end{bmatrix}
\begin{bmatrix}
1 \\
2 \\
\end{bmatrix}
\]

### 3.3. Convolution and Correlation

C06EKF computes either the discrete convolution or the discrete correlation of two real vectors.

Discrete Fourier transform of n real data values

Given a sequence of n real data values \( x_j \), for \( j=0,1,\ldots,n-1, \)
this routine calculates their discrete Fourier transform defined by:

\[ z_k = \sum_{j=0}^{n-1} x_j \exp\left(-\frac{2\pi i j k}{n}\right), \quad k=0,1,\ldots,n-1. \]

(Note the scale factor of \(\frac{1}{\sqrt{n}}\) in this definition.) The transformed values \(z\) are complex, but they form a Hermitian sequence (i.e., \(z_k\) is the complex conjugate of \(z_{n-k}\)), so they are completely determined by \(n\) real numbers (see also the Chapter Introduction).

To compute the inverse discrete Fourier transform defined by:

\[ w_k = \sum_{j=0}^{n-1} x_j \exp\left(+\frac{2\pi i j k}{n}\right), \quad k=0,1,\ldots,n-1, \]

this routine should be followed by a call of C06GBF to form the complex conjugates of the \(z\).

The routine uses the fast Fourier transform (FFT) algorithm (Brigham [1]). There are some restrictions on the value of \(n\) (see Section 5).

4. References

5. Parameters

1: \(X(n)\) -- DOUBLE PRECISION array Input/Output

On entry: if \(X\) is declared with bounds (0:N-1) in the (sub) program from which C06EAF is called, then \(X(j)\) must contain
x, for \( j = 0, 1, \ldots, n-1 \). On exit: the discrete Fourier transform stored in Hermitian form. If the components of the transform \( z \) are written as \( a + ib \), and if \( X \) is declared with bounds \( 0: N-1 \) in the (sub)program from which C06EAF is called, then for \( 0 \leq k \leq n/2 \), \( a \) is contained in \( X(k) \), and for \( 1 \leq k \leq (n-1)/2 \), \( b \) is contained in \( X(n-k) \). (See also Section 2.1.2 of the Chapter Introduction, and the Example Program.)

2: \( N \) -- INTEGER Input
On entry: the number of data values, \( n \). The largest prime factor of \( N \) must not exceed 19, and the total number of prime factors of \( N \), counting repetitions, must not exceed 20. Constraint: \( N > 1 \).

3: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
At least one of the prime factors of \( N \) is greater than 19.

IFAIL= 2
\( N \) has more than 20 prime factors.

IFAIL= 3
\( N \leq 1 \).

7. Accuracy

Some indication of accuracy can be obtained by performing a subsequent inverse transform and comparing the results with the original sequence (in exact arithmetic they would be identical).

8. Further Comments

The time taken by the routine is approximately proportional to \( n \cdot \log n \), but also depends on the factorization of \( n \). The routine
is somewhat faster than average if the only prime factors of n are 2, 3 or 5; and fastest of all if n is a power of 2.

On the other hand, the routine is particularly slow if n has several unpaired prime factors, i.e., if the 'square-free' part of n has several factors. For such values of n, routine C06FAF(*) (which requires an additional n elements of workspace) is considerably faster.

9. Example

This program reads in a sequence of real data values, and prints their discrete Fourier transform (as computed by C06EAF), after expanding it from Hermitian form into a full complex sequence.

It then performs an inverse transform using C06GBF and C06EBF, and prints the sequence so obtained alongside the original data values.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

Discrete Fourier transform of a Hermitian sequence

— nagc.ht —

Note: Before using this routine, please read the Users’ Note for
your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

C06EBF calculates the discrete Fourier transform of a Hermitian sequence of n complex data values. (No extra workspace required.)

2. Specification

SUBROUTINE C06EBF (X, N, IFAIL)
INTEGER N, IFAIL
DOUBLE PRECISION X(N)

3. Description

Given a Hermitian sequence of n complex data values $z_j$ (i.e., a sequence such that $z_j$ is real and $z_j^*$ is the complex conjugate of $z_j$, for $j=1,2,...,n-1$) this routine calculates their discrete Fourier transform defined by:

$$
x_k = \frac{1}{\sqrt{n}} \sum_{j=0}^{n-1} z_j \exp\left(\frac{-2\pi i j k}{n}\right), \quad k=0,1,...,n-1.
$$

(Note the scale factor of $\frac{1}{\sqrt{n}}$ in this definition.) The transformed values $x_k$ are purely real (see also the Chapter Introduction).

To compute the inverse discrete Fourier transform defined by:

$$
y_k = \frac{1}{\sqrt{n}} \sum_{j=0}^{n-1} z_j \exp\left(\frac{2\pi i j k}{n}\right), \quad k=0,1,...,n-1,
$$

this routine should be preceded by a call of C06GBF to form the
complex conjugates of the $z_j$.

The routine uses the fast Fourier transform (FFT) algorithm (Brigham [1]). There are some restrictions on the value of $n$ (see Section 5).

4. References

5. Parameters

1: $X(N)$ -- DOUBLE PRECISION array Input/Output
   On entry: the sequence to be transformed stored in Hermitian form. If the data values $z_j$ are written as $x + iy_j$ and if $X$ is declared with bounds $(0:N-1)$ in the subroutine from which C06EBF is called, then for $0 \leq j \leq n/2$, $x_j$ is contained in $X(j)$, and for $1 \leq j \leq (n-1)/2$, $y_j$ is contained in $X(n-j)$. (See also Section 2.1.2 of the Chapter Introduction and the Example Program.) On exit: the components of the discrete Fourier transform $x_k$. If $X$ is declared with bounds $(0:N-1)$ in the (sub)program from which C06EBF is called, then $x_k$ is stored in $X(k)$, for $k=0,1,...,n-1$.

2: $N$ -- INTEGER Input
   On entry: the number of data values, $n$. The largest prime factor of $N$ must not exceed 19, and the total number of prime factors of $N$, counting repetitions, must not exceed 20. Constraint: $N > 1$.

3: IFAIL -- INTEGER Input/Output
   On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

   On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:
22.2. NAGC.HT

IFAIL= 1
At least one of the prime factors of N is greater than 19.

IFAIL= 2
N has more than 20 prime factors.

IFAIL= 3
N <= 1.

7. Accuracy

Some indication of accuracy can be obtained by performing a subsequent inverse transform and comparing the results with the original sequence (in exact arithmetic they would be identical).

8. Further Comments

The time taken by the routine is approximately proportional to n*\log n, but also depends on the factorization of n. The routine is somewhat faster than average if the only prime factors of n are 2, 3 or 5; and fastest of all if n is a power of 2.

On the other hand, the routine is particularly slow if n has several unpaired prime factors, i.e., if the 'square-free' part of n has several factors. For such values of n, routine C06FBF(*) (which requires an additional n elements of workspace) is considerably faster.

9. Example

This program reads in a sequence of real data values which is assumed to be a Hermitian sequence of complex data values stored in Hermitian form. The input sequence is expanded into a full complex sequence and printed alongside the original sequence. The discrete Fourier transform (as computed by C06EBF) is printed out.

The program then performs an inverse transform using C06EAF and C06GBF, and prints the sequence so obtained alongside the original data values.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

Introduction) the recommended value is 0.

On exit: \( IFAIL = 0 \) unless the routine detects an error (see
Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL = 1
At least one of the prime factors of \( N \) is greater than 19.

IFAIL = 2
\( N \) has more than 20 prime factors.

IFAIL = 3
\( N \leq 1 \).

7. Accuracy

Some indication of accuracy can be obtained by performing a
subsequent inverse transform and comparing the results with the
original sequence (in exact arithmetic they would be identical).

8. Further Comments

The time taken by the routine is approximately proportional to
\( n \log N \), but also depends on the factorization of \( n \). The routine
is somewhat faster than average if the only prime factors of \( n \)
are 2, 3 or 5; and fastest of all if \( n \) is a power of 2.

On the other hand, the routine is particularly slow if \( n \) has
several unpaired prime factors, i.e., if the 'square-free' part
of \( n \) has several factors. For such values of \( n \), routine C06FCF(*)
(which requires an additional \( n \) real elements of workspace) is
considerably faster.
9. Example

This program reads in a sequence of complex data values and prints their discrete Fourier transform.

It then performs an inverse transform using C06GCF and C06ECF, and prints the sequence so obtained alongside the original data values.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

Circular convolution or correlation of two real vectors

--- nagc.ht ---

C06EKF(3NAG) Foundation Library (12/10/92) C06EKF(3NAG)

C06 -- Summation of Series

C06EKF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

C06EKF calculates the circular convolution or correlation of two real vectors of period n. No extra workspace is required.

2. Specification
3. Description

This routine computes:

if JOB = 1, the discrete convolution of x and y, defined by:

\[
\begin{align*}
    z_k &= \sum_{j=0}^{n-1} x_{k-j} y_j \\
    &= \sum_{j=0}^{n-1} x_j y_{k-j}
\end{align*}
\]

if JOB = 2, the discrete correlation of x and y defined by:

\[
\begin{align*}
    w_k &= \sum_{j=0}^{n-1} x_j y_{k+j}
\end{align*}
\]

Here x and y are real vectors, assumed to be periodic, with period n, i.e., x = x = x = ...; z and w are then also periodic with period n.

Note: this usage of the terms 'convolution' and 'correlation' is taken from Brigham [1]. The term 'convolution' is sometimes used to denote both these computations.

If x, y, z and w are the discrete Fourier transforms of these sequences,

\[
\begin{align*}
    x_k &= \frac{1}{n} \sum_{j=0}^{n-1} x_j \exp(-2\pi i jk/n) \\
    &= \frac{1}{n} \sum_{j=0}^{n-1} x_j \exp(-2\pi jk/n)
\end{align*}
\]

then 

\[
\begin{align*}
    z_k &= x_k y_k
\end{align*}
\]
22.2. **NAGC.HT**

and \( w = \overline{n.x.y} \)

(the bar denoting complex conjugate).

This routine calls the same auxiliary routines as C06EAF and C06EBF to compute discrete Fourier transforms, and there are some restrictions on the value of \( n \).

4. References

5. Parameters

1: JOB -- INTEGER Input
   On entry: the computation to be performed:
   \[ n-1 \]
   --
   if JOB = 1, \( z = x.y \) (convolution);
   \[ k -- j \]
   \[ k -- j \]
   \[ j=0 \]
   \[ n-1 \]
   --
   if JOB = 2, \( w = x.y \) (correlation).
   \[ k -- j \]
   \[ j=0 \]

Constraint: JOB = 1 or 2.

2: X(N) -- DOUBLE PRECISION array Input/Output
   On entry: the elements of one period of the vector \( x \). If \( X \)
   is declared with bounds (0:N-1) in the (sub)program from
   which C06EKF is called, then \( X(j) \) must contain \( x(j) \), for
   \[ j=0,1,...,n-1 \]. On exit: the corresponding elements of the
   discrete convolution or correlation.

3: Y(N) -- DOUBLE PRECISION array Input/Output
   On entry: the elements of one period of the vector \( y \). If \( Y \)
   is declared with bounds (0:N-1) in the (sub)program from
   which C06EKF is called, then \( Y(j) \) must contain \( y(j) \), for
   \[ j=0,1,...,n-1 \]. On exit: the discrete Fourier transform of
   the convolution or correlation returned in the array \( X \); the
   transform is stored in Hermitian form, exactly as described
   in the document C06EAF.
4: N -- INTEGER  
   On entry: the number of values, n, in one period of the 
   vectors X and Y. The largest prime factor of N must not 
   exceed 19, and the total number of prime factors of N, 

5: IFAIL -- INTEGER  
   On entry: IFAIL must be set to 0, -1 or 1. For users not 
   familiar with this parameter (described in the Essential 
   Introduction) the recommended value is 0.

   On exit: IFAIL = 0 unless the routine detects an error (see 
   Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
   At least one of the prime factors of N is greater than 19.

IFAIL= 2
   N has more than 20 prime factors.

IFAIL= 3
   N <= 1.

IFAIL= 4
   JOB /= 1 or 2.

7. Accuracy

The results should be accurate to within a small multiple of the 
machine precision.

8. Further Comments

The time taken by the routine is approximately proportional to 
n*logn, but also depends on the factorization of n. The routine 
is faster than average if the only prime factors are 2, 3 or 5; 
and fastest of all if n is a power of 2.

The routine is particularly slow if n has several unpaired prime 
factors, i.e., if the 'square free' part of n has several 
factors. For such values of n, routine C06FKF(*) is considerably 
 faster (but requires an additional workspace of n elements).

9. Example

This program reads in the elements of one period of two real
vectors \( x \) and \( y \) and prints their discrete convolution and correlation (as computed by C06EKF). In realistic computations the number of data values would be much larger.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
3. Description

Given $m$ sequences of $n$ real data values $x_j$, for $j=0,1,\ldots,n-1$; $p=1,2,\ldots,m$, this routine simultaneously calculates the Fourier transforms of all the sequences defined by:

$$
z_k = \frac{1}{\sqrt{n}} \sum_{j=0}^{n-1} x_j \exp(-i \frac{2\pi jk}{n}), \quad k=0,1,\ldots,n-1; \quad p=1,2,\ldots,m.
$$

(Note the scale factor $\frac{1}{\sqrt{n}}$ in this definition.)

The transformed values $z_k$ are complex, but for each value of $p$ the $z_k$ form a Hermitian sequence (i.e., $z_k$ is the complex conjugate of $z_{n-k}$), so they are completely determined by $mn$ real numbers (see also the Chapter Introduction).

The discrete Fourier transform is sometimes defined using a positive sign in the exponential term:

$$
z_k = \frac{1}{\sqrt{n}} \sum_{j=0}^{n-1} x_j \exp(+i \frac{2\pi jk}{n}), \quad k=0,1,\ldots,n-1; \quad p=1,2,\ldots,m.
$$

To compute this form, this routine should be followed by a call to C06GQF to form the complex conjugates of the $z_k$.

The routine uses a variant of the fast Fourier transform (FFT) algorithm (Brigham [1]) known as the Stockham self-sorting algorithm, which is described in Temperton [2]. Special coding is
provided for the factors 2, 3, 4, 5 and 6. This routine is
designed to be particularly efficient on vector processors, and
it becomes especially fast as M, the number of transforms to be
computed in parallel, increases.

4. References

Hall.

5. Parameters

1: M -- INTEGER Input
   On entry: the number of sequences to be transformed, m.
   Constraint: M >= 1.

2: N -- INTEGER Input
   On entry: the number of real values in each sequence, n.
   Constraint: N >= 1.

3: X(M,N) -- DOUBLE PRECISION array Input/Output
   On entry: the data must be stored in X as if in a two-
dimensional array of dimension (1:M,0:N-1); each of the m
   sequences is stored in a row of the array. In other words,
   if the data values of the pth sequence to be transformed are
   denoted by \( x_p^j \), for \( j = 0,1,...,n-1 \), then the mn elements of
   the array X must contain the values
   \[
   x_0,x_0,x_1,x_1,x_2,x_2,...,x_{n-1},x_{n-1},x_0,x_0,...,x_{n-1},x_{n-1}.
   \]
   On exit: the m discrete Fourier transforms stored as if in
   a two-dimensional array of dimension (1:M,0:N-1). Each of
   the m transforms is stored in a row of the array in
   Hermitian form, overwriting the corresponding original
   sequence. If the n components of the discrete Fourier
   transform \( z_p^k \) are written as \( a_k + ib_k \), then for \( 0 \leq k < n/2 \), a
   \[
   a_k = X(p,k), \quad b_k = \frac{1}{\sqrt{m}} X(p,n-k).
   \]
   contained in X(p,n-k). (See also Section 2.1.2 of the
   Chapter Introduction.)

4: INIT -- CHARACTER*1 Input
On entry: if the trigonometric coefficients required to compute the transforms are to be calculated by the routine and stored in the array TRIG, then INIT must be set equal to 'I' (Initial call).

If INIT contains 'S' (Subsequent call), then the routine assumes that trigonometric coefficients for the specified value of n are supplied in the array TRIG, having been calculated in a previous call to one of C06FPF, C06FQF or C06FRF.

If INIT contains 'R' (Restart then the routine assumes that trigonometric coefficients for the particular value of n are supplied in the array TRIG, but does not check that C06FPF, C06FQF or C06FRF have previously been called. This option allows the TRIG array to be stored in an external file, read in and re-used without the need for a call with INIT equal to 'I'. The routine carries out a simple test to check that the current value of n is consistent with the array TRIG. Constraint: INIT = 'I', 'S' or 'R'.

5: TRIG(2*N) -- DOUBLE PRECISION array Input/Output
On entry: if INIT = 'S' or 'R', TRIG must contain the required coefficients calculated in a previous call of the routine. Otherwise TRIG need not be set. On exit: TRIG contains the required coefficients (computed by the routine if INIT = 'I').

6: WORK(M*N) -- DOUBLE PRECISION array Workspace

7: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1
On entry M < 1.

IFAIL= 2
NAGC.HT

22.2. NAGC.HT

N < 1.

IFAIL= 3
   INIT is not one of 'I', 'S' or 'R'.

IFAIL= 4
   INIT = 'S', but none of C06FPF, C06FQF or C06FRF has
   previously been called.

IFAIL= 5
   INIT = 'S' or 'R', but the array TRIG and the current value
   of N are inconsistent.

7. Accuracy

Some indication of accuracy can be obtained by performing a
subsequent inverse transform and comparing the results with the
original sequence (in exact arithmetic they would be identical).

8. Further Comments

The time taken by the routine is approximately proportional to
nm*logn, but also depends on the factors of n. The routine is
fastest if the only prime factors of n are 2, 3 and 5, and is
particularly slow if n is a large prime, or has large prime
factors.

9. Example

This program reads in sequences of real data values and prints
their discrete Fourier transforms (as computed by C06FPF). The
Fourier transforms are expanded into full complex form using
C06GSF and printed. Inverse transforms are then calculated by
calling C06GQF followed by C06FQF showing that the original
sequences are restored.

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.

\end{page}
Discrete Fourier transforms of \( m \) Hermitian sequences

\[ x_{\ell} = \frac{1}{\sqrt{n}} \sum_{j=0}^{n-1} z_{\ell j} e^{-2\pi i \ell j / n}, \quad \ell = 0, 1, \ldots, n-1; \quad p = 1, 2, \ldots, m. \]

Given \( m \) Hermitian sequences of \( n \) complex data values \( z_{\ell j} \), for \( j = 0, 1, \ldots, n-1; \quad p = 1, 2, \ldots, m \), this routine simultaneously calculates the Fourier transforms of all the sequences defined by:

\[ x_{\ell} = \frac{1}{\sqrt{n}} \sum_{j=0}^{n-1} z_{\ell j} e^{-2\pi i \ell j / n}, \quad \ell = 0, 1, \ldots, n-1; \quad p = 1, 2, \ldots, m. \]

1. Purpose

C06FQF computes the discrete Fourier transforms of \( m \) Hermitian sequences, each containing \( n \) complex data values. This routine is designed to be particularly efficient on vector processors.

2. Specification

```fortran
SUBROUTINE C06FQF (M, N, X, INIT, TRIG, WORK, IFAIL)
INTEGER M, N, IFAIL
DOUBLE PRECISION X(M*N), TRIG(2*N), WORK(M*N)
CHARACTER*1 INIT
```

3. Description

Given \( m \) Hermitian sequences of \( n \) complex data values \( z_{\ell j} \), for \( j = 0, 1, \ldots, n-1; \quad p = 1, 2, \ldots, m \), this routine simultaneously calculates the Fourier transforms of all the sequences defined by:

\[ x_{\ell} = \frac{1}{\sqrt{n}} \sum_{j=0}^{n-1} z_{\ell j} e^{-2\pi i \ell j / n}, \quad \ell = 0, 1, \ldots, n-1; \quad p = 1, 2, \ldots, m. \]
(Note the scale factor \( \cdot \) in this definition.)

The transformed values are purely real (see also the Chapter Introduction).

The discrete Fourier transform is sometimes defined using a positive sign in the exponential term

\[
\text{\( x = \sum_{j=0}^{n-1} z \cdot \exp(i \cdot (2\pi j k)/n) \)}
\]

To compute this form, this routine should be preceded by a call to C06GQF to form the complex conjugates of the \( z \).

The routine uses a variant of the fast Fourier transform (FFT) algorithm (Brigham [1]) known as the Stockham self-sorting algorithm, which is described in Temperton [2]. Special code is included for the factors 2, 3, 4, 5 and 6. This routine is designed to be particularly efficient on vector processors, and it becomes especially fast as \( m \), the number of transforms to be computed in parallel, increases.

4: \texttt{INIT} -- CHARACTER*1 \hspace{1em} \text{Input}

On entry: if the trigonometric coefficients required to
compute the transforms are to be calculated by the routine
and stored in the array \texttt{TRIG}, then \texttt{INIT} must be set equal to
'I' (Initial call).

If \texttt{INIT} contains 'S' (Subsequent call), then the routine
assumes that trigonometric coefficients for the specified
value of \texttt{n} are supplied in the array \texttt{TRIG}, having been

calculated in a previous call to one of \texttt{C06FPF}, \texttt{C06FQF} or
\texttt{C06FRF}.

If \texttt{INIT} contains 'R' (Restart), then the routine assumes
that trigonometric coefficients for the particular value of
\texttt{N} are supplied in the array \texttt{TRIG}, but does not check that
\texttt{C06FPF}, \texttt{C06FQF} or \texttt{C06FRF} have previously been called. This
option allows the \texttt{TRIG} array to be stored in an external
file, read in and re-used without the need for a call with
\texttt{INIT} equal to 'I'. The routine carries out a simple test to
check that the current value of \texttt{n} is compatible with the
array \texttt{TRIG}. Constraint: \texttt{INIT} = 'I', 'S' or 'R'.

5: \texttt{TRIG(2*N)} -- DOUBLE PRECISION array \hspace{1em} \text{Input/Output}
On entry: if INIT = 'S' or 'R', TRIG must contain the required coefficients calculated in a previous call of the routine. Otherwise TRIG need not be set. On exit: TRIG contains the required coefficients (computed by the routine if INIT = 'I').

6: WORK(M*N) -- DOUBLE PRECISION array Workspace

7: IFAIL -- INTEGER Input/Output
   On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
   On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1
   On entry M < 1.

IFAIL= 2
   On entry N < 1.

IFAIL= 3
   On entry INIT is not one of 'I', 'S' or 'R'.

IFAIL= 4
   On entry INIT = 'S', but none of C06FPF, C06FQF and C06FRF has previously been called.

IFAIL= 5
   On entry INIT = 'S' or 'R', but the array TRIG and the current value of n are inconsistent.

7. Accuracy

Some indication of accuracy can be obtained by performing a subsequent inverse transform and comparing the results with the original sequence (in exact arithmetic they would be identical).

8. Further Comments

The time taken by the routine is approximately proportional to nm*logn, but also depends on the factors of n. The routine is
fastest if the only prime factors of \( n \) are 2, 3 and 5, and is particularly slow if \( n \) is a large prime, or has large prime factors.

9. Example

This program reads in sequences of real data values which are assumed to be Hermitian sequences of complex data stored in Hermitian form. The sequences are expanded into full complex form using C06GSF and printed. The discrete Fourier transforms are then computed (using C06FQF) and printed out. Inverse transforms are then calculated by calling C06FPF followed by C06GQF showing that the original sequences are restored.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
C06FRF computes the discrete Fourier transforms of \( m \) sequences, each containing \( n \) complex data values. This routine is designed to be particularly efficient on vector processors.

2. Specification

```fortran
SUBROUTINE C06FRF (M, N, X, Y, INIT, TRIG, WORK, IFAIL)
INTEGER M, N, IFAIL
DOUBLE PRECISION X(M*N), Y(M*N), TRIG(2*N), WORK(2*M*N)
CHARACTER*1 INIT
```

3. Description

Given \( m \) sequences of \( n \) complex data values \( z_j \), for \( j = 0,1,\ldots,n-1; j \) \( p = 1,2,\ldots,m \), this routine simultaneously calculates the Fourier transforms of all the sequences defined by:

\[
\left( \frac{2\pi}{n} \right)^{\frac{1}{2}} \sum_{j=0}^{n-1} z_j \exp \left( -i \frac{2\pi jk}{n} \right), \quad k = 0,1,\ldots,n-1; \quad p = 1,2,\ldots,m.
\]

(Note the scale factor \( \frac{1}{\sqrt{n}} \) in this definition.)

The discrete Fourier transform is sometimes defined using a positive sign in the exponential term

\[
\left( \frac{2\pi}{n} \right)^{\frac{1}{2}} \sum_{j=0}^{n-1} z_j \exp \left( i \frac{2\pi jk}{n} \right).
\]

To compute this form, this routine should be preceded and followed by a call of C06GCF to form the complex conjugates of \( z_j \) and \( \tilde{z}_k \).

The routine uses a variant of the fast Fourier transform (FFT) algorithm (Brigham [1]) known as the Stockham self-sorting algorithm, which is described in Temperton [2]. Special code is
provided for the factors 2, 3, 4, 5 and 6. This routine is
designed to be particularly efficient on vector processors, and
it becomes especially fast as \( m \), the number of transforms to be
computed in parallel, increases.

Hall.

5. Parameters

1: \( M \) -- INTEGER Input
   On entry: the number of sequences to be transformed, \( m \).
   Constraint: \( M \geq 1 \).

2: \( N \) -- INTEGER Input
   On entry: the number of complex values in each sequence, \( n \).
   Constraint: \( N \geq 1 \).

3: \( X(M,N) \) -- DOUBLE PRECISION array Input/Output
   On entry: the real and imaginary parts of the complex data
   must be stored in \( X \) and \( Y \) respectively as if in a two-
dimensional array of dimension \( (1:M,0:N-1) \); each of the \( m \)
sequences is stored in a row of each array. In other words,
if the real parts of the \( p \)th sequence to be transformed are
\( x_j \), for \( j=0,1,...,n-1 \), then the \( mn \) elements of
the array \( X \) must contain the values
\[
1 2 m 1 2 m 1 2 m \\
x, x, \ldots, x, x, x, \ldots, x, \ldots, x, x, \ldots, x
0 0 1 1 1 n-1 n-1 n-1
\]
   On exit: \( X \) and \( Y \) are overwritten by the real and imaginary
   parts of the complex transforms.

4: \( Y(M,N) \) -- DOUBLE PRECISION array Input/Output
   On entry: the real and imaginary parts of the complex data
   must be stored in \( X \) and \( Y \) respectively as if in a two-
dimensional array of dimension \( (1:M,0:N-1) \); each of the \( m \)
sequences is stored in a row of each array. In other words,
if the real parts of the \( p \)th sequence to be transformed are
\( x_j \), for \( j=0,1,...,n-1 \), then the \( mn \) elements of
the array \( Y \) must contain the values
\[
1 2 m 1 2 m 1 2 m \\
x, x, \ldots, x, x, x, \ldots, x, \ldots, x, x, \ldots, x
0 0 1 1 1 n-1 n-1 n-1
\]
   On exit: \( X \) and \( Y \) are overwritten by the real and imaginary
   parts of the complex transforms.

5: \( \text{INIT} \) -- CHARACTER*1 Input
   On entry: if the trigonometric coefficients required to
   compute the transforms are to be calculated by the routine
   and stored in the array TRIG, then \( \text{INIT} \) must be set equal to
   'I' (Initial call).
   If \( \text{INIT} \) contains 'S' (Subsequent call), then the routine
   assumes that trigonometric coefficients for the specified
   value of \( n \) are supplied in the array TRIG, having been
calculated in a previous call to one of C06FPF, C06FQF or C06FRF.

If INIT contains 'R' (Restart) then the routine assumes that trigonometric coefficients for the particular value of \( n \) are supplied in the array TRIG, but does not check that C06FPF, C06FQF or C06FRF have previously been called. This option allows the TRIG array to be stored in an external file, read in and re-used without the need for a call with INIT equal to 'I'. The routine carries out a simple test to check that the current value of \( n \) is compatible with the array TRIG. Constraint: INIT = 'I', 'S' or 'R'.

6: TRIG(2*N) -- DOUBLE PRECISION array Input/Output
On entry: if INIT = 'S' or 'R', TRIG must contain the required coefficients calculated in a previous call of the routine. Otherwise TRIG need not be set. On exit: TRIG contains the required coefficients (computed by the routine if INIT = 'I').

7: WORK(2*M*N) -- DOUBLE PRECISION array Workspace

8: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1
On entry M < 1.

IFAIL= 2
On entry N < 1.

IFAIL= 3
On entry INIT is not one of 'I', 'S' or 'R'.

IFAIL= 4
On entry INIT = 'S', but none of C06FPF, C06FQF and C06FRF has previously been called.
CHAPTER 22. NAG LIBRARY ROUTINES

IFAIL= 5
On entry INIT = 'S' or 'R', but the array TRIG and the current value of n are inconsistent.

7. Accuracy

Some indication of accuracy can be obtained by performing a subsequent inverse transform and comparing the results with the original sequence (in exact arithmetic they would be identical).

8. Further Comments

The time taken by the routine is approximately proportional to \(nm\log n\), but also depends on the factors of \(n\). The routine is fastest if the only prime factors of \(n\) are 2, 3 and 5, and is particularly slow if \(n\) is a large prime, or has large prime factors.

——

Discrete Fourier transform of bivariate complex data

— nagc.ht —
1. Purpose

C06FUF computes the two-dimensional discrete Fourier transform of a bivariate sequence of complex data values. This routine is designed to be particularly efficient on vector processors.

2. Specification

```fortran
SUBROUTINE C06FUF (M, N, X, Y, INIT, TRIGM, TRIGN, WORK, IFAIL)
INTEGER M, N, IFAIL
DOUBLE PRECISION X(M*N), Y(M*N), TRIGM(2*M), TRIGN(2*N), WORK(2*M*N)
CHARACTER*1 INIT
```

3. Description

This routine computes the two-dimensional discrete Fourier transform of a bivariate sequence of complex data values \( z_{j_1 j_2} \)

where \( j_1 = 0,1,\ldots,m-1 \), \( j_2 = 0,1,\ldots,n-1 \).

The discrete Fourier transform is here defined by:

\[
\begin{align*}
\hat{z}_{k_1 k_2} &= \frac{1}{\sqrt{mn}} \sum_{j_1=0}^{m-1} \sum_{j_2=0}^{n-1} z_{j_1 j_2} \exp(-2\pi i \left( \frac{j_1 k_1}{m} + \frac{j_2 k_2}{n} \right)), \\
&= \frac{1}{\sqrt{mn}} \sum_{j_1=0}^{m-1} \sum_{j_2=0}^{n-1} z_{j_1 j_2} \exp(-2\pi i \left( \frac{j_1 1}{m} + \frac{j_2 2}{n} \right)),
\end{align*}
\]

where \( k_1 = 0,1,\ldots,m-1 \), \( k_2 = 0,1,\ldots,n-1 \).

(Note the scale factor of \( \frac{1}{\sqrt{mn}} \) in this definition.)
To compute the inverse discrete Fourier transform, defined with exp(+2(pi)i(...)) in the above formula instead of exp(-2(pi)i(...)), this routine should be preceded and followed by calls of C06GCF to form the complex conjugates of the data values and the transform.

This routine calls C06FRF to perform multiple one-dimensional discrete Fourier transforms by the fast Fourier transform (FFT) algorithm in Brigham [1]. It is designed to be particularly efficient on vector processors.

4. References

5. Parameters

1: M -- INTEGER Input
   On entry: the number of rows, m, of the arrays X and Y.
   Constraint: M >= 1.

2: N -- INTEGER Input
   On entry: the number of columns, n, of the arrays X and Y.
   Constraint: N >= 1.

3: X(M,N) -- DOUBLE PRECISION array Input/Output
   On entry: the real and imaginary parts of the complex data values must be stored in arrays X and Y respectively. If X and Y are regarded as two-dimensional arrays of dimension (0:M-1,0:N-1), then X(j,1:j) and Y(j,1:j) must contain the real and imaginary parts of z_{j}. On exit: the real and imaginary parts respectively of the corresponding elements of the computed transform.

4: Y(M,N) -- DOUBLE PRECISION array Input/Output
   On entry: the real and imaginary parts of the complex data values must be stored in arrays X and Y respectively. If X and Y are regarded as two-dimensional arrays of dimension (0:M-1,0:N-1), then X(j,1:j) and Y(j,1:j) must contain the real and imaginary parts of z_{j}. On exit: the real and imaginary parts respectively of the corresponding elements of the computed transform.

5: INIT -- CHARACTER*1 Input
   On entry: if the trigonometric coefficients required to compute the transforms are to be calculated by the routine and stored in the arrays TRIGM and TRIGN, then INIT must be
set equal to 'I', (Initial call).

If INIT contains 'S', (Subsequent call), then the routine assumes that trigonometric coefficients for the specified values of m and n are supplied in the arrays TRIGM and TRIGN, having been calculated in a previous call to the routine.

If INIT contains 'R', (Restart), then the routine assumes that trigonometric coefficients for the particular values of m and n are supplied in the arrays TRIGM and TRIGN, but does not check that the routine has previously been called. This option allows the TRIGM and TRIGN arrays to be stored in an external file, read in and re-used without the need for a call with INIT equal to 'I'. The routine carries out a simple test to check that the current values of m and n are compatible with the arrays TRIGM and TRIGN. Constraint: INIT = 'I', 'S' or 'R'.

6: TRIGM(2*M) -- DOUBLE PRECISION array Input/Output
7: TRIGN(2*N) -- DOUBLE PRECISION array Input/Output

On entry: if INIT = 'S' or 'R', TRIGM and TRIGN must contain the required coefficients calculated in a previous call of the routine. Otherwise TRIGM and TRIGN need not be set.

If m=n the same array may be supplied for TRIGM and TRIGN.

On exit: TRIGM and TRIGN contain the required coefficients (computed by the routine if INIT = 'I').

8: WORK(2*M*N) -- DOUBLE PRECISION array Workspace
9: IFAIL -- INTEGER Input/Output

On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1
On entry M < 1.
IFAIL= 2
On entry N < 1.

IFAIL= 3
On entry INIT is not one of 'I', 'S' or 'R'.

IFAIL= 4
On entry INIT = 'S', but C06FUF has not previously been called.

IFAIL= 5
On entry INIT = 'S' or 'R', but at least one of the arrays TRIGM and TRIGN is inconsistent with the current value of M or N.

7. Accuracy

Some indication of accuracy can be obtained by performing a subsequent inverse transform and comparing the results with the original sequence (in exact arithmetic they would be identical).

8. Further Comments

The time taken by the routine is approximately proportional to mn*\log(mn), but also depends on the factorization of the individual dimensions m and n. The routine is somewhat faster than average if their only prime factors are 2, 3 or 5; and fastest of all if they are powers of 2.

9. Example

This program reads in a bivariate sequence of complex data values and prints the two-dimensional Fourier transform. It then performs an inverse transform and prints the sequence so obtained, which may be compared to the original data values.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

C06GBF(3NAG) Foundation Library (12/10/92) C06GBF(3NAG)

C06 -- Summation of Series C06GBF
C06GBF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose
C06GBF forms the complex conjugate of a Hermitian sequence of n data values.

2. Specification

SUBROUTINE C06GBF (X, N, IFAIL)
INTEGER N, IFAIL
DOUBLE PRECISION X(N)

3. Description
This is a utility routine for use in conjunction with C06EAF, C06EBF, C06FAF(∗) or C06FBF(*) to calculate inverse discrete Fourier transforms (see the Chapter Introduction).

4. References
None.

5. Parameters

1: X(N) -- DOUBLE PRECISION array Input/Output
On entry: if the data values z are written as x +iy and
j j j
if X is declared with bounds (0:N-1) in the (sub)program
from which C06GBF is called, then for 0\leq j\leq n/2, X(j) must
contain x (\textasciitilde x )\), while for n/2 < j \leq n-1, X(j) must contain
j n-j
-y (\textasciitilde y ). In other words, X must contain the Hermitian
j n-j
sequence in Hermitian form. (See also Section 2.1.2 of the
Chapter Introduction). On exit: the imaginary parts y are
j
negated. The real parts x are not referenced.

2: N -- INTEGER Input
On entry: the number of data values, n. Constraint: N \geq 1.

3: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not
familiar with this parameter (described in the Essential
Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see
Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
N < 1.

7. Accuracy

Exact.

8. Further Comments

The time taken by the routine is negligible.

9. Example

This program reads in a sequence of real data values, calls
C06EAF followed by C06GBF to compute their inverse discrete
Fourier transform, and prints this after expanding it from
Hermitian form into a full complex sequence.

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.
Complex conjugate of a sequence of n data values

C06GCF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

C06GCF forms the complex conjugate of a sequence of n data values.

2. Specification

\begin{verbatim}
SUBROUTINE C06GCF (Y, N, IFAIL)
INTEGER N, IFAIL
DOUBLE PRECISION Y(N)
\end{verbatim}

3. Description

This is a utility routine for use in conjunction with C06ECF or C06FCF(*) to calculate inverse discrete Fourier transforms (see the Chapter Introduction).

4. References

None.
\end{verbatim}
5. Parameters

1: Y(N) -- DOUBLE PRECISION array Input/Output
   On entry: if Y is declared with bounds (0:N-1) in the (sub) program which C06GCF is called, then Y(j) must contain the imaginary part of the jth data value, for 0\leq j\leq n-1. On exit: these values are negated.

2: N -- INTEGER Input
   On entry: the number of data values, n. Constraint: N \geq 1.

3: IFAIL -- INTEGER Input/Output
   On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
   On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
   N < 1.

7. Accuracy

Exact.

8. Further Comments

The time taken by the routine is negligible.

9. Example

This program reads in a sequence of complex data values and prints their inverse discrete Fourier transform as computed by calling C06GCF, followed by C06ECF and C06GCF again.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
Complex conjugates of m Hermitian sequences

C06 -- Summation of Series
C06GQF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

C06GQF forms the complex conjugates of m Hermitian sequences, each containing n data values.

2. Specification

SUBROUTINE C06GQF (M, N, X, IFAIL)
INTEGER M, N, IFAIL
DOUBLE PRECISION X(M*N)

3. Description

This is a utility routine for use in conjunction with C06FPF and C06FQF to calculate inverse discrete Fourier transforms (see the Chapter Introduction).

4. References

None.

5. Parameters

1:  M -- INTEGER  \hspace{1cm} \text{Input}
On entry: the number of Hermitian sequences to be conjugated, m. Constraint: M >= 1.
2: N -- INTEGER
   Input
   On entry: the number of data values in each Hermitian sequence, n. Constraint: N >= 1.

3: X(M,N) -- DOUBLE PRECISION array
   Input/Output
   On entry: the data must be stored in array X as if in a two-dimensional array of dimension (1:M,0:N-1); each of the m sequences is stored in a row of the array in Hermitian form. If the n data values z are written as x +iy, then for 0<=j<=n/2, x is contained in X(p,j), and for 1<=j<=(n-j)/2, y is contained in X(p,n-j). (See also Section 2.1.2 of the Chapter Introduction.) On exit: the imaginary parts y are negated. The real parts x are not referenced.

4: IFAIL -- INTEGER
   Input/Output
   On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
   On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1
   On entry M < 1.

IFAIL= 2
   On entry N < 1.

7. Accuracy

Exact.

8. Further Comments

None.
9. Example

This program reads in sequences of real data values which are assumed to be Hermitian sequences of complex data stored in Hermitian form. The sequences are expanded into full complex form using C06GSF and printed. The sequences are then conjugated (using C06GQF) and the conjugated sequences are expanded into complex form using C06GSF and printed out.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
2. Specification

```fortran
SUBROUTINE C06GSF (M, N, X, U, V, IFAIL)
INTEGER M, N, IFAIL
DOUBLE PRECISION X(M*N), U(M*N), V(M*N)
```

3. Description

This is a utility routine for use in conjunction with C06FPF and C06FQF (see the Chapter Introduction).

4. References

None.

5. Parameters

1: M -- INTEGER Input
   On entry: the number of Hermitian sequences, m, to be converted into complex form. Constraint: M >= 1.

2: N -- INTEGER Input
   On entry: the number of data values, n, in each sequence. Constraint: N >= 1.

3: X(M,N) -- DOUBLE PRECISION array Input
   On entry: the data must be stored in X as if in a two-dimensional array of dimension (1:M,0:N-1); each of the m sequences is stored in a row of the array in Hermitian form. If the n data values \( z \) are written as \( x + iy \), then for \( 0 \leq j \leq \frac{n}{2} \), \( x \) is contained in \( X(p,j) \), and for \( 1 \leq j \leq \frac{n-1}{2} \), \( y \) is contained in \( X(p,n-j) \). (See also Section 2.1.2 of the Chapter Introduction.)

4: U(M,N) -- DOUBLE PRECISION array Output

5: V(M,N) -- DOUBLE PRECISION array Output
   On exit: the real and imaginary parts of the \( m \) sequences of length \( n \), are stored in \( U \) and \( V \) respectively, as if in two-dimensional arrays of dimension (1:M,0:N-1); each of the \( m \) sequences is stored as if in a row of each array. In other words, if the real parts of the \( p \)th sequence are denoted by
x, for \(j=0,1,\ldots,n-1\) then the \(mn\) elements of the array \(U_j\) contain the values:

\[x_0, x_0, \ldots, x_0, x_1, x_1, \ldots, x_1, \ldots, x_n-1, x_n-1, \ldots, x_n-1\]

6: IFAIL -- INTEGER  
Input/Output

On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1
On entry \(M < 1\).

IFAIL= 2
On entry \(N < 1\).

7. Accuracy

Exact.

8. Further Comments

None.

9. Example

This program reads in sequences of real data values which are assumed to be Hermitian sequences of complex data stored in Hermitian form. The sequences are then expanded into full complex form using C06GSF and printed.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
22.3 nagd.ht

Quadrature

This chapter provides routines for the numerical evaluation of definite integrals in one or more dimensions and for evaluating weights and abscissae of integration rules.

The routines in this chapter are designed to estimate:

(a) the value of a one-dimensional definite integral of the form:

\[
\int_{a}^{b} f(x) \, dx \tag{1}
\]

where \( f(x) \) is defined by the user, either at a set of points \( (x_i, f(x_i)) \), for \( i=1,2,\ldots,n \) where \( a=x_1 < x_2 < \ldots < x_n = b \), or in the form of a function; and the limits of integration \( a, b \) may be finite or infinite.
Some methods are specially designed for integrands of the form
\[ f(x) = w(x)g(x) \]  
which contain a factor \( w(x) \), called the weight-function, of a specific form. These methods take full account of any peculiar behaviour attributable to the \( w(x) \) factor.

(b) the value of a multi-dimensional definite integral of the form:
\[ \int_{R} f(x, x, ..., x) dx ... dx dx \]  
where \( f(x, x, ..., x) \) is a function defined by the user and \( R \) is some region of \( n \)-dimensional space.

The simplest form of \( R \) is the \( n \)-rectangle defined by:
\[ a_i \leq x_i \leq b_i, \quad i=1,2,...,n \]  
where \( a_i \) and \( b_i \) are constants. When \( a_i \) and \( b_i \) are functions of \( x_j \) \((j<i)\), the region can easily be transformed to the rectangular form (see Davis and Rabinowitz [1] page 266). Some of the methods described incorporate the transformation procedure.

2.1. One-dimensional Integrals

To estimate the value of a one-dimensional integral, a quadrature rule uses an approximation in the form of a weighted sum of integrand values, i.e.,
\[ \int_{a}^{b} f(x)dx \approx \sum_{i=1}^{N} w_i f(x_i) \]  
The points \( x \) within the interval \([a,b]\) are known as the \( i \) abscissae, and the \( w \) are known as the weights.

More generally, if the integrand has the form (2), the corresponding formula is
\[ \int_{a}^{b} w(x)g(x) \, dx = \sum_{i=1}^{N} w_i g(x_i) \quad (6) \]

If the integrand is known only at a fixed set of points, these points must be used as the abscissae, and the weighted sum is calculated using finite-difference methods. However, if the functional form of the integrand is known, so that its value at any abscissa is easily obtained, then a wide variety of quadrature rules are available, each characterised by its choice of abscissae and the corresponding weights.

The appropriate rule to use will depend on the interval \([a,b]\) - whether finite or otherwise - and on the form of any \(w(x)\) factor in the integrand. A suitable value of \(N\) depends on the general behaviour of \(f(x)\); or of \(g(x)\), if there is a \(w(x)\) factor present.

Among possible rules, we mention particularly the Gaussian formulae, which employ a distribution of abscissae which is optimal for \(f(x)\) or \(g(x)\) of polynomial form.

The choice of basic rules constitutes one of the principles on which methods for one-dimensional integrals may be classified. The other major basis of classification is the implementation strategy, of which some types are now presented.

(a) Single rule evaluation procedures

A fixed number of abscissae, \(N\), is used. This number and the particular rule chosen uniquely determine the weights and abscissae. No estimate is made of the accuracy of the result.

(b) Automatic procedures

The number of abscissae, \(N\), within \([a,b]\) is gradually increased until consistency is achieved to within a level of accuracy (absolute or relative) requested by the user. There are essentially two ways of doing this; hybrid forms of these two methods are also possible:

(i) whole interval procedures (non-adaptive)

A series of rules using increasing values of \(N\) are successively applied over the whole interval \([a,b]\). It is clearly more economical if abscissae already used for a lower value of \(N\) can be used again as part of a higher-order formula. This principle is known as
optimal extension. There is no overlap between the abscissae used in Gaussian formulae of different orders. However, the Kronrod formulae are designed to give an optimal \((2N+1)\)-point formula by adding \((N+1)\) points to an \(N\)-point Gauss formula. Further extensions have been developed by Patterson.

(ii) adaptive procedures

The interval \([a,b]\) is repeatedly divided into a number of sub-intervals, and integration rules are applied separately to each sub-interval. Typically, the subdivision process will be carried further in the neighbourhood of a sharp peak in the integrand, than where the curve is smooth. Thus, the distribution of abscissae is adapted to the shape of the integrand.

Subdivision raises the problem of what constitutes an acceptable accuracy in each sub-interval. The usual global acceptability criterion demands that the sum of the absolute values of the error estimates in the sub-intervals should meet the conditions required of the error over the whole interval. Automatic extrapolation over several levels of subdivision may eliminate the effects of some types of singularities.

An ideal general-purpose method would be an automatic method which could be used for a wide variety of integrands, was efficient (i.e., required the use of as few abscissae as possible), and was reliable (i.e., always gave results within the requested accuracy). Complete reliability is unobtainable, and generally higher reliability is obtained at the expense of efficiency, and vice versa. It must therefore be emphasised that the automatic routines in this chapter cannot be assumed to be 100\% reliable. In general, however, the reliability is very high.

2.2. Multi-dimensional Integrals

A distinction must be made between cases of moderately low dimensionality (say, up to 4 or 5 dimensions), and those of higher dimensionality. Where the number of dimensions is limited, a one-dimensional method may be applied to each dimension, according to some suitable strategy, and high accuracy may be obtainable (using product rules). However, the number of integrand evaluations rises very rapidly with the number of dimensions, so that the accuracy obtainable with an acceptable amount of computational labour is limited; for example a product of 3-point rules in 20 dimensions would require more than 10.
integrand evaluations. Special techniques such as the Monte Carlo methods can be used to deal with high dimensions.

(a) Products of one-dimensional rules

Using a two-dimensional integral as an example, we have

$$\int_a^b \int_a^b f(x,y) \, dy \, dx = \sum_{i=1}^{N} w_i f(x_i, y_i)$$

(7)

where \((w_i, x_i)\) and \((v_j, y_j)\) are the weights and abscissae of the rules used in the respective dimensions.

A different one-dimensional rule may be used for each dimension, as appropriate to the range and any weight function present, and a different strategy may be used, as appropriate to the integrand behaviour as a function of each independent variable.

For a rule-evaluation strategy in all dimensions, the formula (8) is applied in a straightforward manner. For automatic strategies (i.e., attempting to attain a requested accuracy), there is a problem in deciding what accuracy must be requested in the inner integral(s). Reference to formula (7) shows that the presence of a limited but random error in the \(y\)-integration for different values of \(x\) can produce a 'jagged' function of \(x\), which may be difficult to integrate to the desired accuracy and for this reason products of automatic one-dimensional routines should be used with caution (see also Lyness [3]).

(b) Monte Carlo methods

These are based on estimating the mean value of the integrand sampled at points chosen from an appropriate statistical distribution function. Usually a variance reducing procedure is incorporated to combat the
22.3. NAGD.HT

fundamentally slow rate of convergence of the rudimentary form of the technique. These methods can be effective by comparison with alternative methods when the integrand contains singularities or is erratic in some way, but they are of quite limited accuracy.

(c) Number theoretic methods

These are based on the work of Korobov and Conroy and operate by exploiting implicitly the properties of the Fourier expansion of the integrand. Special rules, constructed from so-called optimal coefficients, give a particularly uniform distribution of the points throughout n-dimensional space and from their number theoretic properties minimize the error on a prescribed class of integrals. The method can be combined with the Monte Carlo procedure.

(d) Sag-Szekeres method

By transformation this method seeks to induce properties into the integrand which make it accurately integrable by the trapezoidal rule. The transformation also allows effective control over the number of integrand evaluations.

(e) Automatic adaptive procedures

An automatic adaptive strategy in several dimensions normally involves division of the region into subregions, concentrating the divisions in those parts of the region where the integrand is worst behaved. It is difficult to arrange with any generality for variable limits in the inner integral(s). For this reason, some methods use a region where all the limits are constants; this is called a hyper-rectangle. Integrals over regions defined by variable or infinite limits may be handled by transformation to a hyper-rectangle. Integrals over regions so irregular that such a transformation is not feasible may be handled by surrounding the region by an appropriate hyper-rectangle and defining the integrand to be zero outside the desired region. Such a technique should always be followed by a Monte Carlo method for integration.

The method used locally in each subregion produced by the adaptive subdivision process is usually one of three types: Monte Carlo, number theoretic or deterministic. Deterministic methods are usually the most rapidly convergent but are often expensive to use for high dimensionality and not as robust as the other techniques.

3. Recommendations on Choice and Use of Routines

The following three sub-sections consider in turn routines for:

one-dimensional integrals over a finite interval, and over a semi-infinite or an infinite interval; and multi-dimensional integrals. Within each sub-section, routines are classified by the type of method, which ranges from simple rule evaluation to automatic adaptive algorithms. The recommendations apply particularly when the primary objective is simply to compute the value of one or more integrals, and in these cases the automatic adaptive routines are generally the most convenient and reliable, although also the most expensive in computing time.

Note however that in some circumstances it may be counter-productive to use an automatic routine. If the results of the quadrature are to be used in turn as input to a further computation (e.g. an 'outer' quadrature or an optimization problem), then this further computation may be adversely affected by the 'jagged performance profile' of an automatic routine; a simple rule-evaluation routine may provide much better overall performance. For further guidance, the article Lyness [3] is recommended.

3.1. One-dimensional Integrals over a Finite Interval
(a) Integrand defined as a set of points

If \( f(x) \) is defined numerically at four or more points, then the Gill-Miller finite difference method (D01GAF) should be used. The interval of integration is taken to coincide with the range of \( x \)-values of the points supplied. It is in the nature of this problem that any routine may be unreliable. In order to check results independently and so as to provide an alternative technique the user may fit the integrand by Chebyshev series using E02ADF and then use routines E02AJF and E02AKF to evaluate its integral (which need not be restricted to the range of the integration points, as is the case for D01GAF). A further alternative is to fit a cubic spline to the data using E02BAF and then to evaluate its integral using E02BDF.

(b) Integrand defined as a function

If the functional form of \( f(x) \) is known, then one of the following approaches should be taken. They are arranged in the order from most specific to most general, hence the first applicable procedure in the list will be the most efficient. However, if the user does not wish to make any assumptions about the integrand, the most reliable routine to use will be D01AJF, although this will in general be less efficient for simple integrals.

(i) Rule-evaluation routines

If \( f(x) \) is known to be sufficiently well-behaved (more precisely, can be closely approximated by a polynomial of moderate degree), a Gaussian routine with a suitable number of abscissae may be used.

D01BBF may be used if it is required to examine the weights and abscissae. In this case, the user should write the code for the evaluation of quadrature summation (6).

(ii) Automatic adaptive routines

Firstly, several routines are available for integrands of the form \( w(x)g(x) \) where \( g(x) \) is a 'smooth' function (i.e., has no singularities, sharp peaks or violent oscillations in the interval of integration) and \( w(x) \) is a weight function of one of the following forms:

\[
(\alpha) \quad (\beta) \quad k \quad l
\]

if \( w(x) = (b-x)(x-a)(\log(b-x))(\log(x-a)) \)
where \( k,l=0 \) or \( 1 \), \((\alpha),(\beta)>-1\): use D01APF;

if \( w(x)=1/(x-c) \): use D01AQF (this integral is called the Hilbert transform of \( g \));

if \( w(x)=\cos((\omega)x) \) or \( \sin((\omega)x) \): use D01ANF (this routine can also handle certain types of singularities in \( g(x) \)).

Secondly, there are some routines for general \( f(x) \). If \( f(x) \) is known to be free of singularities, though it may be oscillatory, D01AKF may be used.

The most powerful of the finite interval integration routine is D01AJF (which can cope with singularities of several types). It may be used if none of the more specific situations described above applies. D01AJF is very reliable, particularly where the integrand has singularities other than at an end-point, or has discontinuities or cusps, and is therefore recommended where the integrand is known to be badly-behaved, or where its nature is completely unknown.

Most of the routines in this chapter require the user to supply a function or subroutine to evaluate the integrand at a single point.

If \( f(x) \) has singularities of certain types, discontinuities or sharp peaks occurring at known points, the integral should be evaluated separately over each of the subranges or D01ALF may be used.

3.2. One-dimensional Integrals over a Semi-infinite or Infinite Interval

(a) Integrand defined as a set of points

If \( f(x) \) is defined numerically at four or more points, and the portion of the integral lying outside the range of the points supplied may be neglected, then the Gill-Miller finite difference method, D01GAF, should be used.

(b) Integrand defined as a function

(i) Rule evaluation routines

If \( f(x) \) behaves approximately like a polynomial in \( x \), apart from a weight function of the form

\[-(\beta)x e^{-(\beta)x} \quad (\beta)>0 \text{ (semi-infinite interval, lower limit finite);}\]
or $e^{-(\beta)x}$ (semi-infinite interval, upper limit finite);

2

or $e^{-(\beta)(x-\alpha)}$ (infinite interval);

or if $f(x)$ behaves approximately like a $-1$ polynomial in $(x+B)$ (semi-infinite range);
then the Gaussian routines may be used.

D01BBF may be used if it is required to examine the weights and abscissae. In this case, the user should write the code for the evaluation of quadrature summation (6).

(ii) Automatic adaptive routines

D01AMF may be used, except for integrands which decay slowly towards an infinite end-point, and oscillate in sign over the entire range. For this class, it may be possible to calculate the integral by integrating between the zeros and invoking some extrapolation process.

D01ASF may be used for integrals involving weight functions of the form $\cos((\omega)x)$ and $\sin((\omega)x)$ over a semi-infinite interval (lower limit finite).

The following alternative procedures are mentioned for completeness, though their use will rarely be necessary:

(1) If the integrand decays rapidly towards an infinite end-point, a finite cut-off may be chosen, and the finite range methods applied.

(2) If the only irregularities occur in the finite part (apart from a singularity at the finite limit, with which D01AMF can cope), the range may be divided, with D01AMF used on the infinite part.

(3) A transformation to finite range may be employed, e.g.

$$1-t$$

$$x = \cdots \text{ or } x = -\log t$$

$$t \quad e$$
will transform \((0,\infty)\) to \((1,0)\) while for
infinite ranges we have
\[ +\infty \quad \infty \\
/ \quad / \\
\mid f(x)dx = \mid [f(x)+f(-x)]dx. \\
/ \quad / \\
-\infty \quad 0 \]
If the integrand behaves badly on \((-\infty,0)\)
and well on \((0,\infty)\) or vice versa it is
better to compute it as
\[ 0 \quad \infty \\
/ \quad / \\
\mid f(x)dx+ \mid f(x)dx. \\
/ \quad / \\
-\infty \quad 0 \]
This saves computing unnecessary function
values in the semi-infinite range where the
function is well behaved.

3.3. Multi-dimensional Integrals

A number of techniques are available in this area and the choice
depends to a large extent on the dimension and the required
accuracy. It can be advantageous to use more than one technique
as a confirmation of accuracy particularly for high dimensional
integrations. Many of the routines incorporate the transformation
procedure REGION which allows general product regions to be
easily dealt with in terms of conversion to the standard \(n\)-cube
region.

(a) Products of one-dimensional rules (suitable for up to about
5 dimensions)

If \(f(x_1,x_2,...,x_n)\) is known to be a sufficiently well-
behaved function of each variable \(x_i\), apart possibly from
weight functions of the types provided, a product of
Gaussian rules may be used. These are provided by D01BBF.
In this case, the user should write the code for the
evaluation of quadrature summation (6). Rules for finite,
semi-infinite and infinite ranges are included.

The one-dimensional routines may also be used recursively.
For example, the two-dimensional integral
\[ I= \mid \mid f(x,y)dydx \\
/ \quad / \\
1 \quad 2 \]

may be expressed as
\[ I = \int_{a}^{b} \frac{1}{\int_{a}^{b} F(x) \, dx}, \]
where
\[ F(x) = \int_{a}^{b} f(x, y) \, dy. \]

The user segment to evaluate \( F(x) \) will call the integration routine for the \( y \)-integration, which will call another user segment for \( f(x, y) \) as a function of \( y \) (\( x \) being effectively a constant). Note that, as Fortran is not a recursive language, a different library integration routine must be used for each dimension. Apart from this restriction, the full range of one-dimensional routines are available, for finite/infinite intervals, constant/variable limits, rule evaluation/automatic strategies etc.

(b) Automatic routines (D01GBF and D01FCF)

Both routines are for integrals of the form
\[ \int_{a}^{b} \int_{a}^{b} \int_{a}^{b} \cdots \int_{a}^{b} f(x_1, x_2, \ldots, x_n) \, dx_1 \, dx_2 \cdots dx_n. \]

D01GBF is an adaptive Monte Carlo routine. This routine is usually slow and not recommended for high accuracy work. It is a robust routine that can often be used for low accuracy results with highly irregular integrands or when \( n \) is large.

D01FCF is an adaptive deterministic routine. Convergence is fast for well-behaved integrands. Highly accurate results can often be obtained for \( n \) between 2 and 5, using significantly fewer integrand evaluations than would be required by D01GBF. The routine will usually work when the integrand is mildly singular.
and for \( n \leq 10 \) should be used before D01GBF. If it is known in advance that the integrand is highly irregular, it is best to compare results from at least two different routines.

There are many problems for which one or both of the routines will require large amounts of computing time to obtain even moderately accurate results. The amount of computing time is controlled by the number of integrand evaluations allowed by the user, and users should set this parameter carefully, with reference to the time available and the accuracy desired.

3.4. Decision Trees

(i) One-dimensional integrals over a finite interval. (If in doubt, follow the downward branch.)

Please see figure in printed Reference Manual

(ii) One-dimensional integrals over a semi-infinite or infinite interval. (If in doubt, follow the downward branch.)

Please see figure in printed Reference Manual

Approximation of the integral over a finite interval

--- nagd.ht ---

\begin{page}{manpageXXd01ajf}{NAG Documentation: d01ajf}\end{page}
Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

D01AJF is a general-purpose integrator which calculates an approximation to the integral of a function \( f(x) \) over a finite interval \([a,b]\):

\[
\int_{a}^{b} f(x) \, dx.
\]

2. Specification

```fortran
SUBROUTINE D01AJF (F, A, B, EPSABS, EPSREL, RESULT, 1
  ABSERR, W, LW, IW, LIW, IFAIL)
  INTEGER LW, IW(LIW), LIW, IFAIL
  DOUBLE PRECISION F, A, B, EPSABS, EPSREL, RESULT, ABSERR, W
  1 (LW)
  EXTERNAL F
```

3. Description

D01AJF is based upon the QUADPACK routine QAGS (Piessens et al [3]). It is an adaptive routine, using the Gauss 10-point and Kronrod 21-point rules. The algorithm, described by de Doncker [1], incorporates a global acceptance criterion (as defined by Malcolm and Simpson [2]) together with the (epsilon)-algorithm (Wynn [4]) to perform extrapolation. The local error estimation is described by Piessens et al [3].

The routine is suitable as a general purpose integrator, and can be used when the integrand has singularities, especially when these are of algebraic or logarithmic type.

D01AJF requires the user to supply a function to evaluate the integrand at a single point.

The routine D01ATF(*) uses an identical algorithm but requires the user to supply a subroutine to evaluate the integrand at an array of points. Therefore D01ATF(*) will be more efficient if the evaluation can be performed in vector mode on a vector-processing machine.

4. References

5. Parameters

1: F -- DOUBLE PRECISION FUNCTION, supplied by the user. External Procedure
   F must return the value of the integrand $f$ at a given point.

   Its specification is:

   \[
   \text{DOUBLE PRECISION FUNCTION F (X)}
   \]
   \[
   \begin{align*}
   1: & \quad X \quad \text{DOUBLE PRECISION} \quad \text{Input} \\
   & \quad \text{On entry: the point at which the integrand } f \text{ must be evaluated.} \\
   \end{align*}
   \]
   F must be declared as EXTERNAL in the (sub)program from which D01AJF is called. Parameters denoted as Input must not be changed by this procedure.

2: A -- DOUBLE PRECISION Input
   On entry: the lower limit of integration, $a$.

3: B -- DOUBLE PRECISION Input
   On entry: the upper limit of integration, $b$. It is not necessary that $a < b$.

4: EPSABS -- DOUBLE PRECISION Input
   On entry: the absolute accuracy required. If EPSABS is negative, the absolute value is used. See Section 7.

5: EPSREL -- DOUBLE PRECISION Input
   On entry: the relative accuracy required. If EPSREL is negative, the absolute value is used. See Section 7.

6: RESULT -- DOUBLE PRECISION Output
6. Error Indicators and Warnings

Errors or warnings specified by the routine:
If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1
The maximum number of subdivisions allowed with the given workspace has been reached without the accuracy requirements being achieved. Look at the integrand in order to determine the integration difficulties. If the position of a local difficulty within the interval can be determined (e.g. a singularity of the integrand or its derivative, a peak, a discontinuity, etc) you will probably gain from splitting up the interval at this point and calling the integrator on the subranges. If necessary, another integrator, which is designed for handling the type of difficulty involved, must be used. Alternatively, consider relaxing the accuracy requirements specified by EPSABS and EPSREL, or increasing the amount of workspace.

IFAIL= 2
Round-off error prevents the requested tolerance from being achieved. The error may be under-estimated. Consider requesting less accuracy.

IFAIL= 3
Extremely bad local integrand behaviour causes a very strong subdivision around one (or more) points of the interval.

IFAIL= 4
The requested tolerance cannot be achieved, because the extrapolation does not increase the accuracy satisfactorily; the returned result is the best which can be obtained. The same advice applies as in the case of IFAIL = 1.

IFAIL= 5
The integral is probably divergent, or slowly convergent. Please note that divergence can occur with any non-zero value of IFAIL.

IFAIL= 6
On entry LW < 4,
or LIW < 1.

7. Accuracy

The routine cannot guarantee, but in practice usually achieves, the following accuracy:

$$|I\text{-RESULT}| \leq tol,$$
where
\[
\text{tol} = \max\{\|\text{EPSABS}\|, |\text{EPSREL}||I|\},
\]
and EPSABS and EPSREL are user-specified absolute and relative error tolerance. Moreover it returns the quantity ABSERR which, in normal circumstances, satisfies
\[
|I-\text{RESULT}| \leq \text{ABSERR} \leq \text{tol}.
\]

8. Further Comments

The time taken by the routine depends on the integrand and the accuracy required.

If IFAIL /= 0 on exit, then the user may wish to examine the contents of the array W, which contains the end-points of the sub-intervals used by D01AJF along with the integral contributions and error estimates over the sub-intervals.

Specifically, for i=1,2,...,n, let \( r_i \) denote the approximation to the value of the integral over the sub-interval \([a_i, b_i]\) in the partition of \([a, b]\) and \( e_i \) be the corresponding absolute error estimate.

\[
\begin{align*}
\text{b} & \text{ n} \\
\text{/} & \text{ --} \\
\text{Then, } |f(x)dx| & \approx r_i \text{ and RESULT} > r_i \text{, unless D01AJF terminates} \\
\text{/ i} & \text{ -- i} \\
\text{a} & \text{i=1} \\
\text{i}
\end{align*}
\]

while testing for divergence of the integral (see Piessens et al [3], Section 3.4.3). In this case, RESULT (and ABSERR) are taken to be the values returned from the extrapolation process. The value of n is returned in IW(1), and the values a, b, e and r are stored consecutively in the array W, that is:

\[
\begin{align*}
\text{a} = & \text{W(i)}, \\
\text{b} = & \text{W(n+i)}, \\
\text{e} = & \text{W(2n+i)} \text{ and}
\end{align*}
\]
9. Example

To compute

\[
\int_{0}^{2\pi} \frac{x \sin(30x)}{1 - (x^2)} \ dx.
\]

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

---

Adaptive integration over a finite integral

--- nagd.ht ---

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.
1. Purpose

D01AKF is an adaptive integrator, especially suited to oscillating, non-singular integrands, which calculates an approximation to the integral of a function \( f(x) \) over a finite interval \([a, b]\):

\[
\int_a^b f(x) \, dx.
\]

2. Specification

```fortran
SUBROUTINE D01AKF (F, A, B, EPSABS, EPSREL, RESULT, 1
   ABSERR, W, LW, IW, LIW, IFAIL)

INTEGER LW, IW(LIW), LIW, IFAIL
DOUBLE PRECISION F, A, B, EPSABS, EPSREL, RESULT, ABSERR, W
               (LW)
EXTERNAL F
```

3. Description

D01AKF is based upon the QUADPACK routine QAG (Piessens et al [3]). It is an adaptive routine, using the Gauss 30-point and Kronrod 61-point rules. A 'global' acceptance criterion (as defined by Malcolm and Simpson [1]) is used. The local error estimation is described in Piessens et al [3].

Because this routine is based on integration rules of high order, it is especially suitable for non-singular oscillating integrands.

D01AKF requires the user to supply a function to evaluate the integrand at a single point.

The routine D01AUF(*) uses an identical algorithm but requires the user to supply a subroutine to evaluate the integrand at an array of points. Therefore D01AUF(*) will be more efficient if the evaluation can be performed in vector mode on a vector-processing machine.

D01AUF(*) also has an additional parameter KEY which allows the user to select from six different Gauss-Kronrod rules.

4. References

5. Parameters

1: F -- DOUBLE PRECISION FUNCTION, supplied by the user. 
   External Procedure
F must return the value of the integrand f at a given point.

   Its specification is:

   DOUBLE PRECISION FUNCTION F (X)
   DOUBLE PRECISION X

   1: X -- DOUBLE PRECISION Input
      On entry: the point at which the integrand f must be 
      evaluated.
      F must be declared as EXTERNAL in the (sub)program from 
      which D01AKF is called. Parameters denoted as Input 
      must not be changed by this procedure.

2: A -- DOUBLE PRECISION Input
   On entry: the lower limit of integration, a.

3: B -- DOUBLE PRECISION Input
   On entry: the upper limit of integration, b. It is not 
   necessary that a<b.

4: EPSABS -- DOUBLE PRECISION Input
   On entry: the absolute accuracy required. If EPSABS is 
   negative, the absolute value is used. See Section 7.

5: EPSREL -- DOUBLE PRECISION Input
   On entry: the relative accuracy required. If EPSREL is 
   negative, the absolute value is used. See Section 7.

6: RESULT -- DOUBLE PRECISION Output
   On exit: the approximation to the integral I.

7: ABSERR -- DOUBLE PRECISION Output
   On exit: an estimate of the modulus of the absolute error, 
   which should be an upper bound |I-RESULT|. 
CHAPTER 22. NAG LIBRARY ROUTINES

8: W(LW) -- DOUBLE PRECISION array  
   Output
   On exit: details of the computation, as described in 
   Section 8.

9: LW -- INTEGER  
   Input
   On entry: the dimension of W, as declared in the (sub) 
   program from which D01AKF is called. The value of LW 
   (together with that of LIW below) imposes a bound on the 
   number of sub-intervals into which the interval of 
   integration may be divided by the routine. The number of 
   sub-intervals cannot exceed LW/4. The more difficult the 
   integrand, the larger LW should be. Suggested value: a value 
   in the range 800 to 2000 is adequate for most problems. 
   Constraint: LW >= 4. See IW below.

10: IW(LIW) -- INTEGER array  
    Output
    On exit: IW(1) contains the actual number of sub-intervals 
    used. The rest of the array is used as workspace.

11: LIW -- INTEGER  
    Input
    On entry: 
    the dimension of the array IW as declared in the 
    (sub)program from which D01AKF is called. 
    The number of sub-intervals into which the interval of 
    integration may be divided cannot exceed LIW. Suggested 

12: IFAIL -- INTEGER  
    Input/Output
    On entry: IFAIL must be set to 0, -1 or 1. Users who are 
    unfamiliar with this parameter should refer to the Essential 
    Introduction for details.

    On exit: IFAIL = 0 unless the routine detects an error or 
    gives a warning (see Section 6).

    For this routine, because the values of output parameters 
    may be useful even if IFAIL /=0 on exit, users are 
    recommended to set IFAIL to -1 before entry. It is then 
    essential to test the value of IFAIL on exit.

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are 
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
The maximum number of subdivisions allowed with the given 
workspace has been reached without the accuracy requirements
being achieved. Look at the integrand in order to determine
the integration difficulties. Probably another integrator
which is designed for handling the type of difficulty
involved must be used. Alternatively, consider relaxing the
accuracy requirements specified by EPSABS and EPSREL, or
increasing the amount of workspace.

IFAIL= 2
Round-off error prevents the requested tolerance from being
achieved. Consider requesting less accuracy.

IFAIL= 3
Extremely bad local integrand behaviour causes a very strong
subdivision around one (or more) points of the interval.
The same advice applies as in the case of IFAIL = 1.

IFAIL= 4
On entry LW < 4,
or LIW < 1.

7. Accuracy

The routine cannot guarantee, but in practice usually achieves,
the following accuracy:

\[ |I-RESULT| \leq \text{tol}, \]

where

\[ \text{tol} = \max\{|\text{EPSABS}|, |\text{EPSREL}| \times |I|\}, \]

and EPSABS and EPSREL are user-specified absolute and relative
error tolerances. Moreover it returns the quantity ABSERR which,
in normal circumstances satisfies

\[ |I-RESULT| \leq \text{ABSERR} \leq \text{tol}. \]

8. Further Comments

The time taken by the routine depends on the integrand and the
accuracy required.

If IFAIL /= 0 on exit, then the user may wish to examine the
contents of the array W, which contains the end-points of the
sub-intervals used by D01AKF along with the integral
contributions and error estimates over these sub-intervals.

Specifically, for i=1,2,...,n, let \( r \) denote the approximation to
the value of the integral over the sub-interval \([a_i, b_i]\) in the partition of \([a, b]\) and \(e_i\) be the corresponding absolute error estimate. Then, \(\int_{a_i}^{b_i} f(x)\,dx = r_i\) and \(\text{RESULT} = > r_i\). The value of \(n\) is returned in \(\text{IW}(1)\), and the values \(a_i\), \(b_i\), \(e_i\) and \(r_i\) are stored consecutively in the array \(\text{W}\), that is:

\[
a_i = \text{W}(i), \\
b_i = \text{W}(n+i), \\
e_i = \text{W}(2n+i) \quad \text{and} \\
r_i = \text{W}(3n+i).
\]

9. Example

To compute

\[
\int_0^{2\pi} x \sin(30x) \cos x \,dx.
\]

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
Approximate integration with local singular points

— nagd.ht —

\begin{verbatim}
D01ALF(3NAG)

D01 -- Quadrature
D01ALF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

D01ALF is a general purpose integrator which calculates an approximation to the integral of a function \( f(x) \) over a finite interval \([a,b]\):

\[
\int_{a}^{b} f(x) \, dx
\]

where the integrand may have local singular behaviour at a finite number of points within the integration interval.

2. Specification

\begin{verbatim}
SUBROUTINE D01ALF (F, A, B, NPTS, POINTS, EPSABS, EPSREL, 1
   RESULT, ABSERR, W, LW, IW, LIW, IFAIL)
   INTEGER NPTS, LW, IW(LIW), LIW, IFAIL
   DOUBLE PRECISION F, A, B, POINTS(*), EPSABS, EPSREL, 1
   RESULT, ABSERR, W(LW)
   EXTERNAL F
\end{verbatim}

3. Description

D01ALF is based upon the QUADPACK routine QAGP (Piessens et al
It is very similar to D01AJF, but allows the user to supply difficult. It is an adaptive routine, using the Gauss 10-point and Kronrod 21-point rules. The algorithm described by de Doncker [1], incorporates a global acceptance criterion (as defined by Malcolm and Simpson [2]) together with the (epsilon)-algorithm (Wynn [4]) to perform extrapolation. The user-supplied 'break-points' always occur as the end-points of some sub-interval during the adaptive process. The local error estimation is described by Piessens et al [3].

4. References

5. Parameters

1: F -- DOUBLE PRECISION FUNCTION, supplied by the user.
   External Procedure
   F must return the value of the integrand f at a given point.
   Its specification is:

   DOUBLE PRECISION FUNCTION F (X)
   DOUBLE PRECISION X

   1: X -- DOUBLE PRECISION  Input
      On entry: the point at which the integrand f must be evaluated.
      F must be declared as EXTERNAL in the (sub)program from
      which D01ALF is called. Parameters denoted as Input
      must not be changed by this procedure.

   2: A -- DOUBLE PRECISION  Input
      On entry: the lower limit of integration, a.

   3: B -- DOUBLE PRECISION  Input
      On entry: the upper limit of integration, b. It is not
necessary that $a < b$.

4: NPTS -- INTEGER  
On entry: the number of user-supplied break-points within the integration interval. Constraint: $NPTS \geq 0$.

5: POINTS(NPTS) -- DOUBLE PRECISION array  
On entry: the user-specified break-points. Constraint: the break-points must all lie within the interval of integration (but may be supplied in any order).

6: EPSABS -- DOUBLE PRECISION  
On entry: the absolute accuracy required. If EPSABS is negative, the absolute value is used. See Section 7.

7: EPSREL -- DOUBLE PRECISION  
On entry: the relative accuracy required. If EPSREL is negative, the absolute value is used. See Section 7.

8: RESULT -- DOUBLE PRECISION  
On entry: the approximation to the integral $I$.

9: ABSERR -- DOUBLE PRECISION  
On exit: an estimate of the modulus of the absolute error, which should be an upper bound for $|I - \text{RESULT}|$.

10: W(LW) -- DOUBLE PRECISION array  
On exit: details of the computation, as described in Section 8.

11: LW -- INTEGER  
On entry: the dimension of the array $W$ as declared in the (sub)program from which D01ALF is called.

The value of $LW$ (together with that of LIW below) imposes a bound on the number of sub-intervals into which the interval of integration may be divided by the routine. The number of sub-intervals cannot exceed $\frac{(LW-2\times NPTS-4)}{4}$. The more difficult the integrand, the larger $LW$ should be. Suggested value: a value in the range 800 to 2000 is adequate for most problems. Constraint: $LW \geq 2\times NPTS + 8$.

12: IW(LIW) -- INTEGER array  
On exit: $IW(1)$ contains the actual number of sub-intervals used. The rest of the array is used as workspace.

13: LIW -- INTEGER  
On entry: the dimension of the array $IW$ as declared in the (sub)program from which D01ALF is called.
The number of sub-intervals into which the interval of integration may be divided cannot exceed \((LIW-NPTS-2)/2\). Suggested value: \(LIW = LW/2\). Constraint: \(LIW \geq NPTS + 4\).

14: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. Users who are unfamiliar with this parameter should refer to the Essential Introduction for details.

On exit: IFAIL = 0 unless the routine detects an error or gives a warning (see Section 6).

For this routine, because the values of output parameters may be useful even if IFAIL /=0 on exit, users are recommended to set IFAIL to -1 before entry. It is then essential to test the value of IFAIL on exit.

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1
The maximum number of subdivisions allowed with the given workspace has been reached, without the accuracy requirements being achieved. Look at the integrand in order to determine the integration difficulties. If the position of a local difficulty within the interval can be determined (e.g. a singularity of the integrand or its derivative, a peak, a discontinuity, etc) it should be supplied to the routine as an element of the vector POINTS. If necessary, another integrator should be used, which is designed for handling the type of difficulty involved. Alternatively, consider relaxing the accuracy requirements specified by EPSABS and EPSREL, or increasing the amount of workspace.

IFAIL= 2
Round-off error prevents the requested tolerance from being achieved. The error may be under-estimated. Consider requesting less accuracy.

IFAIL= 3
Extremely bad local integrand behaviour causes a very strong subdivision around one (or more) points of the interval. The same advice applies as in the case of IFAIL = 1.

IFAIL= 4
The requested tolerance cannot be achieved, because the
extrapolation does not increase the accuracy satisfactorily; the result returned is the best which can be obtained. The same advice applies as in the case IFAIL = 1.

IFAIL= 5
The integral is probably divergent, or slowly convergent. Please note that divergence can also occur with any other non-zero value of IFAIL.

IFAIL= 6
The input is invalid: break-points are specified outside the integration range, NPTS > LIMIT or NPTS < 0. RESULT and ABSERR are set to zero.

IFAIL= 7
On entry LW<2*NPTS+8,
or LIW<NPTS+4.

7. Accuracy
The routine cannot guarantee, but in practice usually achieves, the following accuracy:

\[ |I-RESULT| \leq \text{tol}, \]

where

\[ \text{tol} = \max\{|EPSABS|,|EPSREL|*|I|\}, \]

and EPSABS and EPSREL are user-specified absolute and relative error tolerances. Moreover it returns the quantity ABSERR which, in normal circumstances, satisfies

\[ |I-RESULT| \leq \text{ABSERR} \leq \text{tol}. \]

8. Further Comments
The time taken by the routine depends on the integrand and on the accuracy required.

If IFAIL /= 0 on exit, then the user may wish to examine the contents of the array W, which contains the end-points of the sub-intervals used by D01ALF along with the integral contributions and error estimates over these sub-intervals.

Specifically, for i=1,2,...,n, let \( r \) denote the approximation to the value of the integral over the sub-interval \([a_i,b_i]\) in the partition of \([a,b]\) and \( e \) be the corresponding absolute error
estimate. Then, $\int f(x)\,dx = r$ and RESULT $= r$ unless D01ALF terminates while testing for divergence of the integral (see Piessens et al [3] Section 3.4.3). In this case, RESULT (and ABSERR) are taken to be the values returned from the extrapolation process. The value of n is returned in IW(1), and the values $a$, $b$, $e$ and $r$ are stored consecutively in the array W, that is:

\[
\begin{align*}
a &= W(i), \\
b &= W(n+i), \\
e &= W(2n+i) \text{ and} \\
r &= W(3n+i).
\end{align*}
\]

9. Example

To compute

\[
\begin{align*}
1 \\
/ \\
\int_{0}^{1/7} \frac{1}{|x-1/7|} \,dx
\end{align*}
\]

A break-point is specified at $x=1/7$, at which point the integrand is infinite. (For definiteness the function FST returns the value 0.0 at this point.)

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
Approximate integration over a (semi-)infinite interval

D01AMF calculates an approximation to the integral of a function $f(x)$ over an infinite or semi-infinite interval $[a, b]$:

$$ I = \int_{a}^{b} f(x) \, dx $$

2. Specification

```fortran
SUBROUTINE D01AMF (F, BOUND, INF, EPSABS, EPSREL, RESULT, ABSERR, W, LW, IW, LIW, IFAIL)
INTEGER INF, LW, IW(LIW), LIW, IFAIL
DOUBLE PRECISION F, BOUND, EPSABS, EPSREL, RESULT, ABSERR, W(LW)
EXTERNAL F
```

3. Description

D01AMF is based on the QUADPACK routine QAGI (Piessens et al [3]) $[0,1]$ using one of the identities:
CHAPTER 22. NAG LIBRARY ROUTINES

\[
\int_{-\infty}^{1} f(x) dx = \int_{0}^{1} f(a - \frac{1-t}{2}) dt
\]

\[
\int_{1}^{\infty} f(x) dx = \int_{0}^{1} f(a + \frac{1-t}{2}) dt
\]

\[
\int_{-\infty}^{\infty} \left( \frac{1-t}{1+t} \right) f(x) dx = \int_{0}^{1} \left( f(x) + f(-x) \right) dx = \int_{0}^{1} \left[ f\left( \frac{1-t}{2} \right) + f\left( \frac{-1+t}{2} \right) \right] dt
\]

where \( a \) represents a finite integration limit. An adaptive procedure, based on the Gauss seven-point and Kronrod 15-point rules, is then employed on the transformed integral. The algorithm, described by de Doncker [1], incorporates a global acceptance criterion (as defined by Malcolm and Simpson [2]) together with the (epsilon)-algorithm (Wynn [4]) to perform extrapolation. The local error estimation is described by Piessens et al. [3].

4. References

5. Parameters

1: F -- DOUBLE PRECISION FUNCTION, supplied by the user.

External Procedure

On entry: the point at which the integrand \( f \) must be
evaluated.
Its specification is:

```plaintext
DOUBLE PRECISION FUNCTION F (X)
DOUBLE PRECISION X

1: X -- DOUBLE PRECISION  Input
   On entry: the point at which the integrand f must be
   evaluated.
F must be declared as EXTERNAL in the (sub)program from
which D01AMF is called. Parameters denoted as Input
must not be changed by this procedure.

2: BOUND -- DOUBLE PRECISION Input
   On entry: the finite limit of the integration range (if
   present). BOUND is not used if the interval is doubly
   infinite.

3: INF -- INTEGER Input
   On entry: indicates the kind of integration range:
     if INF =1, the range is [BOUND, +infty)
     if INF =-1, the range is (-infty, BOUND]
     if INF =+2, the range is (-infty, +infty).
   Constraint: INF =-1, 1 or 2.

4: EPSABS -- DOUBLE PRECISION Input
   On entry: the absolute accuracy required. If EPSABS is
   negative, the absolute value is used. See Section 7.

5: EPSREL -- DOUBLE PRECISION Input
   On entry: the relative accuracy required. If EPSREL is
   negative, the absolute value is used. See Section 7.

6: RESULT -- DOUBLE PRECISION Output
   On exit: the approximation to the integral I.

7: ABSERR -- DOUBLE PRECISION Output
   On exit: an estimate of the modulus of the absolute error,
   which should be an upper bound for |I-RESULT|.

8: W(LW) -- DOUBLE PRECISION array Output
   On exit: details of the computation, as described in
   Section 8.

9: LW -- INTEGER Input
   On entry:
   the dimension of the array W as declared in the (sub)program
```
from which D01AMF is called. The value of LW (together with that of LIW below) imposes a bound on the number of sub-intervals into which the interval of integration may be divided by the routine. The number of sub-intervals cannot exceed LW/4. The more difficult the integrand, the larger LW should be. Suggested value: a value in the range 800 to 2000 is adequate for most problems. Constraint: LW $\geq 4$.

10: IW(LIW) -- INTEGER array
Output
On exit: IW(1) contains the actual number of sub-intervals used. The rest of the array is used as workspace.

11: LIW -- INTEGER
Input
On entry:
the dimension of the array IW as declared in the
(sub)program from which D01AMF is called.
The number of sub-intervals into which the interval of integration may be divided cannot exceed LIW. Suggested value: LIW = LW/4. Constraint: LIW $\geq 1$.

12: IFAIL -- INTEGER
Input/Output
On entry: IFAIL must be set to 0, -1 or 1. Users who are unfamiliar with this parameter should refer to the Essential Introduction for details.
On exit: IFAIL = 0 unless the routine detects an error or gives a warning (see Section 6).

For this routine, because the values of output parameters may be useful even if IFAIL $\neq 0$ on exit, users are recommended to set IFAIL to -1 before entry. It is then essential to test the value of IFAIL on exit.

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1
The maximum number of subdivisions allowed with the given workspace has been reached without the requested accuracy requirements being achieved. Look at the integrand in order to determine the integration difficulties. If the position of a local difficulty within the interval can be determined (e.g. a singularity of the integrand or its derivative, a peak, a discontinuity, etc) you will probably gain from splitting up the interval at this point and calling D01AMF on the infinite subrange and an appropriate integrator on
the finite subrange. Alternatively, consider relaxing the accuracy requirements specified by EPSABS and EPSREL, or increasing the amount of workspace.

IFAIL= 2
Round-off error prevents the requested tolerance from being achieved. The error may be underestimated. Consider requesting less accuracy.

IFAIL= 3
Extremely bad local integrand behaviour causes a very strong subdivision around one (or more) points of the interval. The same advice applies as in the case of IFAIL = 1.

IFAIL= 4
The requested tolerance cannot be achieved, because the extrapolation does not increase the accuracy satisfactorily; the returned result is the best which can be obtained. The same advice applies as in the case of IFAIL = 1.

IFAIL= 5
The integral is probably divergent, or slowly convergent. It must be noted that divergence can also occur with any other non-zero value of IFAIL.

IFAIL= 6
On entry LW < 4,

or LIW < 1,

or INF /= -1, 1 or 2.
Please note that divergence can occur with any non-zero value of IFAIL.

7. Accuracy

The routine cannot guarantee, but in practice usually achieves, the following accuracy:

\[ |I-RESULT| \leq \text{tol}, \]

where

\[ \text{tol} = \max\{|\text{EPSABS}|, |\text{EPSREL}| \times |I|\}, \]

and EPSABS and EPSREL are user-specified absolute and relative error tolerances. Moreover it returns the quantity ABSERR, which, in normal circumstances, satisfies

\[ |I-RESULT| \leq \text{ABSERR} \leq \text{tol}. \]
8. Further Comments

The time taken by the routine depends on the integrand and the accuracy required.

If IFAIL /= 0 on exit, then the user may wish to examine the contents of the array W, which contains the end-points of the sub-intervals used by D01AMF along with the integral contributions and error estimates over these sub-intervals.

Specifically, for i=1,2,...,n, let r denote the approximation to the value of the integral over the sub-interval [a ,b ] in the partition of [a,b] and e be the corresponding absolute error estimate. Then, | f(x)dx~r and RESULT= > r unless D01AMF terminates while testing for divergence of the integral (see Piessens et al [3] Section 3.4.3). In this case, RESULT (and ABSERR) are taken to be the values returned from the extrapolation process. The value of n is returned in IW(1), and the values a , b , e and r are stored consecutively in the array W, that is:

\[ a = W(i), b = W(n+i), e = W(2n+i) \text{ and } r = W(3n+i). \]

Note: that this information applies to the integral transformed to (0,1) as described in Section 3, not to the original integral.

9. Example

To compute

\[ \int_{0}^{\infty} \frac{1}{(x+1)\sqrt{x}} \, dx. \]

The exact answer is (\pi).
The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

Approximate sine or cosine transform over finite interval

---

D01ANF calculates an approximation to the sine or the cosine transform of a function $g$ over $[a,b]$:

$$
\int_{a}^{b} |g(x)||\sin((\omega)x)||\,dx \quad \text{or} \quad \int_{a}^{b} |g(x)||\cos((\omega)x)||\,dx
$$

(for a user-specified value of $(\omega)$).

2. Specification
3. Description

D01ANF is based upon the QUADPACK routine QF0UR (Piessens et al [3]). It is an adaptive routine, designed to integrate a function of the form \( g(x)w(x) \), where \( w(x) \) is either \( \sin((\omega)x) \) or \( \cos((\omega)x) \). If a sub-interval has length

\[-1 \leq L = |b-a|/2 \]

then the integration over this sub-interval is performed by means of a modified Clenshaw-Curtis procedure (Piessens and Branders [2]) if \( L(\omega)>4 \) and \( L \leq 20 \). In this case a Chebyshev-series approximation of degree 24 is used to approximate \( g(x) \), while an error estimate is computed from this approximation together with that obtained using Chebyshev-series of degree 12. If the above conditions do not hold then Gauss 7-point and Kronrod 15-point rules are used. The algorithm, described in [3], incorporates a global acceptance criterion (as defined in Malcolm and Simpson [1]) together with the (epsilon)-algorithm Wynn [4] to perform extrapolation. The local error estimation is described in [3].

4. References

5. Parameters

1: G -- DOUBLE PRECISION FUNCTION, supplied by the user. 

External Procedure
G must return the value of the function g at a given point.

Its specification is:

```
DOUBLE PRECISION FUNCTION G (X)
    DOUBLE PRECISION X

1: X -- DOUBLE PRECISION Input
    On entry: the point at which the function g must be evaluated.
    G must be declared as EXTERNAL in the (sub)program from which D01ANF is called. Parameters denoted as Input must not be changed by this procedure.

2: A -- DOUBLE PRECISION Input
    On entry: the lower limit of integration, a.

3: B -- DOUBLE PRECISION Input
    On entry: the upper limit of integration, b. It is not necessary that a<b.

4: OMEGA -- DOUBLE PRECISION Input
    On entry: the parameter (omega) in the weight function of the transform.

5: KEY -- INTEGER Input
    On entry: indicates which integral is to be computed:
    if KEY = 1, w(x)=cos((omega)x);
    if KEY = 2, w(x)=sin((omega)x).
    Constraint: KEY = 1 or 2.

6: EPSABS -- DOUBLE PRECISION Input
    On entry: the absolute accuracy required. If EPSABS is negative, the absolute value is used. See Section 7.

7: EPSREL -- DOUBLE PRECISION Input
    On entry: the relative accuracy required. If EPSREL is negative, the absolute value is used. See Section 7.

8: RESULT -- DOUBLE PRECISION Output
    On exit: the approximation to the integral I.

9: ABSERR -- DOUBLE PRECISION Output
    On exit: an estimate of the modulus of the absolute error, which should be an upper bound for |I-RESULT|.

10: W(LW) -- DOUBLE PRECISION array Output
    On exit: details of the computation, as described in Section 8.
11: LW -- INTEGER Input
On entry:
the dimension of the array W as declared in the (sub)program
from which D01ANF is called.
The value of LW (together with that of LIW below) imposes a
bound on the number of sub-intervals into which the interval
of integration may be divided by the routine. The number of
sub-intervals cannot exceed LW/4. The more difficult the
integrand, the larger LW should be. Suggested value: a value
in the range 800 to 2000 is adequate for most problems.
Constraint: LW >= 4.

12: IW(LIW) -- INTEGER array Output
On exit: IW(1) contains the actual number of sub-intervals
used. The rest of the array is used as workspace.

13: LIW -- INTEGER Input
On entry:
the dimension of the array IW as declared in the
(sub)program from which D01ANF is called.
The number of sub-intervals into which the interval of
integration may be divided cannot exceed LIW/2. Suggested

14: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. Users who are
unfamiliar with this parameter should refer to the Essential
Introduction for details.

On exit: IFAIL = 0 unless the routine detects an error or
gives a warning (see Section 6).

For this routine, because the values of output parameters
may be useful even if IFAIL /=0 on exit, users are
recommended to set IFAIL to -1 before entry. It is then
essential to test the value of IFAIL on exit.

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
The maximum number of subdivisions allowed with the given
workspace has been reached without the accuracy requested
being achieved. Look at the integrand in order to determine
the integration difficulties. If the position of a local
difficulty within the interval can be determined (e.g. a singularity of the integrand or its derivative, a peak, a discontinuity, etc) you will probably gain from splitting up the interval at this point and calling the integrator on the subranges. If necessary, another integrator, which is designed for handling the type of difficulty involved, must be used. Alternatively consider relaxing the accuracy requirements specified by EPSABS and EPSREL, or increasing amount of workspace.

IFAIL= 2
Round-off error prevents the requested tolerance from being achieved. The error may be underestimated. Consider requesting less accuracy.

IFAIL= 3
Extremely bad local behaviour of g(x) causes a very strong subdivision around one (or more) points of the interval. The same advice applies as in the case of IFAIL = 1.

IFAIL= 4
The requested tolerance cannot be achieved because the extrapolation does not increase the accuracy satisfactorily; the returned result is the best which can be obtained. The same advice applies as in the case of IFAIL = 1.

IFAIL= 5
The integral is probably divergent, or slowly convergent. It must be noted that divergence can occur with any non-zero value of IFAIL.

IFAIL= 6
On entry KEY < 1,

or      KEY > 2.

IFAIL= 7
On entry LW < 4,

or      LIW < 2.

7. Accuracy
The routine cannot guarantee, but in practice usually achieves, the following accuracy:

|I-RESULT|<=tol,

where
tol = \max\{|\text{EPSABS}|,|\text{EPSREL}| \times |I|\},

and EPSABS and EPSREL are user-specified absolute and relative tolerances. Moreover it returns the quantity ABSERR, which, in normal circumstances, satisfies

|I - RESULT| &lt; ABSERR &lt;= tol.

8. Further Comments

The time taken by the routine depends on the integrand and on the accuracy required.

If IFAIL /= 0 on exit, then the user may wish to examine the contents of the array W, which contains the end-points of the sub-intervals used by D01ANF along with the integral contributions and error estimates over these sub-intervals.

Specifically, for i=1,2,...,n, let \( r \) denote the approximation to the value of the integral over the sub-interval \([a_i, b_i]\) in the partition of \([a,b]\) and \( e \) be the corresponding absolute error estimate. Then, \( \int_{a_i}^{b_i} g(x) w(x) dx = r \) and RESULT = \( r \) unless D01ANF terminates while testing for divergence of the integral (see Piessens et al [3] Section 3.4.3). In this case, RESULT (and ABSERR) are taken to be the values returned from the extrapolation process. The value of n is returned in IW(1), and the values \( a_i, b_i, e_i \) and \( r_i \) are stored consecutively in the array \( W \), that is:

\[
\begin{align*}
& a_i = W(i), \\
& b_i = W(n+i), \\
& e_i = W(2n+i) \quad \text{and} \\
& r_i = W(3n+i).
\end{align*}
\]
9. Example

To compute

\[
\frac{1}{\int \ln(x) \sin(10\pi x) \, dx}.
\]

0

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

Adaptive integration of weighted function over an interval

— nagd.ht —
finite interval $[a, b]$:

\[
\frac{b}{I= \int_{a}^{b} g(x)w(x)\,dx}
\]

where the weight function $w$ has end-point singularities of algebraico-logarithmic type.

2. Specification

```fortran
SUBROUTINE D01APF (G, A, B, ALFA, BETA, KEY, EPSABS, 1
  EPSREL, RESULT, ABSERR, W, LW, IW, LIW, 2
  IFAIL)
  INTEGER KEY, LW, IW(LIW), LIW, IFAIL
  DOUBLE PRECISION G, A, B, ALFA, BETA, EPSABS, EPSREL, 1
  RESULT, ABSERR, W(LW)
  EXTERNAL G
```

3. Description

D01APF is based upon the QUADPACK routine QAWSE (Piessens et al [3]) and integrates a function of the form $g(x)w(x)$, where the weight function $w(x)$ may have algebraico-logarithmic singularities at the end-points $a$ and/or $b$. The strategy is a modification of that in D01AKF. We start by bisecting the original interval and applying modified Clenshaw-Curtis integration of orders 12 and 24 to both halves. Clenshaw-Curtis integration is then used on all sub-intervals which have $a$ or $b$ as one of their end-points (Piessens et al [2]). On the other sub-intervals Gauss-Kronrod (7–15 point) integration is carried out.

A 'global' acceptance criterion (as defined by Malcolm and Simpson [1]) is used. The local error estimation control is described by Piessens et al [3].

4. References

5. Parameters

1:  \[ G \] -- DOUBLE PRECISION FUNCTION, supplied by the user.  
    External Procedure  
    \[ G \] must return the value of the function \[ g \] at a given point \[ X \].  
    Its specification is:

    \[
    \begin{align*}
    \text{DOUBLE PRECISION FUNCTION} & \quad G \ (X) \\
    \text{DOUBLE PRECISION} & \quad X
    \end{align*}
    \]

    1:  \[ X \] -- DOUBLE PRECISION  
        \[ \text{Input} \]  
        \[ \text{On entry: the point at which the function } g \text{ must be evaluated.} \]
    \[ G \] must be declared as \texttt{EXTERNAL} in the (sub)program from which \texttt{D01APF} is called. Parameters denoted as \texttt{Input} must not be changed by this procedure.

2:  \[ A \] -- DOUBLE PRECISION  
    \[ \text{Input} \]  
    \[ \text{On entry: the lower limit of integration, } a. \]

3:  \[ B \] -- DOUBLE PRECISION  
    \[ \text{Input} \]  
    \[ \text{On entry: the upper limit of integration, } b. \text{ Constraint: } B > A. \]

4:  \[ \text{ALFA} \] -- DOUBLE PRECISION  
    \[ \text{Input} \]  
    \[ \text{On entry: the parameter (alpha) in the weight function.} \]
    \[ \text{Constraint: } \texttt{ALFA} > -1. \]

5:  \[ \text{BETA} \] -- DOUBLE PRECISION  
    \[ \text{Input} \]  
    \[ \text{On entry: the parameter (beta) in the weight function.} \]
    \[ \text{Constraint: } \texttt{BETA} > -1. \]

6:  \[ \text{KEY} \] -- INTEGER  
    \[ \text{Input} \]  
    \[ \text{On entry: indicates which weight function is to be used:} \]
    \[ \begin{align*}
    \text{(alpha) (beta)} & \quad \text{if } \texttt{KEY} = 1, \quad w(x) = (x-a)^{\alpha} (b-x)^{\beta} \\
    \text{(alpha) (beta)} & \quad \text{if } \texttt{KEY} = 2, \quad w(x) = (x-a)^{\alpha} (b-x)^{\beta} \ln(x-a) \\
    \text{(alpha) (beta)} & \quad \text{if } \texttt{KEY} = 3, \quad w(x) = (x-a)^{\alpha} (b-x)^{\beta} \ln(b-x) \\
    \text{(alpha) (beta)} & \quad \text{if } \texttt{KEY} = 4, \quad w(x) = (x-a)^{\alpha} (b-x)^{\beta} \ln(x-a) \ln(b-x)
    \end{align*} \]
Constraint: KEY = 1, 2, 3 or 4

7: EPSABS -- DOUBLE PRECISION
   On entry: the absolute accuracy required. If EPSABS is negative, the absolute value is used. See Section 7.

8: EPSREL -- DOUBLE PRECISION
   On entry: the relative accuracy required. If EPSREL is negative, the absolute value is used. See Section 7.

9: RESULT -- DOUBLE PRECISION
   On exit: the approximation to the integral I.

10: ABSERR -- DOUBLE PRECISION
    On exit: an estimate of the modulus of the absolute error, which should be an upper bound for $|I - \text{RESULT}|$.

11: W(LW) -- DOUBLE PRECISION array
    On exit: details of the computation, as described in Section 8.

12: LW -- INTEGER
    On entry: the dimension of the array W as declared in the (sub)program from which D01APF is called. The value of LW (together with that of LIW below) imposes a bound on the number of sub-intervals into which the interval of integration may be divided by the routine. The number of sub-intervals cannot exceed $\frac{\text{LW}}{4}$. The more difficult the integrand, the larger LW should be. Suggested value: LW = 800 to 2000 is adequate for most problems. Constraint: LW $\geq$ 8.

13: IW(LIW) -- INTEGER array
    On exit: IW(1) contains the actual number of sub-intervals used. The rest of the array is used as workspace.

14: LIW -- INTEGER
    On entry: the dimension of the array IW as declared in the (sub)program from which D01APF is called. The number of sub-intervals into which the interval of integration may be divided cannot exceed LIW. Suggested value: LIW = LW/4. Constraint: LIW $\geq$ 2.

15: IFAIL -- INTEGER
    On entry: IFAIL must be set to 0, -1 or 1. Users who are unfamiliar with this parameter should refer to the Essential Introduction for details.
On exit: IFAIL = 0 unless the routine detects an error or gives a warning (see Section 6).

For this routine, because the values of output parameters may be useful even if IFAIL /=0 on exit, users are recommended to set IFAIL to -1 before entry. It is then essential to test the value of IFAIL on exit.

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1
The maximum number of subdivisions allowed with the given workspace has been reached without the accuracy requirements being achieved. Look at the integrand in order to determine the integration difficulties. If the position of a discontinuity or a singularity of algebraico-logarithmic type within the interval can be determined, the interval must be split up at this point and the integrator called on the subranges. If necessary, another integrator, which is designed for handling the difficulty involved, must be used. Alternatively consider relaxing the accuracy requirements specified by EPSABS and EPSREL, or increasing the amount of workspace.

IFAIL= 2
Round-off error prevents the requested tolerance from being achieved. Consider requesting less accuracy.

IFAIL= 3
Extremely bad local integrand behaviour causes a very strong subdivision around one (or more) points of the interval. The same advice applies as in the case of IFAIL = 1.

IFAIL= 4
On entry B <= A, or ALFA <= -1, or BETA <= -1, or KEY < 1, or KEY > 4.
CHAPTER 22. NAG LIBRARY ROUTINES

IFAIL= 5
On entry LW < 8,
or LIW < 2.

7. Accuracy

The routine cannot guarantee, but in practice usually achieves, the following accuracy:

\[ |I-\text{RESULT}| \leq \text{tol}, \]

where

\[ \text{tol} = \max\{|\text{EPSABS}|,|\text{EPSREL}||I|\}, \]

and EPSABS and EPSREL are user-specified absolute and relative error tolerances.

Moreover it returns the quantity ABSERR which, in normal circumstances, satisfies:

\[ |I-\text{RESULT}| \leq \text{ABSERR} \leq \text{tol}. \]

8. Further Comments

The time taken by the routine depends on the integrand and on the accuracy required.

If IFAIL /= 0 on exit, then the user may wish to examine the contents of the array W, which contains the end-points of the sub-intervals used by D01APF along with the integral contributions and error estimates over these sub-intervals.

Specifically, for \( i = 1, 2, \ldots, n \), let \( r \) denote the approximation to the value of the integral over the sub-interval \( [a_i, b_i] \) in the partition of \( [a, b] \) and \( e \) be the corresponding absolute error estimate. Then, \( \int_a^b f(x)w(x)dx = \sum_{i=1}^{n} r_i \) and \( \text{RESULT} = \sum_{i=1}^{n} r_i \). The value of \( n \) is returned in IW(1), and the values \( a_i, b_i, e_i, \text{ and } r_i \) are stored consecutively in the array W, that is:
22.3. NAGD.HT

---

Hilbert transform over finite interval

--- nagd.ht ---

\begin{verbatim}
\end{verbatim}
D01AQF calculates an approximation to the Hilbert transform of a function \( g(x) \) over \([a,b]\):

\[
\int_{a}^{b} \frac{g(x)}{x-c} \, dx
\]

for user-specified values of \( a, b \) and \( c \).

2. Specification

\[
\begin{align*}
\text{SUBROUTINE D01AQF} & \quad (G, A, B, C, EPSABS, EPSREL, RESULT, \\
& \quad \text{ABSERR, W, LW, LIW, IFAIL}) \\
\text{INTEGER} & \quad \text{LW, LIW(LIW), LIW, IFAIL} \\
\text{DOUBLE PRECISION} & \quad G, A, B, C, EPSABS, EPSREL, RESULT, \\
& \quad \text{ABSERR, W(LW)} \\
\text{EXTERNAL} & \quad G
\end{align*}
\]

3. Description

D01AQF is based upon the QUADPACK routine QAWC (Piessens et al [3]) and integrates a function of the form \( g(x)w(x) \), where the weight function

\[
w(x) = \frac{1}{x-c}
\]

is that of the Hilbert transform. (If \( a < c < b \) the integral has to be interpreted in the sense of a Cauchy principal value.) It is an adaptive routine which employs a 'global' acceptance criterion (as defined by Malcolm and Simpson [1]). Special care is taken to
ensure that \( c \) is never the end-point of a sub-interval (Piessens et al\[2\]). On each sub-interval \((c, c)\) modified Clenshaw-Curtis integration of orders 12 and 24 is performed if \( c - d \leq c \leq c + d \)
\[1 \quad 2\]
where \( d = (c - c) / 20 \). Otherwise the Gauss 7-point and Kronrod 15-1 point rules are used. The local error estimation is described by Piessens et al \[3\].

4. References

5. Parameters

1: \( G \) -- DOUBLE PRECISION FUNCTION, supplied by the user.

   External Procedure

   \( G \) must return the value of the function \( g \) at a given point.

   Its specification is:

   \[
   \text{DOUBLE PRECISION FUNCTION } G (X) \\
   \text{DOUBLE PRECISION } X
   \]

1: \( X \) -- DOUBLE PRECISION

   On entry: the point at which the function \( g \) must be evaluated.

   \( G \) must be declared as EXTERNAL in the (sub)program from which DOIAQF is called. Parameters denoted as Input must not be changed by this procedure.

2: \( A \) -- DOUBLE PRECISION

   On entry: the lower limit of integration, \( a \).

3: \( B \) -- DOUBLE PRECISION

   On entry: the upper limit of integration, \( b \). It is not necessary that \( a < b \).

4: \( C \) -- DOUBLE PRECISION
On entry: the parameter $c$ in the weight function.
Constraint: $C$ must not equal $A$ or $B$.

5: EPSABS -- DOUBLE PRECISION Input
On entry: the absolute accuracy required. If EPSABS is negative, the absolute value is used. See Section 7.

6: EPSREL -- DOUBLE PRECISION Input
On entry: the relative accuracy required. If EPSREL is negative, the absolute value is used. See Section 7.

7: RESULT -- DOUBLE PRECISION Output
On exit: the approximation to the integral $I$.

8: ABSERR -- DOUBLE PRECISION Output
On exit: an estimate of the modulus of the absolute error, which should be an upper bound for $|I - \text{RESULT}|$.

9: W(LW) -- DOUBLE PRECISION array Output
On exit: details of the computation, as described in Section 8.

10: LW -- INTEGER Input
On entry:
the dimension of the array W as declared in the (sub)program from which D01AQF is called.
The value of LW (together with that of LIW below) imposes a bound on the number of sub-intervals into which the interval of integration may be divided by the routine. The number of sub-intervals cannot exceed LW/4. The more difficult the integrand, the larger LW should be. Suggested value: LW = 800 to 2000 is adequate for most problems. Constraint: LW >= 4.

11: IW(LIW) -- INTEGER array Output
On exit: IW(1) contains the actual number of sub-intervals used. The rest of the array is used as workspace.

12: LIW -- INTEGER Input
On entry:
the dimension of the array IW as declared in the (sub)program from which D01AQF is called.
The number of sub-intervals into which the interval of integration may be divided cannot exceed LIW. Suggested value: LIW = LW/4. Constraint: LIW >= 1.

13: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. Users who are unfamiliar with this parameter should refer to the Essential Introduction for details.
22.3. NAGD.HT

On exit: IFAIL = 0 unless the routine detects an error or gives a warning (see Section 6).

For this routine, because the values of output parameters may be useful even if IFAIL =/= 0 on exit, users are recommended to set IFAIL to -1 before entry. It is then essential to test the value of IFAIL on exit.

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1
The maximum number of subdivisions allowed with the given workspace has been reached without the accuracy requirements being achieved. Look at the integrand in order to determine the integration difficulties. Another integrator which is designed for handling the type of difficulty involved, must be used. Alternatively consider relaxing the accuracy requirements specified by EPSABS and EPSREL, or increasing the workspace.

IFAIL= 2
Round-off error prevents the requested tolerance from being achieved. Consider requesting less accuracy.

IFAIL= 3
Extremely bad local behaviour of g(x) causes a very strong subdivision around one (or more) points of the interval. The same advice applies as in the case of IFAIL = 1.

IFAIL= 4
On entry C = A or C = B.

IFAIL= 5
On entry LW < 4,

or

LIW < 1.

7. Accuracy

The routine cannot guarantee, but in practice usually achieves, the following accuracy:

|I-RESULT|<=tol,
where
\[
\text{tol} = \max\{|\text{EPSABS}|, |\text{EPSREL}| \times |I|\},
\]
and \text{EPSABS} and \text{EPSREL} are user-specified absolute and relative error tolerances. Moreover it returns the quantity \text{ABSERR} which, in normal circumstances satisfies:
\[
|I - \text{RESULT}| \leq \text{ABSERR} \leq \text{tol}.
\]

8. Further Comments

The time taken by the routine depends on the integrand and on the accuracy required.

If IFAIL \neq 0 on exit, then the user may wish to examine the contents of the array \text{W}, which contains the end-points of the sub-intervals used by D01AQF along with the integral contributions and error estimates over these sub-intervals.

Specifically, for \(i=1,2,\ldots, n\), let \(r\) denote the approximation to the value of the integral over the sub-interval \([a_i, b_i]\) in the partition of \([a, b]\) and \(e\) be the corresponding absolute error estimate. Then, \(\int_{a_i}^{b_i} g(x)w(x)dx \approx r\) and \(\text{RESULT} > r\). The value of \(\int_{a}^{b} \sum_{i=1}^{n} g(x)w(x)dx\) is returned in \(\text{IW}(1)\), and the values \(a_i, b_i, e_i, r_i\) are stored consecutively in the array \(\text{W}\), that is:

\[
\begin{align*}
a_i &= \text{W}(i), \\
b_i &= \text{W}(n+i), \\
e_i &= \text{W}(2n+i) \\
r_i &= \text{W}(3n+i).
\end{align*}
\]

9. Example
To compute the Cauchy principal value of

\[
\int_{-1}^{1} \frac{1}{(x + 0.01)(x - 0.01)^2} \, dx
\]

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

---

Approximate Sine or Cosine over \([a, \infty]\)

— nagd.ht —

D01ASF(3NAG) Foundation Library (12/10/92) D01ASF(3NAG)

D01 -- Quadrature

D01ASF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

D01ASF calculates an approximation to the sine or the cosine transform of a function g over \([a, \infty)\):
CHAPTER 22. NAG LIBRARY ROUTINES

infty
/
I= | g(x)||,sin((omega)x)dx or I=
/
a
infty
/
| g(x)||,cos((omega)x)dx
/
a
(for a user-specified value of (omega)).

2. Specification

SUBROUTINE D01ASF (G, A, OMEGA, KEY, EPSABS, RESULT,
1 ABSERR, LIMLST, LST, ERLST, RSLST,
2 IERLST, W, LW, IW, LIW, IFAIL)
INTEGER KEY, LIMLST, LST, IERLST(LIMLST), LW, IW
1 (LIW), LIW, IFAIL
DOUBLE PRECISION G, A, OMEGA, EPSABS, RESULT, ABSERR, ERLST
1 (LIMLST), RSLST(LIMLST), W(LW)
EXTERNAL G

3. Description

D01ASF is based upon the QUADPACK routine QAWFE (Piessens et al [2]). It is an adaptive routine, designed to integrate a function of the form g(x)ω(x) over a semi-infinite interval, where ω(x) is either sin((omega)x) or cos((omega)x). Over successive intervals

\[ C = [a+(k-1)c,a+kc], \quad k=1,2,\ldots,LST \]

integration is performed by the same algorithm as is used by D01ANF. The intervals C are of constant length

\[ c = \max\{2\lceil (\omega) \rceil,2\lceil (\omega) \rceil \}, \quad (\omega) \neq 0 \]

where \( \lceil (\omega) \rceil \) represents the largest integer less than or equal to \( (\omega) \). Since c equals an odd number of half periods, the integral contributions over succeeding intervals will alternate in sign when the function g is positive and monotonically decreasing over \([a,\infty)\). The algorithm, described by [2], incorporates a global acceptance criterion (as defined by Malcolm and Simpson [1]) together with the (epsilon)-algorithm (Wynn [3]) to perform extrapolation. The local error estimation is described by Piessens et al [2].
If (omega)=0 and KEY = 1, the routine uses the same algorithm as D01AMF (with EPSREL = 0.0).

In contrast to the other routines in Chapter D01, D01ASF works only with a user-specified absolute error tolerance (EPSABS). Over the interval C it attempts to satisfy the absolute accuracy requirement

\[ \text{EPSA} = U \times \text{EPSABS} \]

where \( U = (1-p)p \), for \( k=1,2,\ldots \) and \( p=0.9 \).

However, when difficulties occur during the integration over the \( k \)th sub-interval \( C \) such that the error flag IERLST(\( k \)) is non-zero, the accuracy requirement over subsequent intervals is relaxed. See Piessens et al [2] for more details.

4. References

5. Parameters

1: G -- DOUBLE PRECISION FUNCTION, supplied by the user. 
   
   External Procedure G must return the value of the function g at a given point.

   Its specification is:

   \[
   \text{DOUBLE PRECISION FUNCTION G(X)}
   \]

   \[
   \text{DOUBLE PRECISION X}
   \]

   1: X -- DOUBLE PRECISION 
   Input 
   On entry: the point at which the function g must be evaluated.

   G must be declared as EXTERNAL in the (sub)program from
which D01ASF is called. Parameters denoted as Input must not be changed by this procedure.

2: A -- DOUBLE PRECISION
   On entry: the lower limit of integration, a.

3: OMEGA -- DOUBLE PRECISION
   On entry: the parameter (omega) in the weight function of the transform.

4: KEY -- INTEGER
   On entry: indicates which integral is to be computed:
   if KEY = 1, w(x)=\cos((\omega)x);
   if KEY = 2, w(x)=\sin((\omega)x).
   Constraint: KEY = 1 or 2.

5: EPSABS -- DOUBLE PRECISION
   On entry: the absolute accuracy requirement. If EPSABS is negative, the absolute value is used. See Section 7.

6: RESULT -- DOUBLE PRECISION
   On exit: the approximation to the integral I.

7: ABSERR -- DOUBLE PRECISION
   On exit: an estimate of the modulus of the absolute error, which should be an upper bound for |I-RESULT|.

8: LIMLST -- INTEGER
   On entry: an upper bound on the number of intervals \( C_k \) needed for the integration. Suggested value: LIMLST = 50 is adequate for most problems. Constraint: LIMLST >= 3.

9: LST -- INTEGER
   On exit: the number of intervals \( C_k \) actually used for the integration.

10: ERLST(LIMLST) -- DOUBLE PRECISION array
    On exit: ERLST(k) contains the error estimate corresponding to the integral contribution over the interval \( C_k \), for \( k=1,2,...,LST \).

11: RSLST(LIMLST) -- DOUBLE PRECISION array
    On exit: RSLST(k) contains the integral contribution over the interval \( C_k \) for \( k=1,2,...,LST \).
12: IERLST(LIMLST) -- INTEGER array
   Output
   On exit: IERLST(k) contains the error flag corresponding to
   RSLST(k), for k=1,2,...,LST. See Section 6.

13: W(LW) -- DOUBLE PRECISION array
   Workspace

14: LW -- INTEGER
   Input
   On entry:
   the dimension of the array W as declared in the (sub)program
   from which D01ASF is called.
   The value of LW (together with that of LIW below) imposes a
   bound on the number of sub-intervals into which each
   interval C may be divided by the routine. The number of
   sub-intervals cannot exceed LW/4. The more difficult the
   integrand, the larger LW should be. Suggested value: a value
   in the range 800 to 2000 is adequate for most problems.
   Constraint: LW >= 4.

15: IW(LIW) -- INTEGER array
   Output
   On exit: IW(1) contains the maximum number of sub-intervals
   actually used for integrating over any of the intervals C .
   The rest of the array is used as workspace.

16: LIW -- INTEGER
   Input
   On entry:
   the dimension of the array IW as declared in the
   (sub)program from which D01ASF is called.
   The number of sub-intervals into which each interval C may
   be divided cannot exceed LIW/2. Suggested value: LIW = LW/2.
   Constraint: LIW >= 2.

17: IFAIL -- INTEGER
   Input/Output
   On entry: IFAIL must be set to 0, -1 or 1. Users who are
   unfamiliar with this parameter should refer to the Essential
   Introduction for details.

   On exit: IFAIL = 0 unless the routine detects an error or
   gives a warning (see Section 6).

   For this routine, because the values of output parameters
   may be useful even if IFAIL /=0 on exit, users are
   recommended to set IFAIL to -1 before entry. It is then
   essential to test the value of IFAIL on exit.

6. Error Indicators and Warnings

Errors or warnings specified by the routine:
If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1
The maximum number of subdivisions allowed with the given workspace has been reached without the accuracy requirements being achieved. Look at the integrand in order to determine the integration difficulties. If the position of a local difficulty within the interval can be determined (e.g. a singularity of the integrand or its derivative, a peak, a discontinuity, etc) you will probably gain from splitting up the interval at this point and calling D01ASF on the infinite subrange and an appropriate integrator on the finite subrange. Alternatively, consider relaxing the accuracy requirements specified by EPSABS or increasing the amount of workspace.

IFAIL= 2
Round-off error prevents the requested tolerance from being achieved. The error may be underestimated. Consider requesting less accuracy.

IFAIL= 3
Extremely bad local integrand behaviour causes a very strong subdivision around one (or more) points of the interval. The same advice applies as in the case of IFAIL = 1.

IFAIL= 4
The requested tolerance cannot be achieved, because the extrapolation does not increase the accuracy satisfactorily; the returned result is the best which can be obtained. The same advice applies as in the case of IFAIL = 1.

IFAIL= 5
The integral is probably divergent, or slowly convergent. Please note that divergence can occur with any non-zero value of IFAIL.

IFAIL= 6
On entry KEY < 1,
or KEY > 2,
or LIMLST < 3.

IFAIL= 7
Bad integration behaviour occurs within one or more of the intervals C . Location and type of the difficulty involved
can be determined from the vector IERLST (see below).

IFAIL= 8
Maximum number of intervals \( C \) (\( = \text{LIMLST} \)) allowed has been
achieved. Increase the value of \text{LIMLST} to allow more cycles.

IFAIL= 9
The extrapolation table constructed for convergence
acceleration of the series formed by the integral
contribution over the intervals \( C \), does not converge to the
required accuracy.

IFAIL= 10
On entry LW < 4,
or LIW < 2.

In the cases IFAIL = 7, 8 or 9, additional information about the
cause of the error can be obtained from the array IERLST, as
follows:

IERLST\( (k) = 1 \)
The maximum number of subdivisions = \( \min(\text{LW}/4,\text{LIW}/2) \) has
been achieved on the \( k \)th interval.

IERLST\( (k) = 2 \)
Occurrence of round-off error is detected and prevents the
tolerance imposed on the \( k \)th interval from being achieved.

IERLST\( (k) = 3 \)
Extremely bad integrand behaviour occurs at some points of
the \( k \)th interval.

IERLST\( (k) = 4 \)
The integration procedure over the \( k \)th interval does not
converge (to within the required accuracy) due to round-off
in the extrapolation procedure invoked on this interval. It
is assumed that the result on this interval is the best
which can be obtained.

IERLST\( (k) = 5 \)
The integral over the \( k \)th interval is probably divergent or
slowly convergent. It must be noted that divergence can
occur with any other value of IERLST\( (k) \).

7. Accuracy
The routine cannot guarantee, but in practice usually achieves,
the following accuracy:

\[ |I\text{-RESULT}| \leq |\text{EPSABS}|, \]

where EPSABS is the user-specified absolute error tolerance. Moreover, it returns the quantity ABSERR, which, in normal circumstances, satisfies

\[ |I\text{-RESULT}| \leq |\text{ABSERR}| \leq |\text{EPSABS}|. \]

8. Further Comments

None.

9. Example

To compute

\[
\int_0^\infty \frac{\cos(\pi x/2)}{x} \, dx.
\]

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
22.3. NAGD-HT

D01 -- Quadrature

D01BBF

D01BBF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

Note for users via the Axiom system: the interface to this routine has been enhanced for use with Axiom and is slightly different to that offered in the standard version of the Foundation Library.

1. Purpose

D01BBF returns the weights and abscissae appropriate to a Gaussian quadrature formula with a specified number of abscissae. The formulae provided are Gauss-Legendre, Gauss-Rational, Gauss-Laguerre and Gauss-Hermite.

2. Specification

SUBROUTINE D01BBF (A, B, ITYPE, N, WEIGHT, ABSCIS, GTYPE, IFAIL)

INTEGER ITYPE, N, GTYPE, IFAIL

DOUBLE PRECISION A, B, WEIGHT(N), ABSCIS(N)

3. Description

This routine returns the weights and abscissae for use in the Gaussian quadrature of a function \( f(x) \). The quadrature takes the form

\[
S = \sum_{i=1}^{n} w_i f(x_i)
\]

where \( w_i \) are the weights and \( x_i \) are the abscissae (see Davis and Rabinowitz [1], Froberg [2], Ralston [3] or Stroud and Secrest [4]).

Weights and abscissae are available for Gauss-Legendre, Gauss-Rational, Gauss-Laguerre and Gauss-Hermite quadrature, and for a selection of values of \( n \) (see Section 5).

(a) Gauss-Legendre Quadrature:

\[
\int_{a}^{b} f(x) \, dx
\]
where $a$ and $b$ are finite and it will be exact for any function of the form
\[
\frac{2n-1}{\sum_{i=0}^{2n-1} c x^i}
\]

(b) Gauss-Rational quadrature:
\[
\int_{a}^{\infty} f(x) \, dx \quad (a+b>0) \quad \text{or} \quad \int_{-\infty}^{a} f(x) \, dx \quad (a+b<0)
\]
and will be exact for any function of the form
\[
\frac{2n-1}{\sum_{i=0}^{2n-1} c (x+b)^i}
\]

(c) Gauss-Laguerre quadrature, adjusted weights option:
\[
\int_{a}^{\infty} f(x) \, dx \quad (b>0) \quad \text{or} \quad \int_{-\infty}^{a} f(x) \, dx \quad (b<0)
\]
and will be exact for any function of the form
\[
\frac{-bx}{\sum_{i=0}^{2n-1} c x^i}
\]

(d) Gauss-Hermite quadrature, adjusted weights option:
\[
\int_{-\infty}^{\infty} f(x) \, dx
\]
and will be exact for any function of the form
22.3. NAGD.HT

\[ f(x) = \sum_{i=0}^{2n-1} c_i x^i \]

(e) Gauss-Laguerre quadrature, normal weights option:

\[
\int_{-\infty}^{\infty} e^{-bx} f(x) \, dx \quad \text{or} \quad \int_{a}^{\infty} e^{-bx} f(x) \, dx
\]

and will be exact for any function of the form

\[
\sum_{i=0}^{2n-1} c_i x^i
\]

(b<0)

(f) Gauss-Hermite quadrature, normal weights option:

\[
\int_{-\infty}^{\infty} e^{-bx(x-a)} f(x) \, dx
\]

and will be exact for any function of the form:

\[
\sum_{i=0}^{2n-1} c_i x^i
\]

Note: that the Gauss-Laguerre abscissae, with \(a=-1, b=+1\), are the zeros of the Legendre polynomials; the Gauss-Laguerre abscissae, with \(a=0, b=1\), are the zeros of the Laguerre polynomials; and the Gauss-Hermite abscissae, with \(a=0, b=1\), are the zeros of the Hermite polynomials.

4. References

5. Parameters

1: A -- DOUBLE PRECISION Input

2: B -- DOUBLE PRECISION Input
   On entry: the quantities a and b as described in the
   appropriate subsection of Section 3.

3: ITYPE -- INTEGER Input
   On entry: indicates the type of weights for Gauss-Laguerre
   or Gauss-Hermite quadrature (see Section 3):
   if ITYPE = 1, adjusted weights will be returned;
   if ITYPE = 0, normal weights will be returned.
   Constraint: ITYPE = 0 or 1.
   For Gauss-Legendre or Gauss-Rational quadrature, this
   parameter is not used.

4: N -- INTEGER Input
   On entry: the number of weights and abscissae to be
   returned, n. Constraint: N = 1,2,3,4,5,6,8,10,12,14,16,20,24,32,48 or 64.

5: WEIGHT(N) -- DOUBLE PRECISION array Output
   On exit: the N weights. For Gauss-Laguerre and Gauss-
   Hermite quadrature, these will be the adjusted weights if
   ITYPE = 1, and the normal weights if ITYPE = 0.

6: ABSCIS(N) -- DOUBLE PRECISION array Output
   On exit: the N abscissae.

7: GTYPE -- INTEGER Input
   On entry: The value of GTYPE indicates which quadrature
   formula are to be used:
   GTYPE = 0 for Gauss-Legendre weights and abscissae;
   GTYPE = 1 for Gauss-Rational weights and abscissae;
GTYPE = 2 for Gauss-Laguerre weights and abscissae;

GTYPE = 3 for Gauss-Hermite weights and abscissae.

8: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
The N-point rule is not among those stored. If the soft fail option is used, the weights and abscissae returned will be those for the largest valid value of N less than the requested value, and the excess elements of WEIGHT and ABSCIS (i.e., up to the requested N) will be filled with zeros.

IFAIL= 2
The value of A and/or B is invalid.
   Gauss-Rational: A + B = 0
   Gauss-Laguerre: B = 0
   Gauss-Hermite: B <= 0
If the soft fail option is used the weights and abscissae are returned as zero.

IFAIL= 3
Laguerre and Hermite normal weights only: underflow is occurring in evaluating one or more of the normal weights. If the soft fail option is used, the underflowing weights are returned as zero. A smaller value of N must be used; or adjusted weights should be used (ITYPE = 1). In the latter case, take care that underflow does not occur when evaluating the integrand appropriate for adjusted weights.

IFAIL=4
   GTYPE < 0 or GTYPE > 3

7. Accuracy

The weights and abscissae are stored for standard values of A and B to full machine accuracy.
8. Further Comments

Timing is negligible.

9. Example

This example program returns the abscissae and (adjusted) weights for the six-point Gauss-Laguerre formula.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

Multidimensional integrals with finite limits

--- nagd.ht ---

--- nagd.ht ---

D01FCF(3NAG)  Foundation Library (12/10/92)  D01FCF(3NAG)

D01 -- Quadrature
D01FCF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

D01FCF attempts to evaluate a multi-dimensional integral (up to 15 dimensions), with constant and finite limits, to a specified relative accuracy, using an adaptive subdivision strategy.
2. Specification

SUBROUTINE D01FCF (NDIM, A, B, MINPTS, MAXPTS, FUNCTN, 
1 EPS, ACC, LENWRK, WRKSTR, FINVAL, IFAIL)
INTEGER NDIM, MINPTS, MAXPTS, LENWRK, IFAIL
DOUBLE PRECISION A(NDIM), B(NDIM), FUNCTN, EPS, ACC, WRKSTR
1 (LENWRK), FINVAL
EXTERNAL FUNCTN

3. Description

The routine returns an estimate of a multi-dimensional integral over a hyper-rectangle (i.e., with constant limits), and also an estimate of the relative error. The user sets the relative accuracy required, supplies the integrand as a function subprogram (FUNCTN), and also sets the minimum and maximum acceptable number of calls to FUNCTN (in MINPTS and MAXPTS).

The routine operates by repeated subdivision of the hyper-rectangular region into smaller hyper-rectangles. In each subregion, the integral is estimated using a seventh-degree rule, and an error estimate is obtained by comparison with a fifth-degree rule which uses a subset of the same points. The fourth differences of the integrand along each co-ordinate axis are evaluated, and the subregion is marked for possible future subdivision in half along that co-ordinate axis which has the largest absolute fourth difference.

If the estimated errors, totalled over the subregions, exceed the requested relative error (or if fewer than MINPTS calls to FUNCTN have been made), further subdivision is necessary, and is performed on the subregion with the largest estimated error, that subregion being halved along the appropriate co-ordinate axis.

The routine will fail if the requested relative error level has not been attained by the time MAXPTS calls to FUNCTN have been made; or, if the amount LENWRK of working storage is insufficient. A formula for the recommended value of LENWRK is given in Section 5. If a smaller value is used, and is exhausted in the course of execution, the routine switches to a less efficient mode of operation; only if this mode also breaks down is insufficient storage reported.

D01FCF is based on the HALF subroutine developed by van Dooren and de Ridder [1]. It uses a different basic rule, described by Genz and Malik [2].

4. References

for Numerical Integration over an N-dimensional Cube. J.

Numerical Integration over an N-dimensional Rectangular

5. Parameters

1: NDIM -- INTEGER Input
   On entry: the number of dimensions of the integral, n.
   Constraint: 2 <= NDIM <= 15.

2: A(NDIM) -- DOUBLE PRECISION array Input
   On entry: the lower limits of integration, a , for
   i=1,2,...,n.

3: B(NDIM) -- DOUBLE PRECISION array Input
   On entry: the upper limits of integration, b , for
   i=1,2,...,n.

4: MINPTS -- INTEGER Input/Output
   On entry: MINPTS must be set to the minimum number of
   integrand evaluations to be allowed. On exit: MINPTS
   contains the actual number of integrand evaluations used by
   D01FCF.

5: MAXPTS -- INTEGER Input
   On entry: the maximum number of integrand evaluations to be
   allowed.
   Constraints:
   MAXPTS >= MINPTS
   MAXPTS >= (alpha),
   \[ \text{NDIM}^{2} + 2*\text{NDIM} + 2*\text{NDIM}+1. \]

6: FUNCTN -- DOUBLE PRECISION FUNCTION, supplied by the
   user.
   External Procedure
   FUNCTN must return the value of the integrand f at a given
   point.
   Its specification is:
   
   \[
   \text{DOUBLE PRECISION FUNCTION FUNCTN (NDIM,Z)}
   \]
   \[
   \text{INTEGER NDIM}
   \]
DOUBLE PRECISION Z(NDIM)

1: NDIM -- INTEGER  
   Input
   On entry: the number of dimensions of the integral, n.

2: Z(NDIM) -- DOUBLE PRECISION array  
   Input
   On entry: the co-ordinates of the point at which the
   integrand must be evaluated.

FUNCTN must be declared as EXTERNAL in the (sub)program
from which D01FCF is called. Parameters denoted as
Input must not be changed by this procedure.

7: EPS -- DOUBLE PRECISION  
   Input
   On entry: the relative error acceptable to the user. When
   the solution is zero or very small relative accuracy may not
   be achievable but the user may still set EPS to a reasonable
   value and check for the error exit IFAIL = 2. Constraint:
   EPS > 0.0.

8: ACC -- DOUBLE PRECISION  
   Output
   On exit: the estimated relative error in FINVAL.

9: LENWRK -- INTEGER  
   Input
   On entry:
   the dimension of the array WRKSTR as declared in the
   (sub)program from which D01FCF is called.
   Suggested value: for maximum efficiency, LENWRK >=
   (NDIM+2)*(1+MAXPTS/(alpha)) (see parameter MAXPTS for
   (alpha)).
   If LENWRK is less than this, the routine will usually run
   less efficiently and may fail. Constraint: LENWRK>=2*NDIM+4.

10: WRKSTR(LENWRK) -- DOUBLE PRECISION array  
    Workspace

11: FINVAL -- DOUBLE PRECISION  
    Output
    On exit: the best estimate obtained for the integral.

12: IFAIL -- INTEGER  
    Input/Output
    On entry: IFAIL must be set to 0, -1 or 1. Users who are
    unfamiliar with this parameter should refer to the Essential
    Introduction for details.
    On exit: IFAIL = 0 unless the routine detects an error or
    gives a warning (see Section 6).

For this routine, because the values of output parameters
may be useful even if IFAIL /=0 on exit, users are
recommended to set IFAIL to -1 before entry. It is then
essential to test the value of IFAIL on exit. To suppress
the output of an error message when soft failure occurs, set
6. Error Indicators and Warnings

Errors or warnings specified by the routine:

**IFAIL= 1**

- On entry NDIM < 2,
- or NDIM > 15,
- or MAXPTS is too small,
- or LENWRK<2*NDIM+4,
- or EPS <= 0.0.

**IFAIL= 2**

MAXPTS was too small to obtain the required relative accuracy EPS. On soft failure, FINVAL and ACC contain estimates of the integral and the relative error, but ACC will be greater than EPS.

**IFAIL= 3**

LENWRK was too small. On soft failure, FINVAL and ACC contain estimates of the integral and the relative error, but ACC will be greater than EPS.

7. Accuracy

A relative error estimate is output through the parameter ACC.

8. Further Comments

Execution time will usually be dominated by the time taken to evaluate the integrand FUNCTN, and hence the maximum time that could be taken will be proportional to MAXPTS.

9. Example

This example program estimates the integral

\[
\int \int \int \frac{4z}{1 + z + z^2} \exp(2z \cdot z) \, dz \, dz \, dz = 0.575364.
\]
The accuracy requested is one part in 10,000.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

---

Third-order finite-difference integration

--- nagd.ht ---

D01GAF integrates a function which is specified numerically at four or more points, over the whole of its specified range, using third-order finite-difference formulae with error estimates, according to a method due to Gill and Miller.

1. Purpose

D01GAF integrates a function which is specified numerically at four or more points, over the whole of its specified range, using third-order finite-difference formulae with error estimates, according to a method due to Gill and Miller.

2. Specification

SUBROUTINE D01GAF (X, Y, N, ANS, ER, IFAIL)
INTEGER N, IFAIL
DOUBLE PRECISION X(N), Y(N), ANS, ER
3. Description

This routine evaluates the definite integral

\[
\int_{x_1}^{x_n} y(x) \, dx, \nonumber
\]

where the function \(y\) is specified at the \(n\)-points \(x_1, x_2, \ldots, x_n\), which should be all distinct, and in either ascending or descending order. The integral between successive points is calculated by a four-point finite-difference formula centred on the interval concerned, except in the case of the first and last intervals, where four-point forward and backward difference formulae respectively are employed. If \(n\) is less than 4, the routine fails. An approximation to the truncation error is integrated and added to the result. It is also returned separately to give an estimate of the uncertainty in the result. The method is due to Gill and Miller.

4. References

5. Parameters

1: \(X(N)\) -- DOUBLE PRECISION array
   Input
   On entry: the values of the independent variable, i.e., the \(x, x, \ldots, x\). Constraint: either \(X(1) < X(2) < \ldots < X(N)\) or \(X(1) > X(2) > \ldots > X(N)\).

2: \(Y(N)\) -- DOUBLE PRECISION array
   Input
   On entry: the values of the dependent variable \(y\) at the \(i\) points \(x\), for \(i=1,2,\ldots,n\).

3: \(N\) -- INTEGER
   Input
   On entry: the number of points, \(n\). Constraint: \(N \geq 4\).

4: \(ANS\) -- DOUBLE PRECISION
   Output
   On exit: the estimate of the integral.
5: ER -- DOUBLE PRECISION
On exit: an estimate of the uncertainty in ANS.

6: IFAIL -- INTEGER
On entry: IFAIL must be set to 0, -1 or 1. For users not
familiar with this parameter (described in the Essential
Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see
Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
Indicates that fewer than four-points have been supplied to
the routine.

IFAIL= 2
Values of X are neither strictly increasing nor strictly
decreasing.

IFAIL= 3
Two points have the same X-value.

No error is reported arising from the relative magnitudes of ANS
and ER on return, due to the difficulty when the true answer is
zero.

7. Accuracy

No accuracy level is specified by the user before calling the
routine but on return ABS(ER) is an approximation to, but not
necessarily a bound for, |I-ANS|. If on exit IFAIL > 0, both ANS
and ER are returned as zero.

8. Further Comments

The time taken by the routine depends on the number of points
supplied, n.

In their paper, Gill and Miller [1] do not add the quantity ER to
ANS before return. However, extensive tests have shown that a
dramatic reduction in the error often results from such addition.
In other cases, it does not make an improvement, but these tend
to be cases of low accuracy in which the modified answer is not
significantly inferior to the unmodified one. The user has the
option of recovering the Gill-Miller answer by subtracting ER
from ANS on return from the routine.
9. Example

The example program evaluates the integral

\[
\int_{0}^{1} \frac{1}{1 + x} \, dx = \pi
\]

reading in the function values at 21 unequally-spaced points.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

Monte Carlo integration over hyper-rectangular regions

— nagd.ht —
D01GBF returns an approximation to the integral of a function over a hyper-rectangular region, using a Monte Carlo method. An approximate relative error estimate is also returned. This routine is suitable for low accuracy work.

### 2. Specification

```fortran
SUBROUTINE D01GBF (NDIM, A, B, MINCLS, MAXCLS, FUNCTN, 
1 EPS, ACC, LENWRK, WRKSTR, FINEST, IFAIL)
INTEGER NDIM, MINCLS, MAXCLS, LENWRK, IFAIL
DOUBLE PRECISION A(NDIM), B(NDIM), FUNCTN, EPS, ACC, WRKSTR 
1 (LENWRK), FINEST
EXTERNAL FUNCTN
```

### 3. Description

D01GBF uses an adaptive Monte Carlo method based on the algorithm described by Lautrup [1]. It is implemented for integrals of the form:

\[
\int_{a_1}^{b_1} \int_{a_2}^{b_2} \ldots \int_{a_n}^{b_n} f(x_1, x_2, \ldots, x_n) \, dx_n \ldots dx_2 \, dx_1.
\]

Upon entry, unless LENWRK has been set to the minimum value 10*NDIM, the routine subdivides the integration region into a number of equal volume subregions. Inside each subregion the integral and the variance are estimated by means of pseudo-random sampling. All contributions are added together to produce an estimate for the whole integral and total variance. The variance along each co-ordinate axis is determined and the routine uses this information to increase the density and change the widths of the sub-intervals along each axis, so as to reduce the total variance. The total number of subregions is then increased by a factor of two and the program recycles for another iteration. The program stops when a desired accuracy has been reached or too many integral evaluations are needed for the next cycle.

### 4. References

### 5. Parameters
1: **NDIM -- INTEGER**  
   Input  
   On entry: the number of dimensions of the integral, n.  
   Constraint: NDIM >= 1.

2: **A(NDIM) -- DOUBLE PRECISION array**  
   Input  
   On entry: the lower limits of integration, a , for  
   i = 1, 2, ..., n.

3: **B(NDIM) -- DOUBLE PRECISION array**  
   Input  
   On entry: the upper limits of integration, b , for  
   i = 1, 2, ..., n.

4: **MINCLS -- INTEGER**  
   Input/Output  
   On entry: MINCLS must be set:  
   either to the minimum number of integrand evaluations to be  
   allowed, in which case MINCLS >= 0;  
   or to a negative value. In this case the routine assumes  
   that a previous call had been made with the same parameters  
   NDIM, A and B and with either the same integrand (in which  
   case D01GBF continues calculation) or a similar integrand  
   (in which case D01GBF begins the calculation with the  
   subdivision used in the last iteration of the previous call)  
   . See also WRKSTR. On exit: MINCLS contains the number of  
   integrand evaluations actually used by D01GBF.

5: **MAXCLS -- INTEGER**  
   Input  
   On entry: the maximum number of integrand evaluations to be  
   allowed. In the continuation case this is the number of new  
   integrand evaluations to be allowed. These counts do not  
   include zero integrand values.  
   Constraints:  
   MAXCLS > MINCLS,  
   MAXCLS >= 4*(NDIM+1).

6: **FUNCTN -- DOUBLE PRECISION FUNCTION**, supplied by the user.  
   External Procedure  
   FUNCTN must return the value of the integrand f at a given  
   point.  
   Its specification is:  
   
   ```
   DOUBLE PRECISION FUNCTION FUNCTN (NDIM, X)
   INTEGER NDIM
   DOUBLE PRECISION X(NDIM)
   ```
22.3. NAGD.HT

1: NDIM -- INTEGER
   On entry: the number of dimensions of the integral, n.

2: X(NDIM) -- DOUBLE PRECISION array
   On entry: the co-ordinates of the point at which the
   integrand must be evaluated.

FUNCTN must be declared as EXTERNAL in the (sub)program
from which D01GBF is called. Parameters denoted as
Input must not be changed by this procedure.

7: EPS -- DOUBLE PRECISION
   On entry: the relative accuracy required. Constraint: EPS
   >= 0.0.

8: ACC -- DOUBLE PRECISION
   On exit: the estimated relative accuracy of FINEST.

9: LENWRK -- INTEGER
   On entry:
   the dimension of the array WRKSTR as declared in the
   (sub)program from which D01GBF is called.
   For maximum efficiency, LENWRK should be about
   1/NDIM
   3*NDIM*(MAXCLS/4) +7*NDIM.
   If LENWRK is given the value 10*NDIM then the subroutine
   uses only one iteration of a crude Monte Carlo method with
   MAXCLS sample points. Constraint: LENWRK >= 10*NDIM.

10: WRKSTR(LENWRK) -- DOUBLE PRECISION array
    On entry: if MINCLS<0, WRKSTR must be unchanged from the
    previous call of D01GBF - except that for a new integrand
    WRKSTR(LENWRK) must be set to 0.0. See also MINCLS. On
    exit: WRKSTR contains information about the current sub-
    interval structure which could be used in later calls of
    D01GBF. In particular, WRKSTR(j) gives the number of sub-
    intervals used along the jth co-ordinate axis.

11: FINEST -- DOUBLE PRECISION
    On exit: the best estimate obtained for the integral.

12: IFAIL -- INTEGER
    On entry: IFAIL must be set to 0, -1 or 1. Users who are
    unfamiliar with this parameter should refer to the Essential
    Introduction for details.

    On exit: IFAIL = 0 unless the routine detects an error or
    gives a warning (see Section 6).

For this routine, because the values of output parameters
may be useful even if IFAIL /=0 on exit, users are
recommended to set IFAIL to -1 before entry. It is then essential to test the value of IFAIL on exit. To suppress the output of an error message when soft failure occurs, set IFAIL to 1.

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

IFAIL= 1
On entry NDIM < 1,
or MINCLS >= MAXCLS,
or LENWRK < 10*NDIM,
or MAXCLS < 4*(NDIM+1),
or EPS < 0.0.

IFAIL= 2
MAXCLS was too small for D01GBF to obtain the required relative accuracy EPS. In this case D01GBF returns a value of FINEST with estimated relative error ACC, but ACC will be greater than EPS. This error exit may be taken before MAXCLS non-zero integrand evaluations have actually occurred, if the routine calculates that the current estimates could not be improved before MAXCLS was exceeded.

7. Accuracy

A relative error estimate is output through the parameter ACC. The confidence factor is set so that the actual error should be less than ACC 90% of the time. If a user desires a higher confidence level then a smaller value of EPS should be used.

8. Further Comments

The running time for D01GBF will usually be dominated by the time used to evaluate the integrand FUNCTN, so the maximum time that could be used is approximately proportional to MAXCLS.

For some integrands, particularly those that are poorly behaved in a small part of the integration region, D01GBF may terminate with a value of ACC which is significantly smaller than the actual relative error. This should be suspected if the returned value of MINCLS is small relative to the expected difficulty of the integral. Where this occurs, D01GBF should be called again, but with a higher entry value of MINCLS (e.g. twice the returned value) and the results compared with those from the previous
call.

The exact values of FINEST and ACC on return will depend (within statistical limits) on the sequence of random numbers generated within D01GBF by calls to G05CAF. Separate runs will produce identical answers unless the part of the program executed prior to calling D01GBF also calls (directly or indirectly) routines from Chapter G05, and the series of such calls differs between runs. If desired, the user may ensure the identity or difference between runs of the results returned by D01GBF, by calling G05CBF or G05CCF respectively, immediately before calling D01GBF.

9. Example

This example program calculates the integral

\[
\frac{4x \exp(2x)}{1 + (1+x^2)} = 0.575364.
\]

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

Ordinary Differential Equations

— nagd.ht —
CHAPTER 22. NAG LIBRARY ROUTINES

D02 -- Ordinary Differential Equations
Introduction -- D02
Chapter D02
Ordinary Differential Equations

1. Scope of the Chapter

This chapter is concerned with the numerical solution of ordinary
differential equations. There are two main types of problem,
those in which all boundary conditions are specified at one point
(initial-value problems), and those in which the boundary
conditions are distributed between two or more points (boundary-
value problems and eigenvalue problems). Routines are available
for initial-value problems, two-point boundary-value problems and
Sturm-Liouville eigenvalue problems.

2. Background to the Problems

For most of the routines in this chapter a system of ordinary
differential equations must be written in the form

\[ y'(x) = f(x, y_1, y_2, \ldots, y_n), \]
\[ y'(2) = f(x, y_1, y_2, \ldots, y_n), \]
\[ \ldots \]
\[ y'(n) = f(x, y_1, y_2, \ldots, y_n), \]

that is the system must be given in first-order form. The \( n \)
dependent variables (also, the solution) \( y_1, y_2, \ldots, y_n \) are
functions of the independent variable \( x \), and the differential
equations give expressions for the first derivatives \( y' = \frac{dy}{dx} \)
in terms of \( x \) and \( y_1, y_2, \ldots, y_n \). For a system of \( n \) first-order
\( y_1, y_2, \ldots, y_n \) equations, \( n \) associated boundary conditions are usually required
to define the solution.

A more general system may contain derivatives of higher order,
but such systems can almost always be reduced to the first-order
form by introducing new variables. For example, suppose we have
the third-order equation

\[ 2 \]
\[ z''' + z'' + k(1 - z') = 0. \]
We write \( y = z, \ y = z', \ y = z'' \), and the third order equation may then be written as the system of first-order equations

\[
\begin{align*}
    y' &= y_1 \\
    y' &= y_2 \\
    y' &= -y_2 y_3 - k(1-y_3).
\end{align*}
\]

For this system \( n = 3 \) and we require 3 boundary conditions in order to define the solution. These conditions must specify values of the dependent variables at certain points. For example, we have an initial-value problem if the conditions are:

\[
\begin{align*}
    y_1 &= 0 \quad \text{at } x=0 \\
    y_2 &= 0 \quad \text{at } x=0 \\
    y_3 &= 0.1 \quad \text{at } x=0.
\end{align*}
\]

These conditions would enable us to integrate the equations numerically from the point \( x=0 \) to some specified end-point. We have a boundary-value problem if the conditions are:

\[
\begin{align*}
    y_1 &= 0 \quad \text{at } x=0 \\
    y_2 &= 0 \quad \text{at } x=0 \\
    y_2 &= 1 \quad \text{at } x=10.
\end{align*}
\]

These conditions would be sufficient to define a solution in the range \( 0 \leq x \leq 10 \), but the problem could not be solved by direct integration (see Section 2.2). More general boundary conditions are permitted in the boundary-value case.

2.1. Initial-value Problems

To solve first-order systems, initial values of the dependent variables \( y_i \), for \( i=1,2,\ldots,n \) must be supplied at a given point,
a point, \( b \), at which the values of the dependent variables are required, must be specified. The numerical solution is then obtained by a step-by-step calculation which approximates values of the variables \( y_i \), for \( i=1,2,...,n \) at finite intervals over the required range \([a,b]\). The routines in this chapter adjust the step length automatically to meet specified accuracy tolerances. Although the accuracy tests used are reliable over each step individually, in general an accuracy requirement cannot be guaranteed over a long range. For many problems there may be no serious accumulation of error, but for unstable systems small perturbations of the solution will often lead to rapid divergence of the calculated values from the true values. A simple check for stability is to carry out trial calculations with different tolerances; if the results differ appreciably the system is probably unstable. Over a short range, the difficulty may possibly be overcome by taking sufficiently small tolerances, but over a long range it may be better to try to reformulate the problem.

A special class of initial-value problems are those for which the solutions contain rapidly decaying transient terms. Such problems are called stiff; an alternative way of describing them is to say that certain eigenvalues of the Jacobian matrix \( \frac{df}{dy} \) have large negative real parts when compared to others. These problems require special methods for efficient numerical solution; the methods designed for non-stiff problems when applied to stiff problems tend to be very slow, because they need small step lengths to avoid numerical instability. A full discussion is given in Hall and Watt [6] and a discussion of the methods for stiff problems is given in Berzins, Brankin and Gladwell [1].

2.2. Boundary-value Problems

A full discussion of the design of the methods and codes for boundary-value problems is given in Gladwell [4]. In general, a system of nonlinear differential equations with boundary conditions given at two or more points cannot be guaranteed to have a solution. The solution has to be determined iteratively (if it exists). Finite-difference equations are set up on a mesh of points and estimated values for the solution at the grid points are chosen. Using these estimated values as starting values a Newton iteration is used to solve the finite-difference equations. The accuracy of the solution is then improved by deferred corrections or the addition of points to the mesh or a combination of both. Good initial estimates of the solution may be required in some cases but results may be difficult to compute when the solution varies very rapidly over short ranges. A
22.3. NAGD.HT

discussion is given in Chapters 9 and 11 of Gladwell and Sayers [5] and Chapter 4 of Childs et al [2].

2.3. Eigenvalue Problems

Sturm-Liouville problems of the form

\[ (p(x)y')' + q(x,\lambda)y = 0 \]

with appropriate boundary conditions given at two points, can be solved by a Scaled Pruefer method. In this method the differential equation is transformed to another which can be solved for a specified eigenvalue by a shooting method. A discussion is given in Chapter 11 of Gladwell and Sayers [5] and a complete description is given in Pryce [7].

2.6. References

3. Recommendations on Choice and Use of Routines

There are no routines which deal directly with COMPLEX equations. These may however be transformed to larger systems of real equations of the required form. Split each equation into its real and imaginary parts and solve for the real and imaginary parts of each component of the solution. Whilst this process doubles the
size of the system and may not always be appropriate it does make available for use the full range of routines provided presently.

3.1. Initial-value Problems

For simple first-order problems with low accuracy requirements, that is problems on a short range of integration, with derivative functions \( f \) which are inexpensive to calculate and where only a few correct figures are required, the best routines to use are likely to be the Runge-Kutta-Merson (RK) routines, D02BBF and D02BHF. For larger problems, over long ranges or with high accuracy requirements the variable-order, variable-step Adams routine D02CJF should usually be preferred. For stiff equations, that is those with rapidly decaying transient solutions, the Backward Differentiation Formula (BDF) variable-order, variable-step routine D02EJF should be used.

There are four routines for initial-value problems, two of which use the Runge-Kutta-Merson method:

- **D02BBF** integrates a system of first order ordinary differential equations over a range with intermediate output and a choice of error control.
- **D02BHF** integrates a system of first order ordinary differential equations with a choice of error control until a position is determined where a function of the solution is zero.

one uses an Adams method:

- **D02CJF** combines the functionality of D02BBF and D02BHF.

and one uses a BDF method:

- **D02EJF** combines the functionality of D02BBF and D02BHF.

3.2. Boundary-value Problems

D02GAF may be used for simple boundary-value problems with assigned boundary values. The user may find that convergence is difficult to achieve using D02GAF since only specifying the unknown boundary values and the position of the finite-difference mesh is permitted. In such cases the user may use D02RAF which permits specification of an initial estimate for the solution at all mesh points and allows the calculation to be influenced in other ways too. D02RAF is designed to solve a general nonlinear two-point boundary value problem with nonlinear boundary conditions.
A routine, D02GBF, is also supplied specifically for the general linear two-point boundary-value problem written in a standard

The user is advised to use interpolation routines from the E01 Chapter to obtain solution values at points not on the final mesh.

3.3. Eigenvalue Problems

There is one general purpose routine for eigenvalue problems, D02KEF. It may be used to solve regular or singular second-order Sturm-Liouville problems on a finite or infinite range. Discontinuous coefficient functions can be treated and eigenfunctions can be computed.

D02 -- Ordinary Differential Equations

Ordinary Differential Equations

D02BBF ODEs, IVP, Runge-Kutta-Merson method, over a range, intermediate output

D02BHF ODEs, IVP, Runge-Kutta-Merson method, until function of solution is zero

D02CJF ODEs, IVP, Adams method, until function of solution is zero, intermediate output

D02EJF ODEs, stiff IVP, BDF method, until function of solution is zero, intermediate output

D02GAF ODEs, boundary value problem, finite difference technique with deferred correction, simple nonlinear problem

D02GBF ODEs, boundary value problem, finite difference technique with deferred correction, general linear problem

D02KEF 2nd order Sturm-Liouville problem, regular/singular system, finite/infinite range, eigenvalue and eigenfunction, user-specified break-points

D02RAF ODEs, general nonlinear boundary value problem, finite difference technique with deferred correction, continuation facility
First-order ODE over an interval with initial conditions

--- nagd.ht ---

--- nagd.ht ---

--- nagd.ht ---
The routine integrates a system of ordinary differential equations

\[ y' = f(x, y_1, y_2, \ldots, y_n) \quad i = 1, 2, \ldots, n \]

from \( x = X \) to \( x = X_{\text{END}} \) using a Merson form of the Runge-Kutta method. The system is defined by a subroutine FCN supplied by the user, which evaluates \( f \) in terms of \( x \) and \( y_1, y_2, \ldots, y_n \), and the values of \( y_1, y_2, \ldots, y_n \) must be given at \( x = X \).

The solution is returned via the user-supplied routine OUTPUT at a set of points specified by the user. This solution is obtained by quintic Hermite interpolation on solution values produced by the Runge-Kutta method.

The accuracy of the integration and, indirectly, the interpolation is controlled by the parameters TOL and IRELAB.

For a description of Runge-Kutta methods and their practical implementation see Hall and Watt [1].

4. References

5. Parameters

1: \( X \) -- DOUBLE PRECISION  
   Input/Output
   On entry: \( X \) must be set to the initial value of the independent variable \( x \). On exit: \( X_{\text{END}} \), unless an error has occurred, when it contains the value of \( x \) at the error.

2: \( X_{\text{END}} \) -- DOUBLE PRECISION  
   Input
   On entry: the final value of the independent variable. If \( X_{\text{END}} < X \) on entry, integration will proceed in a negative direction.

3: \( M \) -- INTEGER  
   Input
   On entry: the first dimension of the array RESULT. This will usually be equal to the number of points at which the solution is required.
   Constraint: \( M > 0 \).

4: \( N \) -- INTEGER  
   Input
   On entry: the number of differential equations.
   Constraint: \( N > 0 \).
5: Y(N) -- DOUBLE PRECISION array
On entry: the initial values of the solution y , y , ..., y .
1 2 n
On exit: the computed values of the solution at the final value of X.

6: TOL -- DOUBLE PRECISION
On entry: TOL must be set to a positive tolerance for controlling the error in the integration.

D02BBF has been designed so that, for most problems, a reduction in TOL leads to an approximately proportional reduction in the error in the solution at XEND. The relation between changes in TOL and the error at intermediate output points is less clear, but for TOL small enough the error at intermediate output points should also be approximately proportional to TOL. However, the actual relation between TOL and the accuracy achieved cannot be guaranteed. The user is strongly recommended to call D02BBF with more than one value for TOL and to compare the results obtained to estimate their accuracy. In the absence of any prior knowledge, the user might compare the results obtained by calling D02BBF with TOL=10.0 and TOL=10.0 if p correct decimal digits in the solution are required. Constraint: TOL > 0.0. On exit: normally unchanged. However if the range X to XEND is so short that a small change in TOL is unlikely to make any change in the computed solution then, on return, TOL has its sign changed. This should be treated as a warning that the computed solution is likely to be more accurate than would be produced by using the same value of TOL on a longer range of integration.

7: IRELAB -- INTEGER
On entry: IRELAB determines the type of error control. At each step in the numerical solution an estimate of the local error, EST, is made. For the current step to be accepted the following condition must be satisfied:

IRELAB = 0
EST = 10.0 <= TOL * max{1.0, |y|, |y|, ..., |y|};
1 2 n

IRELAB = 1
EST <= TOL;

IRELAB = 2
EST <= TOL * max{(epsilon), |y|, |y|, ..., |y|}, where
1 2 n
(epsilon) is machine precision.
If the appropriate condition is not satisfied, the step size is reduced and the solution is recomputed on the current step.

If the user wishes to measure the error in the computed solution in terms of the number of correct decimal places, then IRELAB should be given the value 1 on entry, whereas if the error requirement is in terms of the number of correct significant digits, then IRELAB should be given the value 2. Where there is no preference in the choice of error test IRELAB = 0 will result in a mixed error test. Constraint: \(0 \leq \text{IRELAB} \leq 2\).

8: RESULT(M,N) -- DOUBLE PRECISION array

On exit: the computed values of the solution at the points given by OUTPUT.

9: FCN -- SUBROUTINE, supplied by the user.

External Procedure

FCN must evaluate the functions \(f\) (i.e., the derivatives \(i\)) for given values of its arguments \(x,y,\ldots,y\).

\[
\begin{align*}
\text{SUBROUTINE FCN (X, Y, F)} \\
\text{DOUBLE PRECISION X, Y(n), F(n)}
\end{align*}
\]

where \(n\) is the actual value of \(N\) in the call of D02BBF.

1: X -- DOUBLE PRECISION

Input

On entry: the value of the argument \(x\).

2: Y(*) -- DOUBLE PRECISION array

Input

On entry: the value of the argument \(y\), for \(i=1,2,\ldots,n\).

3: F(*) -- DOUBLE PRECISION array

Output

On exit: the value of \(f\), for \(i=1,2,\ldots,n\).

FCN must be declared as EXTERNAL in the (sub)program from which D02BBF is called. Parameters denoted as Input must not be changed by this procedure.

10: OUTPUT -- SUBROUTINE, supplied by the user.

External Procedure

OUTPUT allows the user to have access to intermediate values of the computed solution at successive points specified by the
user. These solution values may be returned to the user via the array RESULT if desired (this is a non-standard feature added for use with the Axiom system). OUTPUT is initially called by D02BBF with XSOL = X (the initial value of x). The user must reset XSOL to the next point where OUTPUT is to be called, and so on at each call to OUTPUT. If, after a call to OUTPUT, the reset point XSOL is beyond XEND, D02BBF will integrate to XEND with no further calls to OUTPUT; if a call to OUTPUT is required at the point XSOL = XEND, then XSOL must be given precisely the value XEND.

Its specification is:

```
SUBROUTINE OUTPUT(XSOL,Y,COUNT,M,N,RESULT)
  DOUBLE PRECISION Y(N),RESULT(M,N),XSOL
  INTEGER M,N,COUNT
1: XSOL -- DOUBLE PRECISION Input/Output
   On entry: the current value of the independent variable x. On exit: the next value of x at which OUTPUT is to be called.
2: Y(N) -- DOUBLE PRECISION array Input
   On entry: the computed solution at the point XSOL.
3: COUNT -- INTEGER Input/Output
   On entry: Zero if OUTPUT has not been called before, or the previous value of COUNT.
   On exit: A new value of COUNT: this can be used to keep track of the number of times OUTPUT has been called.
4: M -- INTEGER Input
   On entry: The first dimension of RESULT.
5: N -- INTEGER Input
   On entry: The dimension of Y.
6: RESULT(M,N) -- DOUBLE PRECISION array Input/Output
   On entry: the previous contents of RESULT.
   On exit: RESULT may be used to return the values of the intermediate solutions to the user.
OUTPUT must be declared as EXTERNAL in the (sub)program from which D02BBF is called. Parameters denoted as Input must not be changed by this procedure.
11: W(N,7) -- DOUBLE PRECISION array Workspace
12: IFAIL -- INTEGER Input/Output
   On entry: IFAIL must be set to 0, -1 or 1. For users not
familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
On entry TOL \leq 0,
or N \leq 0,
or IRELAB \neq 0, 1 or 2.

IFAIL= 2
With the given value of TOL, no further progress can be made across the integration range from the current point \( x = X \), or the dependence of the error on TOL would be lost if further progress across the integration range were attempted (see Section 8 for a discussion of this error exit). The components \( Y(1), Y(2), \ldots, Y(n) \) contain the computed values of the solution at the current point \( x = X \).

IFAIL= 3
TOL is too small for the routine to take an initial step (see Section 8). X and \( Y(1), Y(2), \ldots, Y(n) \) retain their initial values.

IFAIL= 4
\( X = XEND \) and XSOL \neq X after the initial call to OUTPUT.

IFAIL= 5
A value of XSOL returned by OUTPUT lies behind the previous value of XSOL in the direction of integration.

IFAIL= 6
A serious error has occurred in an internal call to D02PAF(*). Check all subroutine calls and array dimensions. Seek expert help.

IFAIL= 7
A serious error has occurred in an internal call to D02XAF(*). Check all subroutine calls and array dimensions. Seek expert help.

7. Accuracy
The accuracy depends on TOL, on the mathematical properties of the differential system, on the length of the range of integration and on the method. It can be controlled by varying TOL but the approximate proportionality of the error to TOL holds only for a restricted range of values of TOL. For TOL too large, the underlying theory may break down and the result of varying TOL may be unpredictable. For TOL too small, rounding errors may affect the solution significantly and an error exit with IFAIL = 2 or IFAIL = 3 is possible.

At the intermediate output points the same remarks apply. For large values of TOL it is possible that the errors at some intermediate output points may be much larger than at XEND. In any case, it must not be expected that the error will have the same size at all output points. At any point, it is a combination of the errors arising from the integration of the differential equation and the interpolation. The effect of combining these errors will vary, though in most cases the integration error will dominate.

The user who requires a more reliable estimate of the accuracy achieved than can be obtained by varying TOL, is recommended to call D02BDF(*) where both the solution and a global error estimate are computed.

8. Further Comments

The time taken by the routine depends on the complexity and mathematical properties of the system of differential equations defined by FCN, on the range, the tolerance and the number of calls to OUTPUT. There is also an overhead of the form $a+b*n$ where $a$ and $b$ are machine-dependent computing times.

If the routine fails with IFAIL = 3, then it can be called again with a larger value of TOL (if this has not already been tried). If the accuracy requested is really needed and cannot be obtained with this routine, the system may be very stiff (see below) or so badly scaled that it cannot be solved to the required accuracy.

If the routine fails with IFAIL = 2, it is probable that it has been called with a value of TOL which is so small that the solution cannot be obtained on the range $X$ to XEND. This can happen for well-behaved systems and very small values of TOL. The user should, however, consider whether there is a more fundamental difficulty. For example:

(a) in the region of a singularity (infinite value) of the solution, the routine will usually stop with IFAIL = 2, unless overflow occurs first. If overflow occurs using D02BBF, D02PAF(*) can be used instead to trap the
increasing solution before overflow occurs. In any case, numerical integration cannot be continued through a singularity, and analytic treatment should be considered;

(b) for 'stiff' equations, where the solution contains rapidly decaying components, the routine will use very small steps in x (internally to D02BBF) to preserve stability. This will usually exhibit itself by making the computing time excessively long, or occasionally by an exit with IFAIL = 2. Merson’s method is not efficient in such cases, and the user should try using D02EBF(*) (Backward Differentiation Formula). To determine whether a problem is stiff, D02BDF(*) may be used.

For well-behaved systems with no difficulties such as stiffness or singularities, the Merson method should work well for low accuracy calculations (three or four figures). For higher accuracy calculations or where FCN is costly to evaluate, Merson’s method may not be appropriate and a computationally less expensive method may be D02CBF(*) which uses an Adams method.

Users with problems for which D02BBF is not sufficiently general should consider using D02PAF(*) with D02XAF(*). D02PAF(*) is a more general Merson routine with many facilities including more general error control options and several criteria for interrupting the calculations. D02XAF(*) interpolates on values produced by D02PAF(*).

9. Example

To integrate the following equations (for a projectile)

\[ y' = \tan(\phi) \]
\[ -0.032\tan(\phi) \quad 0.02v \]
\[ v' = -\frac{0.032}{v} \cos(\phi) \]
\[ (\phi)' = -\frac{2}{v} \]

over an interval \( X = 0.0 \) to \( XEND = 8.0 \), starting with values \( y=0.0, v=0.5 \) and \( \phi=(\pi)/5 \) and printing the solution at steps of 1.0. We write \( y=Y(1), v=Y(2) \) and \( \phi=Y(3) \), and we set TOL=1.0E-4 and TOL=1.0E-5 in turn so that we may compare the solutions. The value of \( \pi \) is obtained by using X01AAF(*).
Note the careful construction of routine OUT to ensure that the value of XEND is printed.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

---

First-order ODE with initial conditions and user function

---

```
D02BHF(3NAG) Foundation Library (12/10/92) D02BHF(3NAG)

D02 -- Ordinary Differential Equations            D02BHF
D02BHF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

D02BHF integrates a system of first-order ordinary differential equations over an interval with suitable initial conditions, using a Runge-Kutta-Merson method, until a user-specified function of the solution is zero.

2. Specification

```
SUBROUTINE D02BHF (X, XEND, N, Y, TOL, IRELAB, HMAX, FCN,
                      1 G, W, IFAIL)

INTEGER N, IRELAB, IFAIL
DOUBLE PRECISION X, XEND, Y(N), TOL, HMAX, G, W(N,7)```
3. Description

The routine advances the solution of a system of ordinary
differential equations

\[ y' = f (x, y_1, y_2, \ldots, y_n), \quad i = 1, 2, \ldots, n, \]

from \( x = X \) towards \( x = X_{\text{END}} \) using a Merson form of the Runge-
Kutta method. The system is defined by a subroutine FCN supplied
by the user, which evaluates \( f \) in terms of \( x \) and \( y_1, y_2, \ldots, y_n \)
(see Section 5), and the values of \( y_1, y_2, \ldots, y_n \) must be given at
\( x = X \).

As the integration proceeds, a check is made on the function
\( g(x,y) \) specified by the user, to determine an interval where it
changes sign. The position of this sign change is then determined
accurately by interpolating for the solution and its derivative.

The accuracy of the integration and, indirectly, of the
determination of the position where \( g(x,y) = 0 \), is controlled by
the parameter TOL.

The accuracy of the integration and, indirectly, of the
determination of the position where \( g(x,y) = 0 \), is controlled by
the parameter TOL.

For a description of Runge-Kutta methods and their practical
implementation see Hall and Watt [1].

4. References

5. Parameters

1: X -- DOUBLE PRECISION  
Input/Output
On entry: X must be set to the initial value of the
independent variable x. On exit: the point where \( g(x,y) = 0 \).
0 unless an error has occurred, when it contains the value
of x at the error. In particular, if \( g(x,y) /= 0.0 \) anywhere on
the range X to XEND, it will contain XEND on exit.

2: XEND -- DOUBLE PRECISION  
Input
On entry: the final value of the independent variable x.
If XEND < X on entry, integration proceeds in a negative direction.

3: N -- INTEGER  
   Input
   On entry: the number of differential equations, n.
   Constraint: N > 0.

4: Y(N) -- DOUBLE PRECISION array  
   Input/Output
   On entry: the initial values of the solution y_1, y_2, ..., y_n.
   On exit: the computed values of the solution at the final point x = X.

5: TOL -- DOUBLE PRECISION  
   Input/Output
   On entry: TOL must be set to a positive tolerance for controlling the error in the integration and in the determination of the position where g(x,y) = 0.0.

   D02BHF has been designed so that, for most problems, a reduction in TOL leads to an approximately proportional reduction in the error in the solution obtained in the integration. The relation between changes in TOL and the error in the determination of the position where g(x,y) = 0.0 is less clear, but for TOL small enough the error should be approximately proportional to TOL. However, the actual relation between TOL and the accuracy cannot be guaranteed. The user is strongly recommended to call D02BHF with more than one value for TOL and to compare the results obtained to estimate their accuracy. In the absence of any prior knowledge the user might compare results obtained by calling D02BHF with TOL=10.0 and TOL=10.0 if p correct decimal digits in the solution are required. Constraint: TOL > 0.0.

   On exit: normally unchanged. However if the range from x = X to the position where g(x,y) = 0.0 (or to the final value of x if an error occurs) is so short that a small change in TOL is unlikely to make any change in the computed solution, then TOL is returned with its sign changed. To check results returned with TOL < 0.0, D02BHF should be called again with a positive value of TOL whose magnitude is considerably smaller than that of the previous call.

6: IRELAB -- INTEGER  
   Input
   On entry: IRELAB determines the type of error control. At each step in the numerical solution an estimate of the local error, EST, is made. For the current step to be accepted the following condition must be satisfied:

   IRELAB = 0
   EST <= TOL * max{1.0, |y_1|, |y_2|, ..., |y_n|};
IRELAB = 1
EST <= TOL;

IRELAB = 2
EST <= TOL*max\{(epsilon),|y_1|,|y_2|,...,|y_n|\},

where (epsilon) is machine precision.
If the appropriate condition is not satisfied, the step size
is reduced and the solution recomputed on the current step.

If the user wishes to measure the error in the computed
solution in terms of the number of correct decimal places,
then IRELAB should be given the value 1 on entry, whereas if
the error requirement is in terms of the number of correct
significant digits, then IRELAB should be given the value 2.
Where there is no preference in the choice of error test,
IRELAB = 0 will result in a mixed error test. It should be
borne in mind that the computed solution will be used in
evaluating g(x,y). Constraint: 0 <= IRELAB <= 2.

7: HMAX -- DOUBLE PRECISION Input
On entry: if HMAX = 0.0, no special action is taken.
If HMAX /= 0.0, a check is made for a change in sign of
g(x,y) at steps not greater than |HMAX|. This facility
should be used if there is any chance of 'missing' the
change in sign by checking too infrequently. For example, if
two changes of sign of g(x,y) are expected within a distance
h, say, of each other, then a suitable value for HMAX might
be HMAX = h/2. If only one change of sign in g(x,y) is
expected on the range X to XEND, then the choice HMAX = 0.0
is most appropriate.

8: FCN -- SUBROUTINE, supplied by the user. External Procedure
FCN must evaluate the functions f (i.e., the derivatives
\[ y'_i \] ) for given values of its arguments \[ x, y_1, ..., y_n \].

Its specification is:

\begin{verbatim}
SUBROUTINE FCN (X, Y, F)
    DOUBLE PRECISION X, Y(n), F(n)
\end{verbatim}

1: X -- DOUBLE PRECISION Input
On entry: the value of the argument x.
2: Y(*) -- DOUBLE PRECISION array Input
   On entry: the value of the argument $y_i$, for $i = 1, 2, \ldots, n$.

3: F(*) -- DOUBLE PRECISION array Output
   On exit: the value of $f_i$, for $i = 1, 2, \ldots, n$.
   FCN must be declared as EXTERNAL in the (sub)program from which D02BHF is called. Parameters denoted as Input must not be changed by this procedure.

9: G -- DOUBLE PRECISION FUNCTION, supplied by the user.
    External Procedure
    G must evaluate the function $g(x,y)$ at a specified point.
    Its specification is:
    
    DOUBLE PRECISION FUNCTION G (X, Y)
    DOUBLE PRECISION X, Y(n)
    where $n$ is the actual value of N in the call of D02BHF.

10: W(N,7) -- DOUBLE PRECISION array Workspace

11: IFAIL -- INTEGER Input/Output
    On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
    On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
   On entry TOL <= 0.0,
or \( N \leq 0 \),
or \( \text{IRELAB} \neq 0, 1 \) or 2.

**IFAIL= 2**

With the given value of TOL, no further progress can be made across the integration range from the current point \( x = X \), or dependence of the error on TOL would be lost if further progress across the integration range were attempted (see Section 8 for a discussion of this error exit). The components \( Y(1), Y(2), \ldots, Y(n) \) contain the computed values of the solution at the current point \( x = X \). No point at which \( g(x,y) \) changes sign has been located up to the point \( x = X \).

**IFAIL= 3**

TOL is too small for the routine to take an initial step (see Section 8). \( x \) and \( Y(1), Y(2), \ldots, Y(n) \) retain their initial values.

**IFAIL= 4**

At no point in the range \( X \) to \( XEND \) did the function \( g(x,y) \) change sign. It is assumed that \( g(x,y) = 0.0 \) has no solution.

**IFAIL= 5**

A serious error has occurred in an internal call to C05AZF(*). Check all subroutine calls and array dimensions. Seek expert help.

**IFAIL= 6**

A serious error has occurred in an internal call to D02PAF(*). Check all subroutine calls and array dimensions. Seek expert help.

**IFAIL= 7**

A serious error has occurred in an internal call to D02XAF(*). Check all subroutine calls and array dimensions. Seek expert help.

7. Accuracy

The accuracy depends on TOL, on the mathematical properties of the differential system, on the position where \( g(x,y) = 0.0 \) and on the method. It can be controlled by varying TOL but the approximate proportionality of the error to TOL holds only for a restricted range of values of TOL. For TOL too large, the underlying theory may break down and the result of varying TOL may be unpredictable. For TOL too small, rounding error may affect the solution significantly and an error exit with IFAIL = 2 or IFAIL = 3 is possible.
The accuracy may also be restricted by the properties of \( g(x,y) \).
The user should try to code \( G \) without introducing any unnecessary
cancellation errors.

8. Further Comments

The time taken by the routine depends on the complexity and
mathematical properties of the system of differential equations
defined by FCN, the complexity of \( G \), on the range, the position
of the solution and the tolerance. There is also an overhead of
the form \( a+b*n \) where \( a \) and \( b \) are machine-dependent computing
times.

For some problems it is possible that D02BHF will return IFAIL = 4
because of inaccuracy of the computed values \( Y \), leading to
inaccuracy in the computed values of \( g(x,y) \) used in the search
for the solution of \( g(x,y) = 0.0 \). This difficulty can be overcome
by reducing TOL sufficiently, and if necessary, by choosing HMAX
sufficiently small. If possible, the user should choose XEND well
beyond the expected point where \( g(x,y) = 0.0 \); for example make
\(|XEND-X|\) about 50 larger than the expected range. As a simple
check, if, with XEND fixed, a change in TOL does not lead to a
significant change in \( Y \) at XEND, then inaccuracy is not a likely
source of error.

If the routine fails with IFAIL = 3, then it could be called
again with a larger value of TOL if this has not already been
tried. If the accuracy requested is really needed and cannot be
obtained with this routine, the system may be very stiff (see
below) or so badly scaled that it cannot be solved to the
required accuracy.

If the routine fails with IFAIL = 2, it is likely that it has
been called with a value of TOL which is so small that a solution
cannot be obtained on the range \( X \) to XEND. This can happen for
well-behaved systems and very small values of TOL. The user
should, however, consider whether there is a more fundamental
difficulty. For example:

(a) in the region of a singularity (infinite value) of the
solution, the routine will usually stop with IFAIL = 2,
unless overflow occurs first. If overflow occurs using
D02BHF, D02PAF(*) can be used instead to trap the
increasing solution, before overflow occurs. In any case,
umerical integration cannot be continued through a
singularity, and analytical treatment should be considered;

(b) for 'stiff' equations, where the solution contains rapidly
decaying components, the routine will compute in very small
steps in $x$ (internally to D02BHF) to preserve stability. This will usually exhibit itself by making the computing
time excessively long, or occasionally by an exit with
IFAIL = 2. Merson's method is not efficient in such cases,
and the user should try D02EZF(*) which uses a Backward
Differentiation Formula method. To determine whether a
problem is stiff, D02EZF(*) may be used.

For well-behaved systems with no difficulties such as stiffness
or singularities, the Merson method should work well for low
accuracy calculations (three or four figures). For high accuracy
calculations or where FCN is costly to evaluate, Merson's method
may not be appropriate and a computationally less expensive
method may be D02CHF(*) which uses an Adams method.

For problems for which D02BHF is not sufficiently general, the
user should consider D02PAF(*). D02PAF(*) is a more general
Merson routine with many facilities including more general error
control options and several criteria for interrupting the
calculations. D02PAF(*) can be combined with the rootfinder
C05AZF(*) and the interpolation routine D02XAF(*) to solve
equations involving $y_1, y_2, \ldots, y_n$ and their derivatives.

D02BHF can also be used to solve an equation involving $x,$
$y_1, y_2, \ldots, y_n$ and the derivatives of $y_1, y_2, \ldots, y_n$. For example in
Section 9, D02BHF is used to find a value of $X > 0.0$ where $y(1) = 0.0$. It could instead be used to find a turning-point of $y_1$
 replacing the function $g(x,y)$ in the program by:

```
DOUBLE PRECISION FUNCTION G(X,Y)
DOUBLE PRECISION X,Y(3),F(3)
CALL FCN(X,Y,F)
G = F(1)
RETURN
END
```

This routine is only intended to locate the first zero of $g(x,y)$. If later zeros are required, users are strongly advised to
construct their own more general root finding routines as
discussed above.

9. Example

To find the value $X > 0.0$ at which $y=0.0$, where $y, v, (phi)$ are
defined by

$$y' = \tan(\phi)$$
\[ v' = \frac{-0.032 \tan(\phi)}{v \cos(\phi)} \]
\[ (\phi)' = \frac{-0.032}{2v} \]

and where at \( X = 0.0 \) we are given \( y=0.5, v=0.5 \) and \( (\phi) = \frac{\pi}{5} \). We write \( y=Y(1), v=Y(2) \) and \( (\phi)=Y(3) \) and we set \( TOL = 1.0E^{-4} \) and \( TOL = 1.0E^{-5} \) in turn so that we can compare the solutions. We expect the solution \( X \approx 7.3 \) and so we set \( XEND = 10.0 \) to avoid determining the solution of \( y=0.0 \) too near the end of the range of integration. The value of \( \pi \) is obtained by using X01AAF(*)

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

Note for users via the Axiom system: the interface to this routine has been enhanced for use with Axiom and is slightly different to that offered in the standard version of the Foundation Library.

1. Purpose

D02CJF integrates a system of first-order ordinary differential equations over a range with suitable initial conditions, using a variable-order, variable-step Adams method until a user-specified function, if supplied, of the solution is zero, and returns the solution at points specified by the user, if desired.

2. Specification

```fortran
SUBROUTINE D02CJF (X, XEND, M, N, Y, FCN, TOL, RELABS, 1
RESULT, OUTPUT, G, W, IFAIL)
INTEGER M, N, IFAIL
DOUBLE PRECISION X, XEND, Y(N), TOL, G, W(28+21*N), RESULT(M,N)
CHARACTER*1 RELABS
EXTERNAL FCN, OUTPUT, G
```

3. Description

The routine advances the solution of a system of ordinary differential equations

\[ y' = f(x, y_1, y_2, \ldots, y_n), \quad i = 1, 2, \ldots, n, \]

from \( x = X \) to \( x = XEND \) using a variable-order, variable-step Adams method. The system is defined by a subroutine FCN supplied by the user, which evaluates \( f \) in terms of \( x \) and \( y_1, y_2, \ldots, y_n \).

The initial values of \( y_1, y_2, \ldots, y_n \) must be given at \( x = X \).

The solution is returned via the user-supplied routine OUTPUT at points specified by the user, if desired: this solution is obtained by C interpolation on solution values produced by the user. As the integration proceeds a check can be made on the user-specified function \( g(x, y) \) to determine an interval where it changes sign. The position of this sign change is then determined accurately by C interpolation to the solution. It is assumed that \( g(x, y) = 0.0 \) can be determined by searching for a
change in sign in \( g(x,y) \). The accuracy of the integration, the interpolation and, indirectly, of the determination of the position where \( g(x,y)=0.0 \), is controlled by the parameters \( TOL \) and \( RELABS \).

For a description of Adams methods and their practical implementation see Hall and Watt [1].

4. References

5. Parameters

1: \( X \) -- DOUBLE PRECISION  
   Input/Output
   On entry: the initial value of the independent variable \( x \).
   Constraint: \( X \neq XEND \). On exit: if \( g \) is supplied by the user, it contains the point where \( g(x,y)=0.0 \), unless \( g(x,y)/=0.0 \) anywhere on the range \( X \) to \( XEND \), in which case, \( X \) will contain \( XEND \). If \( g \) is not supplied by the user it contains \( XEND \), unless an error has occurred, when it contains the value of \( x \) at the error.

2: \( XEND \) -- DOUBLE PRECISION  
   Input
   On entry: the final value of the independent variable. If \( XEND < X \), integration proceeds in the negative direction.
   Constraint: \( XEND \neq X \).

3: \( M \) -- INTEGER  
   Input
   On entry: the first dimension of the array RESULT. This will usually be equal to the number of points at which the solution is required.
   Constraint: \( M > 0 \).

4: \( N \) -- INTEGER  
   Input
   On entry: the number of differential equations.
   Constraint: \( N \geq 1 \).

5: \( Y(N) \) -- DOUBLE PRECISION array  
   Input/Output
   On entry: the initial values of the solution \( y_1, y_2, \ldots, y_n \) at \( x = X \). On exit: the computed values of the solution at the final point \( x = X \).

6: FCN -- SUBROUTINE, supplied by the user.  
   External Procedure
   FCN must evaluate the functions \( f \) (i.e., the derivatives \( y' \)) for given values of their arguments \( x, y, y_1, y_2, \ldots, y_n \).
Its specification is:

```fortran
SUBROUTINE FCN (X, Y, F)
DOUBLE PRECISION X, Y(n), F(n)
```

where \( n \) is the actual value of \( N \) in the call of D02CJF.

1: \( X \) -- DOUBLE PRECISION
   Input
   On entry: the value of the independent variable \( x \).

2: \( Y(*) \) -- DOUBLE PRECISION array
   Input
   On entry: the value of the variable \( y \), for
   \[ i = 1, 2, \ldots, n. \]

3: \( F(*) \) -- DOUBLE PRECISION array
   Output
   On exit: the value of \( f \), for \( i = 1, 2, \ldots, n. \)

FCN must be declared as EXTERNAL in the (sub)program
from which D02CJF is called. Parameters denoted as
Input must not be changed by this procedure.

7: \( TOL \) -- DOUBLE PRECISION
   Input
   On entry: a positive tolerance for controlling the error in
   the integration. Hence \( TOL \) affects the determination of the
   position where \( g(x,y)=0.0 \), if \( g \) is supplied.

D02CJF has been designed so that, for most problems, a
reduction in \( TOL \) leads to an approximately proportional
reduction in the error in the solution. However, the actual
relation between \( TOL \) and the accuracy achieved cannot be
guaranteed. The user is strongly recommended to call D02CJF
with more than one value for \( TOL \) and to compare the results
obtained to estimate their accuracy. In the absence of any
prior knowledge, the user might compare the results obtained

\[
\sum_{i=1}^{n} \left| \frac{E_{\text{est}}}{(\tau)^2} \right| \leq 1.0
\]

by calling D02CJF with \( TOL=10.0 \) and \( TOL=10.0 \) where \( p \)
correct decimal digits are required in the solution.
Constraint: \( TOL > 0.0 \).

8: \( \text{RELABS} \) -- CHARACTER*1
   Input
   On entry: the type of error control. At each step in the
   numerical solution an estimate of the local error, \( E_{\text{est}} \), is
   made. For the current step to be accepted the following
   condition must be satisfied:

\[
\sum_{i=1}^{n} \frac{E_{\text{est}}}{(\tau)^2} \leq 1.0
\]
where (tau) and (tau) are defined by

\[
\begin{align*}
\text{RELABS} & \quad \text{(tau)} & \quad \text{(tau)} \\
\text{r} & \quad \text{a} & \quad \text{r} & \quad \text{a} \\
'M' & \quad \text{TOL} & \quad \text{TOL} \\
'A' & \quad 0.0 & \quad \text{TOL} \\
'R' & \quad \text{TOL} & \quad (\text{epsilon}) \\
'D' & \quad \text{TOL} & \quad \text{TOL} \\
\end{align*}
\]

where (epsilon) is a small machine-dependent number and \( e_i \) is an estimate of the local error at \( y_i \), computed internally. If the appropriate condition is not satisfied, the step size is reduced and the solution is recomputed on the current step. If the user wishes to measure the error in the computed solution in terms of the number of correct decimal places, then RELABS should be set to 'A' on entry, whereas if the error requirement is in terms of the number of correct significant digits, then RELABS should be set to 'R'. If the user prefers a mixed error test, then RELABS should be set to 'M', otherwise if the user has no preference, RELABS should be set to the default 'D'. Note that in this case 'D' is taken to be 'M'. Constraint: RELABS = 'M', 'A', 'R', 'D'.

9: RESULT(M,N) -- DOUBLE PRECISION array
Output
On exit: the computed values of the solution at the points given by OUTPUT.

10: OUTPUT -- SUBROUTINE, supplied by the user.
External Procedure
OUTPUT allows the user to have access to intermediate values of the computed solution at successive points specified by the user. These solution values may be returned to the user via the array RESULT if desired (this is a non-standard feature added for use with the Axiom system). OUTPUT is initially called by D02CJF with XSOL = X (the initial value of x). The user must reset XSOL to the next point where OUTPUT is to be called, and so on at each call to OUTPUT. If, after a call to OUTPUT, the reset point XSOL is beyond XEND, D02CJF will integrate to XEND with no further calls to OUTPUT; if a call to OUTPUT is required at the point XSOL = XEND, then XSOL must be given precisely the value XEND.
Its specification is:

```fortran
SUBROUTINE OUTPUT(XSOL,Y,COUNT,M,N,RESULT)
DOUBLE PRECISION Y(N),RESULT(M,N),XSOL
INTEGER M,N,COUNT

1: XSOL -- DOUBLE PRECISION
   Input/Output
   On entry: the current value of the independent
   variable x. On exit: the next value of x at which
   OUTPUT is to be called.

2: Y(N) -- DOUBLE PRECISION array
   Input
   On entry: the computed solution at the point XSOL.

3: COUNT -- INTEGER
   Input/Output
   On entry: Zero if OUTPUT has not been called before, or
   the previous value of COUNT.
   On exit: A new value of COUNT: this can be used to keep
   track of the number of times OUTPUT has been called.

4: M -- INTEGER
   Input
   On entry: The first dimension of RESULT.

5: N -- INTEGER
   Input
   On entry: The dimension of Y.

6: RESULT(M,N) -- DOUBLE PRECISION array
   Input/Output
   On entry: the previous contents of RESULT.
   On exit: RESULT may be used to return the values of the
   intermediate solutions to the user.

OUTPUT must be declared as EXTERNAL in the (sub)program
from which D02CJF is called. Parameters denoted as
Input must not be changed by this procedure.

11: G -- DOUBLE PRECISION FUNCTION, supplied by the user.
   External Procedure
   G must evaluate the function g(x,y) for specified values x,y
   . It specifies the function g for which the first position x
   where g(x,y)=0 is to be found.

   If the user does not require the root finding option, the
   actual argument G must be the dummy routine D02CJW. (D02CJW
   is included in the NAG Foundation Library and so need not be
   supplied by the user).

   Its specification is:

   DOUBLE PRECISION FUNCTION G(X, Y)
   DOUBLE PRECISION X, Y(n)
```
where \( n \) is the actual value of \( N \) in the call of D02CJF.

1: \( X \) -- DOUBLE PRECISION  
   On entry: the value of the independent variable \( x \).

2: \( Y(*) \) -- DOUBLE PRECISION array  
   On entry: the value of the variable \( y \), for \( i = 1, 2, \ldots, n \).

\( G \) must be declared as EXTERNAL in the (sub)program from which D02CJF is called. Parameters denoted as Input must not be changed by this procedure.

12: \( W(28+21*N) \) -- DOUBLE PRECISION array  
   Workspace

13: \( IFAIL \) -- INTEGER  
   On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
   On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

\[ IFAIL = 1 \]
On entry TOL <= 0.0,  
or \( N <= 0 \),  
or RELABS /= 'M', 'A', 'R' or 'D'.

\[ IFAIL = 2 \]
With the given value of TOL, no further progress can be made across the integration range from the current point \( x = X \). (See Section 8 for a discussion of this error exit.) The components \( Y(1), Y(2), \ldots, Y(N) \) contain the computed values of the solution at the current point \( x = X \). If the user has supplied \( g \), then no point at which \( g(x,y) \) changes sign has been located up to the point \( x = X \).

\[ IFAIL = 3 \]
TOL is too small for D02CJF to take an initial step. X and Y
22.3. NAGD.HT

(1), Y(2), ..., Y(N) retain their initial values.

IFAIL = 4
X SOL has not been reset or XSOL lies behind X in the direction of integration, after the initial call to OUTPUT, if the OUTPUT option was selected.

IFAIL = 5
A value of XSOL returned by OUTPUT has not been reset or lies behind the last value of XSOL in the direction of integration, if the OUTPUT option was selected.

IFAIL = 6
At no point in the range X to XEND did the function g(x,y) change sign, if g was supplied. It is assumed that g(x,y) = 0 has no solution.

IFAIL = 7
A serious error has occurred in an internal call. Check all subroutine calls and array sizes. Seek expert help.

7. Accuracy

The accuracy of the computation of the solution vector Y may be controlled by varying the local error tolerance TOL. In general, a decrease in local error tolerance should lead to an increase in accuracy. Users are advised to choose RELABS = 'M' unless they have a good reason for a different choice.

If the problem is a root-finding one, then the accuracy of the root determined will depend on the properties of g(x,y). The user should try to code G without introducing any unnecessary cancellation errors.

8. Further Comments

If more than one root is required then D02QFF(*) should be used.

If the routine fails with IFAIL = 3, then it can be called again with a larger value of TOL if this has not already been tried. If the accuracy requested is really needed and cannot be obtained with this routine, the system may be very stiff (see below) or so badly scaled that it cannot be solved to the required accuracy.

If the routine fails with IFAIL = 2, it is probable that it has been called with a value of TOL which is so small that a solution cannot be obtained on the range X to XEND. This can happen for well-behaved systems and very small values of TOL. The user should, however, consider whether there is a more fundamental difficulty. For example:
(a) in the region of a singularity (infinite value) of the solution, the routine will usually stop with IFAIL = 2, unless overflow occurs first. Numerical integration cannot be continued through a singularity, and analytic treatment should be considered;

(b) for 'stiff' equations where the solution contains rapidly decaying components, the routine will use very small steps in x (internally to D02CJF) to preserve stability. This will exhibit itself by making the computing time excessively long, or occasionally by an exit with IFAIL = 2. Adams methods are not efficient in such cases, and the user should try D02EJF.

9. Example

We illustrate the solution of four different problems. In each case the differential system (for a projectile) is

\[
\begin{align*}
y' &= \tan(\phi) \\
v' &= \frac{-0.032 \tan(\phi) + 0.02v}{v \cos(\phi)} \\
\phi' &= \frac{-0.032}{2v}
\end{align*}
\]

over an interval \( X = 0.0 \) to \( X_{END} = 10.0 \) starting with values \( y=0.5, \ v=0.5, \text{ and } (\phi)=(\pi)/5 \). We solve each of the following problems with local error tolerances 1.0E-4 and 1.0E-5.

(i) To integrate to \( x=10.0 \) producing output at intervals of 2.0 until a point is encountered where \( y=0.0 \).

(ii) As (i) but with no intermediate output.

(iii) As (i) but with no termination on a root-finding condition.

(iv) As (i) but with no intermediate output and no root-finding termination condition.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
Stiff First-order ODE with variable order and step

D02 -- Ordinary Differential Equations
   D02EJF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

Note for users via the Axiom system: the interface to this routine has been enhanced for use with Axiom and is slightly different to that offered in the standard version of the Foundation Library.

1. Purpose

D02EJF integrates a stiff system of first-order ordinary differential equations over an interval with suitable initial conditions, using a variable-order, variable-step method implementing the Backward Differentiation Formulae (BDF), until a user-specified function, if supplied, of the solution is zero, and returns the solution at points specified by the user, if desired.

2. Specification

```fortran
SUBROUTINE D02EJF (X, XEND, M, N, Y, FCN, PEDERV, TOL,
   1   RELABS, OUTPUT, G, W, IW, RESULT, IFAIL)
   INTEGER M, N, IW, IFAIL
   DOUBLE PRECISION X, XEND, Y(N), TOL, G(W(IW)), RESULT(M,N)
   CHARACTER*1 RELABS
```
CHAPTER 22. NAG LIBRARY ROUTINES

EXTERNAL FCN, PEDERV, OUTPUT, G

3. Description

The routine advances the solution of a system of ordinary
differential equations

\[ y' = f(x, y_1, y_2, ..., y_n), \quad i=1,2,...,n, \]

from \( x = X \) to \( x = X_{\text{END}} \) using a variable-order, variable-step
method implementing the BDF. The system is defined by a
subroutine FCN supplied by the user, which evaluates \( f \) in terms
of \( x \) and \( y_1, y_2, ..., y_n \) (see Section 5). The initial values of
\( y_1, y_2, ..., y_n \) must be given at \( x = X \).

The solution is returned via the user-supplied routine OUTPUT at
points specified by the user, if desired: this solution is obtained by C interpolation on solution values produced by the
method. As the integration proceeds a check can be made on the
user-specified function \( g(x, y) \) to determine an interval where it changes sign. The position of this sign change is then determined
accurately by C interpolation to the solution. It is assumed that \( g(x, y) \) is a continuous function of the variables, so that a solution of \( g(x, y) = 0.0 \) can be determined by searching for a change in sign in \( g(x, y) \). The accuracy of the integration, the
interpolation and, indirectly, of the determination of the
position where \( g(x, y) = 0.0 \), is controlled by the parameters TOL and RELABS. The Jacobian of the system \( y' = f(x, y) \) may be supplied in routine PEDERV, if it is available.

For a description of BDF and their practical implementation see
Hall and Watt [1].

4. References

5. Parameters

1: \( X \) -- DOUBLE PRECISION
   Input/Output
   On entry: the initial value of the independent variable \( x \).
   Constraint: \( X /= X_{\text{END}} \)
   On exit: if \( G \) is supplied by the user,
   \( X \) contains the point where \( g(x, y) = 0.0 \), unless \( g(x, y) /= 0.0 \).
22.3. NAGD.HT

0 anywhere on the range X to XEND, in which case, X will contain XEND. If G is not supplied X contains XEND, unless an error has occurred, when it contains the value of x at the error.

2: XEND -- DOUBLE PRECISION
   On entry: the final value of the independent variable. If XEND < X, integration proceeds in the negative direction. Constraint: XEND /= X.

3: M -- INTEGER
   On entry: the first dimension of the array RESULT. This will usually be equal to the number of points at which the solution is required. Constraint: M > 0.

4: N -- INTEGER

5: Y(N) -- DOUBLE PRECISION array
   On entry: the initial values of the solution y, y, ..., y
            1 2 n
   at x = X. On exit: the computed values of the solution at the final point x = X.

6: FCN -- SUBROUTINE, supplied by the user.
   External Procedure
   FCN must evaluate the functions f (i.e., the derivatives
   y') for given values of their arguments x, y, y, ..., y.
   1 2 n
   Its specification is:

   SUBROUTINE FCN (X, Y, F)
       DOUBLE PRECISION X, Y(n), F(n)
   where n is the actual value of N in the call of D02EJF.

1: X -- DOUBLE PRECISION
   On entry: the value of the independent variable x.

2: Y(*) -- DOUBLE PRECISION array
   On entry: the value of the variable y, for
             i = 1, 2, ..., n.

3: F(*) -- DOUBLE PRECISION array
   On exit: the value of f, for i = 1, 2, ..., n.
FCN must be declared as EXTERNAL in the (sub)program from which D02EJF is called. Parameters denoted as Input must not be changed by this procedure.

7: PEDERV -- SUBROUTINE, supplied by the user.

External Procedure

PEDERV must evaluate the Jacobian of the system (that is, the partial derivatives \( \frac{df}{dy} \)) for given values of the variables \( x, y, \ldots, y \).

1: \( X \) -- DOUBLE PRECISION Input
   On entry: the value of the independent variable \( x \).

2: \( Y(*) \) -- DOUBLE PRECISION array Input
   On entry: the value of the variable \( y_i \), for \( i=1,2,\ldots,n \).

3: \( PW(n,*) \) -- DOUBLE PRECISION array Output
   On exit: the value of \( \frac{df}{dy} \), for \( i,j=1,2,\ldots,n \).

If the user does not wish to supply the Jacobian, the actual argument PEDERV must be the dummy routine D02EJY. (D02EJY is included in the NAG Foundation Library and so need not be supplied by the user. The name may be implementation dependent: see the User’s Note for your implementation for details).

PEDERV must be declared as EXTERNAL in the (sub)program from which D02EJF is called. Parameters denoted as Input must not be changed by this procedure.

8: TOL -- DOUBLE PRECISION Input/Output
   On entry: TOL must be set to a positive tolerance for controlling the error in the integration. Hence TOL affects the determination of the position where \( g(x,y) = 0.0 \), if \( G \) is supplied.
D02EJF has been designed so that, for most problems, a reduction in TOL leads to an approximately proportional reduction in the error in the solution. However, the actual relation between TOL and the accuracy achieved cannot be guaranteed. The user is strongly recommended to call D02EJF with more than one value for TOL and to compare the results obtained to estimate their accuracy. In the absence of any prior knowledge, the user might compare the results obtained by calling D02EJF with TOL=10 and TOL=10 if p correct decimal digits are required in the solution. Constraint: TOL > 0.0. On exit: normally unchanged. However if the range X to XEND is so short that a small change in TOL is unlikely to make any change in the computed solution, then, on return, TOL has its sign changed.

9: RELABS -- CHARACTER*1  
Input
On entry: the type of error control. At each step in the numerical solution an estimate of the local error, EST, is made. For the current step to be accepted the following condition must be satisfied:

\[ \frac{|y_i|}{|y_i|} > \frac{1}{(\text{TOL} + \text{TOL})} \]

where (tau) and (tau) are defined by

\[ \begin{align*}
    \text{RELABS} & = 'M' & \text{TOL} & \text{TOL} \\
    'A' & 0.0 & \text{TOL} \\
    'R' & \text{TOL} & \text{(epsilon)} \\
    'D' & \text{TOL} & \text{(epsilon)} \\
\end{align*} \]

where (epsilon) is a small machine-dependent number and e_i is an estimate of the local error at y_i, computed internally. If the appropriate condition is not satisfied, the step size is reduced and the solution is recomputed on the current step. If the user wishes to measure the error in the computed solution in terms of the number of correct decimal places, then RELABS should be set to 'A' on entry, whereas if the error requirement is in terms of the number
of correct significant digits, then RELABS should be set to 'R'. If the user prefers a mixed error test, then RELABS should be set to 'M', otherwise if the user has no preference, RELABS should be set to the default 'D'. Note that in this case 'D' is taken to be 'R'. Constraint: RELABS = 'A', 'M', 'R' or 'D'.

10: OUTPUT -- SUBROUTINE, supplied by the user.

External Procedure

OUTPUT allows the user to have access to intermediate values of the computed solution at successive points specified by the user. These solution values may be returned to the user via the array RESULT if desired (this is a non-standard feature added for use with the Axiom system). OUTPUT is initially called by D02EJF with XSOL = X (the initial value of x). The user must reset XSOL to the next point where OUTPUT is to be called, and so on at each call to OUTPUT. If, after a call to OUTPUT, the reset point XSOL is beyond XEND, D02EJF will integrate to XEND with no further calls to OUTPUT; if a call to OUTPUT is required at the point XSOL = XEND, then XSOL must be given precisely the value XEND.

Its specification is:

```
SUBROUTINE OUTPUT(XSOL,Y,COUNT,M,N,RESULT)
DOUBLE PRECISION Y(N),RESULT(M,N),XSOL
INTEGER M,N,COUNT

1: XSOL -- DOUBLE PRECISION
Input/Output
On entry: the current value of the independent variable x. On exit: the next value of x at which OUTPUT is to be called.

2: Y(N) -- DOUBLE PRECISION array
Input
On entry: the computed solution at the point XSOL.

3: COUNT -- INTEGER
Input/Output
On entry: Zero if OUTPUT has not been called before, or the previous value of COUNT.
On exit: A new value of COUNT: this can be used to keep track of the number of times OUTPUT has been called.

4: M -- INTEGER
Input
On entry: The first dimension of RESULT.

5: N -- INTEGER
Input
On entry: The dimension of Y.

6: RESULT(M,N) -- DOUBLE PRECISION array
Input/Output
On entry: the previous contents of RESULT.
```
On exit: RESULT may be used to return the values of the intermediate solutions to the user.

OUTPUT must be declared as EXTERNAL in the (sub)program from which D02EJF is called. Parameters denoted as Input must not be changed by this procedure.

11: G -- DOUBLE PRECISION FUNCTION, supplied by the user.

External Procedure

G must evaluate the function \( g(x,y) \) for specified values \( x,y \). It specifies the function \( g \) for which the first position \( x \) where \( g(x,y) = 0 \) is to be found.

Its specification is:

```plaintext
DOUBLE PRECISION FUNCTION G (X, Y)
DOUBLE PRECISION X, Y(n)
where n is the actual value of N in the call of D02EJF.
```

1: X -- DOUBLE PRECISION
   On entry: the value of the independent variable \( x \).

2: Y(*) -- DOUBLE PRECISION array
   On entry: the value of the variable \( y \), for \( i = 1, 2, \ldots, n \).

If the user does not require the root finding option, the actual argument G must be the dummy routine D02EJW. (D02EJW is included in the NAG Foundation Library and so need not be supplied by the user).

G must be declared as EXTERNAL in the (sub)program from which D02EJF is called. Parameters denoted as Input must not be changed by this procedure.

12: W(IW) -- DOUBLE PRECISION array
    Workspace

13: IW -- INTEGER
    Input
    On entry: the dimension of the array W as declared in the (sub)program from which D02EJF is called.
    Constraint: \( \text{IW} \geq (12+N)*N+50 \).

14: RESULT(M,N) -- DOUBLE PRECISION array
    Output
    On exit: the computed values of the solution at the points given by OUTPUT.

15: IFAIL -- INTEGER
    Input/Output
    On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1
On entry TOL <= 0.0,

or X = XEND,

or N <= 0,

or RELABS /= 'M', 'A', 'R', 'D'.

or IW<(12+N)*N+50.

IFAIL= 2
With the given value of TOL, no further progress can be made across the integration range from the current point x = X. (See Section 5 for a discussion of this error test.) The components Y(1),Y(2),...,Y(n) contain the computed values of the solution at the current point x = X. If the user has supplied G, then no point at which g(x,y) changes sign has been located up to the point x = X.

IFAIL= 3
TOL is too small for D02EJF to take an initial step. X and Y(1),Y(2),...,Y(n) retain their initial values.

IFAIL= 4
XSOL lies behind X in the direction of integration, after the initial call to OUTPUT, if the OUTPUT option was selected.

IFAIL= 5
A value of XSOL returned by OUTPUT lies behind the last value of XSOL in the direction of integration, if the OUTPUT option was selected.

IFAIL= 6
At no point in the range X to XEND did the function g(x,y) change sign, if G was supplied. It is assumed that g(x,y) = 0 has no solution.
IFAIL= 7
A serious error has occurred in an internal call to
C05AZF(*). Check all subroutine calls and array dimensions.
Seek expert help.

IFAIL= 8
A serious error has occurred in an internal call to
D02XKF(*). Check all subroutine calls and array dimensions.
Seek expert help.

IFAIL= 9
A serious error has occurred in an internal call to
D02NMF(*). Check all subroutine calls and array dimensions.
Seek expert help.

7. Accuracy

The accuracy of the computation of the solution vector $Y$ may be
controlled by varying the local error tolerance $TOL$. In general,
a decrease in local error tolerance should lead to an increase in
accuracy. Users are advised to choose RELABS = 'R' unless they
have a good reason for a different choice. It is particularly
appropriate if the solution decays.

If the problem is a root-finding one, then the accuracy of the
root determined will depend strongly on $---$ and $----$, for
$ddx$ $ddy$ $i$
i=1,2,...,n. Large values for these quantities may imply large
errors in the root.

8. Further Comments

If more than one root is required, then to determine the second
and later roots D02EJF may be called again starting a short
distance past the previously determined roots. Alternatively the
user may construct his own root finding code using D02QDF(*) (or
the routines of the subchapter D02M-D02N), D02XKF(*) and
C05AZF(*).

If it is easy to code, the user should supply the routine PEDERV.
However, it is important to be aware that if PEDERV is coded
incorrectly, a very inefficient integration may result and
possibly even a failure to complete the integration (IFAIL = 2).

9. Example

We illustrate the solution of five different problems. In each
case the differential system is the well-known stiff Robertson
problem.

\[
\begin{align*}
4 & \quad a' = -0.04a - 10bc \\
4 & \quad b' = 0.04a - 10bc - 3 \times 10^2 b \\
7 & \quad c' = 3 \times 10^2 b
\end{align*}
\]

with initial conditions \(a=1.0\), \(b=c=0.0\) at \(x=0.0\). We solve each of the following problems with local error tolerances 1.0E-3 and 1.0E-4.

(i) To integrate to \(x=10.0\) producing output at intervals of 2.0 until a point is encountered where \(a=0.9\). The Jacobian is calculated numerically.

(ii) As (i) but with the Jacobian calculated analytically.

(iii) As (i) but with no intermediate output.

(iv) As (i) but with no termination on a root-finding condition.

(v) Integrating the equations as in (i) but with no intermediate output and no root-finding termination condition.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
D02 -- Ordinary Differential Equations
D02GAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

D02GAF solves the two-point boundary-value problem with assigned boundary values for a system of ordinary differential equations, using a deferred correction technique and a Newton iteration.

2. Specification

```fortran
SUBROUTINE D02GAF (U, V, N, A, B, TOL, FCN, MNP, X, Y, NP, W, LW, IW, LIW, IFAIL)
INTEGER N, MNP, NP, LW, IW(LIW), LIW, IFAIL
DOUBLE PRECISION U(N,2), V(N,2), A, B, TOL, X(MNP), Y(N,MNP), W(LW)
EXTERNAL FCN
```

3. Description

D02GAF solves a two-point boundary-value problem for a system of n differential equations in the interval \([a,b]\). The system is written in the form

\[ y' = f(x, y_1, y_2, \ldots, y_n), \quad i=1,2,\ldots,n \]  

and the derivatives are evaluated by a subroutine FCN supplied by the user. Initially, n boundary values of the variables \(y_i\) must be specified (assigned), some at \(a\) and some at \(b\). The user also supplies estimates of the remaining n boundary values and all the boundary values are used in constructing an initial approximation to the solution. This approximate solution is corrected by a finite-difference technique with deferred correction allied with a Newton iteration to solve the finite-difference equations. The technique used is described fully in Pereyra [1]. The Newton iteration requires a Jacobian matrix

\[ \frac{\partial f}{\partial y_j} \]  

and this is calculated.
by numerical differentiation using an algorithm described in Curtis et al [2].

The user supplies an absolute error tolerance and may also supply an initial mesh for the construction of the finite-difference equations (alternatively a default mesh is used). The algorithm constructs a solution on a mesh defined by adding points to the initial mesh. This solution is chosen so that the error is everywhere less than the user’s tolerance and so that the error is approximately equidistributed on the final mesh. The solution is returned on this final mesh.

If the solution is required at a few specific points then these should be included in the initial mesh. If on the other hand the solution is required at several specific points then the user should use the interpolation routines provided in Chapter E01 if these points do not themselves form a convenient mesh.

4. References

5. Parameters

1: \( U(N,2) \) -- DOUBLE PRECISION array \hspace{1cm} Input
On entry: \( U(i,1) \) must be set to the known (assigned) or estimated values of \( y \) at \( a \) and \( U(i,2) \) must be set to the known or estimated values of \( y \) at \( b \), for \( i=1,2,...,n \).

2: \( V(N,2) \) -- DOUBLE PRECISION array \hspace{1cm} Input
On entry: \( V(i,j) \) must be set to 0.0 if \( U(i,j) \) is a known (assigned) value and to 1.0 if \( U(i,j) \) is an estimated value, \( i=1,2,...,n; j=1,2 \). Constraint: precisely \( N \) of the \( V(i,j) \) must be set to 0.0, i.e., precisely \( N \) of the \( U(i,j) \) must be known values, and these must not be all at \( a \) or all at \( b \).

3: \( N \) -- INTEGER \hspace{1cm} Input
On entry: the number of equations. Constraint: \( N \geq 2 \).
4: A -- DOUBLE PRECISION
   On entry: the left-hand boundary point, a.

5: B -- DOUBLE PRECISION
   On entry: the right-hand boundary point, b. Constraint: B > A.

6: TOL -- DOUBLE PRECISION
   On entry: a positive absolute error tolerance. If
   \[ a = x_1 < x_2 < \ldots < x_n = b \]
   is the final mesh, \( z(x_j) \) is the \( j \)-th component of the
   \( y_i \)
   approximate solution at \( x_j \), and \( y(x) \) is the \( j \)-th component
   \( y_i \)
   of the true solution of equation (1) (see Section 3) and the
   boundary conditions, then, except in extreme cases, it is
   expected that
   \[ |z(x_j) - y(x_j)| \leq TOL, \quad i = 1,2,\ldots, NP; j = 1,2,\ldots,n \]  \( 2 \)
   Constraint: TOL > 0.0.

7: FCN -- SUBROUTINE, supplied by the user.
   External Procedure
   FCN must evaluate the functions \( f_i \) (i.e., the derivatives
   \( y_i' \)) at the general point \( x_i \).
   Its specification is:

   \[
   \text{SUBROUTINE FCN}(X, Y, F) \\
   \text{DOUBLE PRECISION X, Y(n), F(n)}
   \]
   where \( n \) is the actual value of \( N \) in the call of D02GAF.

   1: X -- DOUBLE PRECISION
      On entry: the value of the argument \( x \).

   2: Y(*) -- DOUBLE PRECISION array
      On entry: the value of the argument \( y_i \), for \( i = 1,2,\ldots,n \).

   3: F(*) -- DOUBLE PRECISION array
      On exit: the values of \( f_i \), for \( i = 1,2,\ldots,n \).
      FCN must be declared as EXTERNAL in the (sub)program
      from which D02GAF is called. Parameters denoted as
      Input must not be changed by this procedure.
8: MNP -- INTEGER Input
   On entry: the maximum permitted number of mesh points.
   Constraint: MNP >= 32.

9: X(MNP) -- DOUBLE PRECISION array Input/Output
   On entry: if NP >= 4 (see NP below), the first NP elements
   must define an initial mesh. Otherwise the elements of X
   need not be set. Constraint:
   \[ A = X(1) < X(2) < \ldots < X(NP) = B \] for NP=4
   On exit: X(1),X(2),...,X(NP) define the final mesh (with
   the returned value of NP) satisfying the relation (3).

10: Y(N,MNP) -- DOUBLE PRECISION array Output
    On exit: the approximate solution \( z(x) \) satisfying (2), on
    \[ Y(j,i) = z(x) , \ i=1,2,...,NP; j=1,2,...,n, \]
    where NP is the number of points in the final mesh.
    The remaining columns of Y are not used.

11: NP -- INTEGER Input/Output
    On entry: determines whether a default or user-supplied
    mesh is used. If NP = 0, a default value of 4 for NP and a
    corresponding equispaced mesh X(1),X(2),...,X(NP) are used.
    If NP >= 4, then the user must define an initial mesh using
    the array X as described. Constraint: NP = 0 or 4 <= NP <=
    MNP. On exit: the number of points in the final (returned)
    mesh.

12: W(LW) -- DOUBLE PRECISION array Workspace

13: LW -- INTEGER Input
    On entry: the length of the array W as declared in the
    calling (sub)program. Constraint: \( LW \geq MNP*(3N+6N+2)+4N+4N + 4N \)

14: IW(LIW) -- INTEGER array Workspace

15: LIW -- INTEGER Input
    On entry: the length of the array IW as declared in the
    calling (sub)program. Constraint: \( LIW \geq MNP*(2N+1)+N+4N+2. \)

16: IFAIL -- INTEGER Input/Output
    For this routine, the normal use of IFAIL is extended to
    control the printing of error and warning messages as well
    as specifying hard or soft failure (see the Essential
    Introduction).
Before entry, IFAIL must be set to a value with the decimal expansion $c b a$, where each of the decimal digits $c$, $b$ and $a$ must have a value of 0 or 1.

$a = 0$ specifies hard failure, otherwise soft failure;

$b = 0$ suppresses error messages, otherwise error messages will be printed (see Section 6);

$c = 0$ suppresses warning messages, otherwise warning messages will be printed (see Section 6).

The recommended value for inexperienced users is 110 (i.e., hard failure with all messages printed).

Unless the routine detects an error (see Section 6), IFAIL contains 0 on exit.

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1
One or more of the parameters $N$, $TOL$, $NP$, $MNP$, $LW$ or $LIW$ has been incorrectly set, or $B \leq A$, or the condition (3) on $X$ is not satisfied, or the number of known boundary values (specified by $V$) is not $N$.

IFAIL= 2
The Newton iteration has failed to converge. This could be due to there being too few points in the initial mesh or to the initial approximate solution being too inaccurate. If this latter reason is suspected the user should use subroutine D02RAF instead. If the warning 'Jacobian matrix is singular' is printed this could be due to specifying zero estimated boundary values and these should be varied. This warning could also be printed in the unlikely event of the Jacobian matrix being calculated inaccurately. If the user cannot make changes to prevent the warning then subroutine D02RAF should be used.

IFAIL= 3
The Newton iteration has reached round-off level. It could be, however, that the answer returned is satisfactory. This error might occur if too much accuracy is requested.

IFAIL= 4
A finer mesh is required for the accuracy requested; that is
MNP is not large enough.

IFAIL = 5
A serious error has occurred in a call to D02GAF. Check all array subscripts and subroutine parameter lists in calls to D02GAF. Seek expert help.

7. Accuracy
The solution returned by the routine will be accurate to the user's tolerance as defined by the relation (2) except in extreme circumstances. If too many points are specified in the initial mesh, the solution may be more accurate than requested and the error may not be approximately equidistributed.

8. Further Comments
The time taken by the routine depends on the difficulty of the problem, the number of mesh points used (and the number of different meshes used), the number of Newton iterations and the number of deferred corrections.

The user is strongly recommended to set IFAIL to obtain self-explanatory error messages, and also monitoring information about the course of the computation. The user may select the channel numbers on which this output is to appear by calls of X04AAF (for error messages) or X04ABF (for monitoring information) - see Section 9 for an example. Otherwise the default channel numbers will be used, as specified in the implementation document.

A common cause of convergence problems in the Newton iteration is the user specifying too few points in the initial mesh. Although the routine adds points to the mesh to improve accuracy it is unable to do so until the solution on the initial mesh has been calculated in the Newton iteration.

If the user specifies zero known and estimated boundary values, the routine constructs a zero initial approximation and in many cases the Jacobian is singular when evaluated for this approximation, leading to the breakdown of the Newton iteration.

The user may be unable to provide a sufficiently good choice of initial mesh and estimated boundary values, and hence the Newton iteration may never converge. In this case the continuation facility provided in D02RAF is recommended.

In the case where the user wishes to solve a sequence of similar problems, the final mesh from solving one case is strongly recommended as the initial mesh for the next.
9. Example

We solve the differential equation

\[
y'''' = -y'y' - (\beta)(1-y')
\]

with boundary conditions

\[
y(0) = y'(0) = 0,
\]

\[
y'(10) = 1
\]

for (\beta)=0.0 and (\beta)=0.2 to an accuracy specified by TOL=1.0 E-3. We solve first the simpler problem with (\beta)=0.0 using an equispaced mesh of 26 points and then we solve the problem with (\beta)=0.2 using the final mesh from the first problem.

Note the call to X04ABF prior to the call to D02GAF.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
CHAPTER 22. NAG LIBRARY ROUTINES

Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

D02GBF solves a general linear two-point boundary value problem for a system of ordinary differential equations using a deferred correction technique.

2. Specification

```fortran
SUBROUTINE D02GBF (A, B, N, TOL, FCNF, FCNG, C, D, GAM,
  1 MNP, X, Y, NP, W, LW, IW, LIW, IFAIL)
INTEGER N, MNP, NP, LW, IW(LIW), LIW, IFAIL
DOUBLE PRECISION A, B, TOL, C(N,N), D(N,N), GAM(N), X(MNP),
  1 Y(N,MNP), W(LW)
EXTERNAL FCNF, FCNG
```

3. Description

D02GBF solves the linear two-point boundary value problem for a system of \( n \) ordinary differential equations in the interval \([a,b]\). The system is written in the form

\[
y' = F(x)y + g(x)
\]

and the boundary conditions are written in the form

\[
Cy(a) + Dy(b) = (\gamma)
\]

Here \( F(x), C \) and \( D \) are \( n \) by \( n \) matrices, and \( g(x) \) and \( (\gamma) \) are \( n \)-component vectors. The approximate solution to (1) and (2) is found using a finite-difference method with deferred correction. The algorithm is a specialisation of that used in subroutine D02RAF which solves a nonlinear version of (1) and (2). The nonlinear version of the algorithm is described fully in Pereyra [1].

The user supplies an absolute error tolerance and may also supply an initial mesh for the construction of the finite-difference equations (alternatively a default mesh is used). The algorithm constructs a solution on a mesh defined by adding points to the initial mesh. This solution is chosen so that the error is everywhere less than the user’s tolerance and so that the error is approximately equidistributed on the final mesh. The solution is returned on this final mesh.
If the solution is required at a few specific points then these should be included in the initial mesh. If, on the other hand, the solution is required at several specific points, then the user should use the interpolation routines provided in Chapter E01 if these points do not themselves form a convenient mesh.

4. References

5. Parameters

1: A -- DOUBLE PRECISION Input
   On entry: the left-hand boundary point, a.

2: B -- DOUBLE PRECISION Input
   On entry: the right-hand boundary point, b. Constraint: B > A.

3: N -- INTEGER Input
   On entry: the number of equations; that is n is the order of system (1). Constraint: N >= 2.

4: TOL -- DOUBLE PRECISION Input
   On entry: a positive absolute error tolerance. If
   \[ a = x_1 < x_2 \ldots < x_{NP} = b \]
   is the final mesh, \( z(x) \) is the approximate solution from D02GBF and \( y(x) \) is the true solution of equations (1) and (2) then, except in extreme cases, it is expected that
   \[ \|z-y\| \leq TOL \] (3)
   where
   \[ \|u\| = \max_{1 \leq i \leq N} \max_{1 \leq j \leq NP} |u(x_j)| \]
   Constraint: TOL > 0.0.

5: FCNF -- SUBROUTINE, supplied by the user.

External Procedure

FCNF must evaluate the matrix \( F(x) \) in (1) at a general point \( x \).

Its specification is:

```fortran
SUBROUTINE FCN (X, F)
  DOUBLE PRECISION X, F(n,n)
```
where \( n \) is the actual value of \( N \) in the call of D02GBF.

1: \( X -- \text{DOUBLE PRECISION} \) \hspace{2cm} \text{Input}
   On entry: the value of the independent variable \( x \).

2: \( F(n,n) -- \text{DOUBLE PRECISION array} \) \hspace{2cm} \text{Output}
   On exit: the \((i,j)\)th element of the matrix \( F(x) \), for
   \( i,j=1,2,\ldots,n \). (See Section 9 for an example.)

FCN must be declared as EXTERNAL in the (sub)program
from which D02GBF is called. Parameters denoted as
Input must not be changed by this procedure.

6: \( FCNG -- \text{SUBROUTINE}, \text{supplied by the user.} \)
   External Procedure

FCNG must evaluate the vector \( g(x) \) in (1) at a general point
\( x \).

Its specification is:

```fortran
SUBROUTINE FCNG (X, G)
  DOUBLE PRECISION X, G(n)
```

where \( n \) is the actual value of \( N \) in the call of D02GBF.

1: \( X -- \text{DOUBLE PRECISION} \) \hspace{2cm} \text{Input}
   On entry: the value of the independent variable \( x \).

2: \( G(*) -- \text{DOUBLE PRECISION array} \) \hspace{2cm} \text{Output}
   On exit: the \( i \)th element of the vector \( g(x) \), for
   \( i=1,2,\ldots,n \). (See Section Section 9 for an example.)

FCNG must be declared as EXTERNAL in the (sub)program
from which D02GBF is called. Parameters denoted as
Input must not be changed by this procedure.

7: \( C(N,N) -- \text{DOUBLE PRECISION array} \) \hspace{2cm} \text{Input/Output}

8: \( D(N,N) -- \text{DOUBLE PRECISION array} \) \hspace{2cm} \text{Input/Output}

9: \( GAM(N) -- \text{DOUBLE PRECISION array} \) \hspace{2cm} \text{Input/Output}
   On entry: the arrays \( C \) and \( D \) must be set to the matrices \( C \)
   and \( D \) in (2). \( GAM \) must be set to the vector (gamma) in (2).
   On exit: the rows of \( C \) and \( D \) and the components of \( GAM \) are
   re-ordered so that the boundary conditions are in the order:
   (i) conditions on \( y(a) \) only;
   (ii) condition involving \( y(a) \) and \( y(b) \); and
   (iii) conditions on \( y(b) \) only.

The routine will be slightly more efficient if the arrays \( C \),
\( D \) and \( GAM \) are ordered in this way before entry, and in this
event they will be unchanged on exit.

Note that the problems (1) and (2) must be of boundary value type, that is neither C nor D may be identically zero. Note also that the rank of the matrix \([C,D]\) must be \(n\) for the problem to be properly posed. Any violation of these conditions will lead to an error exit.

10: MNP -- INTEGER
    On entry: the maximum permitted number of mesh points.
    Constraint: MNP >= 32.

11: X(MNP) -- DOUBLE PRECISION array
    On entry: if NP >= 4 (see NP below), the first NP elements
    must define an initial mesh. Otherwise the elements of x
    need not be set. Constraint:
    \[ A = X(1) < X(2) < \ldots < X(NP) = B, \text{ for } NP > 4. \]
    On exit: X(1),X(2),...,X(NP) define the final mesh (with the
    returned value of NP) satisfying the relation (4).

12: Y(N,MNP) -- DOUBLE PRECISION array
    On exit: the approximate solution \(z(x)\) satisfying (3), on
    the final mesh, that is
    \[ Y(j,i) = z \left( x_i \right), i = 1,2,\ldots,NP; j = 1,2,\ldots,n \]
    where NP is the number of points in the final mesh.
    The remaining columns of \(Y\) are not used.

13: NP -- INTEGER
    On entry: determines whether a default mesh or user-supplied
    mesh is used. If NP = 0, a default value of 4 for NP and a
    corresponding equispaced mesh \(X(1),X(2),\ldots,X(NP)\) are used.
    If NP > 4, then the user must define an initial mesh \(X\) as
    in (4) above. On exit: the number of points in the final
    (returned) mesh.

14: W(LW) -- DOUBLE PRECISION array
    Workspace

15: LW -- INTEGER
    On entry: the length of the array \(W\), Constraint:
    \[ 2 \leq LW \leq MNP \times (3N + 5N + 2) + 3N + 5N. \]

16: IW(LIW) -- INTEGER array
    Workspace

17: LIW -- INTEGER
    On entry: the length of the array \(IW\), Constraint:
    \[ LIW \geq MNP \times (2N + 1) + N. \]
18: IFAIL -- INTEGER  
    Input/Output  
    For this routine, the normal use of IFAIL is extended to control the printing of error and warning messages as well as specifying hard or soft failure (see the Essential Introduction).

    Before entry, IFAIL must be set to a value with the decimal expansion cba, where each of the decimal digits c, b and a must have a value of 0 or 1.
    a=0 specifies hard failure, otherwise soft failure;
    
    b=0 suppresses error messages, otherwise error messages will be printed (see Section 6);
    
    c=0 suppresses warning messages, otherwise warning messages will be printed (see Section 6).

    The recommended value for inexperienced users is 110 (i.e., hard failure with all messages printed).

    Unless the routine detects an error (see Section 6), IFAIL contains 0 on exit.

6. Error Indicators and Warnings

Errors detected by the routine:

For each error, an explanatory error message is output on the current error message unit (as defined by X04AAF), unless suppressed by the value of IFAIL on entry.

IFAIL= 1  
One or more of the parameters N, TOL, NP, MNP, LW or LIW is incorrectly set, B <= A or the condition (4) on X is not satisfied.

IFAIL= 2  
There are three possible reasons for this error exit to be taken:

(i) one of the matrices C or D is identically zero (that is the problem is of initial value and not boundary value type). In this case, IW(1) = 0 on exit;

(ii) a row of C and the corresponding row of D are identically zero (that is the boundary conditions are rank deficient). In this case, on exit IW(1) contains the index of the first such row encountered; and

(iii) more than n of the columns of the n by 2n matrix [C,D ] are identically zero (that is the boundary conditions are rank deficient). In this case, on exit
IW(1) contains minus the number of non-identically zero columns.

IFAIL= 3
The routine has failed to find a solution to the specified accuracy. There are a variety of possible reasons including:
(i) the boundary conditions are rank deficient, which may be indicated by the message that the Jacobian is singular. However this is an unlikely explanation for the error exit as all rank deficient boundary conditions should lead instead to error exits with either IFAIL = 2 or IFAIL = 5; see also (iv) below;
(ii) not enough mesh points are permitted in order to attain the required accuracy. This is indicated by NP = MNP on return from a call to D02GBF. This difficulty may be aggravated by a poor initial choice of mesh points;
(iii) the accuracy requested cannot be attained on the computer being used; and
(iv) an unlikely combination of values of F(x) has led to a singular Jacobian. The error should not persist if more mesh points are allowed.

IFAIL= 4
A serious error has occurred in a call to D02GBF. Check all array subscripts and subroutine parameter lists in calls to D02GBF. Seek expert help.

IFAIL= 5
There are two possible reasons for this error exit which occurs when checking the rank of the boundary conditions by reduction to a row echelon form:
(i) at least one row of the n by 2n matrix [C,D] is a linear combination of the other rows and hence the boundary conditions are rank deficient. The index of the first such row encountered is given by IW(1) on exit; and
(ii) as (i) but the rank deficiency implied by this error exit has only been determined up to a numerical tolerance. Minus the index of the first such row encountered is given by IW(1) on exit.
In case (ii) above there is some doubt as to the rank deficiency of the boundary conditions. However even if the boundary conditions are not rank deficient they are not posed in a suitable form for use with this routine.
For example, if

\[
\begin{pmatrix}
1 & 0 \\
1 & 0 \\
1 & 0 \\
\end{pmatrix}
\begin{pmatrix}
\gamma_1 \\
\gamma_2 \\
\end{pmatrix}
\]

\[
C=(1 \epsilon), \quad D=(1 0), \quad \gamma = ((\gamma_1) \epsilon)
\]

and \(\epsilon\) is small enough, this error exit is likely to be taken. A better form for the boundary conditions in this case would be

\[
\begin{pmatrix}
1 & 1 \\
1 & -1 \\
\end{pmatrix}
\begin{pmatrix}
\gamma_1 \\
\end{pmatrix}
\]

\[
C=(0 1), \quad D=(0 0), \quad \gamma = (\epsilon (\gamma_1 - \gamma_2))
\]

7. Accuracy

The solution returned by the routine will be accurate to the user's tolerance as defined by the relation (3) except in extreme circumstances. If too many points are specified in the initial mesh, the solution may be more accurate than requested and the error may not be approximately equidistributed.

8. Further Comments

The time taken by the routine depends on the difficulty of the problem, the number of mesh points (and meshes) used and the number of deferred corrections.

The user is strongly recommended to set IFAIL to obtain self-explanatory error messages, and also monitoring information about the course of the computation. The user may select the channel numbers on which this output is to appear by calls of X04AAF (for error messages) or X04ABF (for monitoring information) - see Section 9 for an example. Otherwise the default channel numbers will be used, as specified in the implementation document.

In the case where the user wishes to solve a sequence of similar problems, the use of the final mesh from one case is strongly recommended as the initial mesh for the next.

9. Example

We solve the problem (written as a first order system)

\[
(\epsilon)y''+y'=0
\]

with boundary conditions

\[
y(0)=0, \quad y(1)=1
\]
for the cases (epsilon)=10 and (epsilon)=10 using the default initial mesh in the first case, and the final mesh of the first case as initial mesh for the second (more difficult) case. We give the solution and the error at each mesh point to illustrate the accuracy of the method given the accuracy request TOL=1.0E-3.

Note the call to X04ABF prior to the call to D02GBF.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
made for discontinuities in the coefficient functions or their
derivatives.

2. Specification

SUBROUTINE D02KEF (XPOINT, M, MATCH, COEFFN, BDYVAL, K,
          TOL, ELAM, DELAM, HMAX, MAXIT, MAXFUN,
          MONIT, REPORT, IFAIL)

     INTEGER M, MATCH, K, MAXIT, MAXFUN, IFAIL
     DOUBLE PRECISION XPOINT(M), TOL, ELAM, DELAM, HMAX(2,M)
     EXTERNAL COEFFN, BDYVAL, MONIT, REPORT

3. Description

D02KEF has essentially the same purpose as D02KDF(*) with minor
modifications to enable values of the eigenfunction to be
obtained after convergence to the eigenvalue has been achieved.

It first finds a specified eigenvalue (\lambda) of a Sturm-
Liouville system defined by a self-adjoint differential equation
of the second-order

\[(p(x)y')' + q(x;\lambda)y = 0, \quad a < x < b\]

together with the appropriate boundary conditions at the two
(finite or infinite) end-points a and b. The functions p and q,
which are real-valued, must be defined by a subroutine COEFFN.
The boundary conditions must be defined by a subroutine BDYVAL,
and, in the case of a singularity at a or b, take the form of an
asymptotic formula for the solution near the relevant end-point.

When the final estimate (\lambda) = (\lambda) of the eigenvalue has
been found, the routine integrates the differential equation once
more with that value of (\lambda), and with initial conditions
chosen so that the integral

\[
\frac{1}{2} \int_a^b \frac{dq}{d\lambda} \left(\frac{\int_a^b \left| y(x) \right|^2 q(x;\lambda) dx}{\int_a^b \left| y(x) \right|^2 (\lambda) dx}\right) dx
\]

is approximately one. When q(x;\lambda) is of the form
(\lambda)w(x)+q(x), which is the most common case, S represents
the square of the norm of y induced by the inner product

\[
\frac{1}{2} \int_a^b \left| y(x) \right|^2 (\lambda) dx
\]
\[ \langle f, g \rangle = \int_a^b f(x)g(x)w(x)\,dx, \]

with respect to which the eigenfunctions are mutually orthogonal. This normalisation of \( y \) is only approximate, but experience shows that \( S \) generally differs from unity by only one or two per cent.

During this final integration the REPORT routine supplied by the user is called at each integration mesh point \( x \). Sufficient information is returned to permit the user to compute \( y(x) \) and \( y'(x) \) for printing or plotting. For reasons described in Section 8.2, D02KEF passes across to REPORT, not \( y \) and \( y' \), but the Pruefer variables \( (\beta) \), \( (\phi) \) and \( (\rho) \) on which the numerical method is based. Their relationship to \( y \) and \( y' \) is given by the equations

\[
\begin{align*}
\rho(x)y' &= \sqrt{\beta} \exp\left( -\frac{\phi}{2}\right) \cos\left( -\frac{\rho}{2}\right); \\
1 &= \sqrt{\beta} \exp\left( -\frac{\phi}{2}\right) \sin\left( -\frac{\rho}{2}\right). \\
\end{align*}
\]

For the theoretical basis of the numerical method to be valid, the following conditions should hold on the coefficient functions:

(a) \( p(x) \) must be non-zero and of one sign throughout the interval \((a,b)\); and,

\[
\frac{dd}{d\lambda} q
\]

(b) \( \frac{dd}{d\lambda} \) must be of one sign throughout \((a,b)\) for all relevant values of \( \lambda \), and must not be identically zero as \( x \) varies, for any \( \lambda \).

Points of discontinuity in the functions \( p \) and \( q \) or their derivatives are allowed, and should be included as 'break-points' in the array XPOINT.

A good account of the theory of Sturm-Liouville systems, with some description of Pruefer transformations, is given in Birkhoff and Rota [4], Chapter X. An introduction for the user of Pruefer transformations for the numerical solution of eigenvalue problems arising from physics and chemistry is Bailey [2].
The scaled Pruefer method is fairly recent, and is described in a short note by Pryce [6] and in some detail in the technical report [5].

4. References

5. Parameters

1: XPOINT(M) -- DOUBLE PRECISION array
   Input
   On entry: the points where the boundary conditions computed by BDYVAL are to be imposed, and also any break-points, i.e., XPOINT(1) to XPOINT(m) must contain values x_1, ..., x_m such that
   \[ x_1 \leq x_2 < x_3 < ... < x_{m-1} \leq x_m \]
   with the following meanings:
   (a) x_1 and x_m are the left and right end-points, a and b, of the domain of definition of the Sturm-Liouville system if these are finite. If either a or b is infinite, the corresponding value x_1 or x_m may be a
   \[ 1 \leq x_1 \leq m \]
   more-or-less arbitrarily 'large' number of appropriate sign.
   (b) x_2 and x_{m-1} are the Boundary Matching Points (BMP's), that is the points at which the left and right
boundary conditions computed in BDYVAL are imposed.

If the left-hand end-point is a regular point then the
user should set \( x = x_1 \) (say), while if it is a singular
point the user must set \( x > x_1 \). Similarly \( x = x_m \)
if the right-hand end-point is regular, and \( x < x_m \) if
it is singular.

(c) The remaining \( m-4 \) points \( x_3, \ldots, x_{m-1} \), if any, define
‘break-points’ which divide the interval \( [x_2, x_m] \)
into \( m-3 \) sub-intervals

\[
i = [x_1, x_2], \ldots, i = [x_{m-3}, x_{m-2}], \ldots, i = [x_{m-3}, x_{m-2}, x_{m-1}]
\]

Numerical integration of the differential equation is
stopped and restarted at each break-point. In simple
cases no break-points are needed. However if \( p(x) \) or
\( q(x; (\lambda)) \) are given by different formulae in
different parts of the range, then integration is more
efficient if the range is broken up by break-points in
the appropriate way. Similarly points where any jumps
occur in \( p(x) \) or \( q(x; (\lambda)) \), or in their
derivatives up to the fifth order, should appear as
break-points.

Constraint: \( x_1 \leq x_2 < \ldots < x_{m-1} \leq x_m \).

2: M -- INTEGER
   Input
   On entry: the number of points in the array XPOINT.
   Constraint: \( M \geq 4 \).

3: MATCH -- INTEGER
   Input/Output
   On entry: MATCH must be set to the index of the ‘break-point’
to be used as the matching point (see Section 3). If
MATCH is set to a value outside the range \( [2, m-1] \) then a
default value is taken, corresponding to the break-point
nearest the centre of the interval \( [XPOINT(2), XPOINT(m-1)] \).
   On exit: the index of the break-point actually used as the
   matching point.

4: COEFFN -- SUBROUTINE, supplied by the user.
   External Procedure
   COEFFN must compute the values of the coefficient functions
   \( p(x) \) and \( q(x; (\lambda)) \) for given values of \( x \) and \( (\lambda) \).
   Section 3 states conditions which \( p \) and \( q \) must satisfy.

   Its specification is:
SUBROUTINE COEFFN (P, Q, DQDL, X, ELAM, JINT)
DOUBLE PRECISION P, Q, DQDL, X, ELAM
INTEGER JINT

1: P -- DOUBLE PRECISION  Output
On exit: the value of p(x) for the current value of x.

2: Q -- DOUBLE PRECISION  Output
On exit: the value of q(x;(lambda)) for the current value of x and the current trial value of (lambda).

3: DQDL -- DOUBLE PRECISION  Output
On exit: the value of \( \frac{\text{ddq}}{\text{dd}(\lambda)} \) for the current value of x and the current trial value of (lambda). However DQDL is only used in error estimation and an approximation (say to within 20%) will suffice.

4: X -- DOUBLE PRECISION  Input
On entry: the current value of x.

5: ELAM -- DOUBLE PRECISION  Input
On entry: the current trial value of the eigenvalue parameter (lambda).

6: JINT -- INTEGER  Input
On entry: the index j of the sub-interval i (see specification of XPOINT) in which x lies.

See Section 8.4 and Section 9 for examples.

COEFFN must be declared as EXTERNAL in the (sub)program from which D02KEF is called. Parameters denoted as Input must not be changed by this procedure.

5: BDYVAL -- SUBROUTINE, supplied by the user.

External Procedure

BDYVAL must define the boundary conditions. For each end-point, BDYVAL must return (in YL or YR) values of y(x) and p(x)y′(x) which are consistent with the boundary conditions at the end-points; only the ratio of the values matters. Here x is a given point (XL or XR) equal to, or close to, the end-point.

For a regular end-point (a, say), x=a; and a boundary condition of the form

\[ c_1 y(a) + c_2 y'(a) = 0 \]
can be handled by returning constant values in $Y_L$, e.g.
$Y_L(1) = c$ and $Y_L(2) = -c$ if $p(a)$.

For a singular end-point however, $Y_L(1)$ and $Y_L(2)$ will in general be functions of $X_L$ and $E_{LAM}$, and $Y_R(1)$ and $Y_R(2)$ functions of $X_R$ and $E_{LAM}$, usually derived analytically from a power-series or asymptotic expansion. Examples are given in Section 8.5 Section 9.

Its specification is:

```fortran
SUBROUTINE BDYVAL (XL, XR, ELAM, YL, YR))
DOUBLE PRECISION XL, XR, ELAM, YL(3), YR(3)

1: XL -- DOUBLE PRECISION Input
On entry: if $a$ is a regular end-point of the system (so that $a = x_1 = x_2$), then XL contains $a$. If $a$ is a singular point (so that $a <= x_1 < x_2$), then XL contains a point $x_2$ such that $x_1 < x_2 <= x_2$.

2: XR -- DOUBLE PRECISION Input
On entry: if $b$ is a regular end-point of the system (so that $x_1 = x_m = b$), then XR contains $b$. If $b$ is a singular point (so that $x_m < x_1 <= b$), then XR contains a point $x_m$ such that $x_m <= x_1 < x_m$.

3: ELAM -- DOUBLE PRECISION Input
On entry: the current trial value of $(\lambda)$.

4: YL(3) -- DOUBLE PRECISION array Output
On exit: $Y_L(1)$ and $Y_L(2)$ should contain values of $y(x)$ and $p(x)y'(x)$ respectively (not both zero) which are consistent with the boundary condition at the left-hand end-point, given by $x = XL$. $Y_L(3)$ should not be set.

5: YR(3) -- DOUBLE PRECISION array Output
On exit: $Y_R(1)$ and $Y_R(2)$ should contain values of $y(x)$ and $p(x)y'(x)$ respectively (not both zero) which are consistent with the boundary condition at the right-hand end-point, given by $x = XR$. $Y_R(3)$ should not be set.

BDYVAL must be declared as EXTERNAL in the (sub)program...
from which D02KEF is called. Parameters denoted as Input must not be changed by this procedure.

6: K -- INTEGER Input
On entry: the index k of the required eigenvalue when the eigenvalues are ordered
\[ \lambda_0 < \lambda_1 < \lambda_2 < \ldots < \lambda_k \]
Constraint: \( K \geq 0 \).

7: TOL -- DOUBLE PRECISION Input
On entry: the tolerance parameter which determines the accuracy of the computed eigenvalue. The error estimate held in DELAM on exit satisfies the mixed absolute/relative error test
\[ \text{DELAM} \leq TOL \times \max(1.0,|\text{ELAM}|) \]
where ELAM is the final estimate of the eigenvalue. DELAM is usually somewhat smaller than the right-hand side of (*) but not several orders of magnitude smaller. Constraint: \( TOL > 0.0 \).

8: ELAM -- DOUBLE PRECISION Input/Output
On entry: an initial estimate of the eigenvalue \( \lambda \).
On exit: the final computed estimate, whether or not an error occurred.

9: DELAM -- DOUBLE PRECISION Input/Output
On entry: an indication of the scale of the problem in the \( \lambda \)-direction. DELAM holds the initial 'search step' (positive or negative). Its value is not critical but the first two trial evaluations are made at ELAM and ELAM + DELAM, so the routine will work most efficiently if the eigenvalue lies between these values. A reasonable choice (if a closer bound is not known) is half the distance between adjacent eigenvalues in the neighbourhood of the one sought. In practice, there will often be a problem, similar to the one in hand but with known eigenvalues, which will help one to choose initial values for ELAM and DELAM.

If \( \text{DELAM} = 0.0 \) on entry, it is given the default value of \( 0.25 \times \max(1.0,|\text{ELAM}|) \). On exit: with IFAIL = 0, DELAM holds an estimate of the absolute error in the computed eigenvalue, that is \( |\lambda - \text{ELAM}| \approx \text{DELAM} \). (In Section 8.2 we discuss the assumptions under which this is true.) The true error is rarely more than twice, or less than a tenth, of the estimated error.

With IFAIL /= 0, DELAM may hold an estimate of the error, or
its initial value, depending on the value of IFAIL. See Section 6 for further details.

10: HMAX(2,M) -- DOUBLE PRECISION array

On entry: HMAX(1,j) a maximum step size to be used by the differential equation code in the jth sub-interval i (as described in the specification of parameter XPOINT), for j=1,2,...,m-3. If it is zero the routine generates a maximum step size internally.

It is recommended that HMAX(1,j) be set to zero unless the coefficient functions p and q have features (such as a narrow peak) within the jth sub-interval that could be 'missed' if a long step were taken. In such a case HMAX(1,j) should be set to about half the distance over which the feature should be observed. Too small a value will increase the computing time for the routine. See Section 8 for further suggestions.

The rest of the array is used as workspace. On exit: HMAX(1,m-1) and HMAX(1,m) contain the sensitivity coefficients \((\sigma_l, \sigma_r)\), described in Section 8.6. Other entries contain diagnostic output in case of an error (see Section 6).

11: MAXIT -- INTEGER

On entry: a bound on \(n_r\), the number of root-finding iterations allowed, that is the number of trial values of \((\lambda)\) that are used. If MAXIT <= 0, no such bound is assumed. (See also under MAXFUN.) Suggested value: MAXIT = 0. On exit: MAXIT will have been decreased by the number of iterations actually performed, whether or not it was positive on entry.

12: MAXFUN -- INTEGER

On entry: a bound on \(n_f\), the number of calls to COEFFN made in any one root-finding iteration. If MAXFUN <= 0, no such bound is assumed. Suggested value: MAXFUN = 0.

MAXFUN and MAXIT may be used to limit the computational cost of a call to D02KEF, which is roughly proportional to \(n_r \times n_f\).

13: MONIT -- SUBROUTINE, supplied by the user.

MONIT is called by D02KEF at the end of each root-finding...
iteration and allows the user to monitor the course of the computation by printing out the parameters (see Section 8 for an example).
If no monitoring is required, the dummy subroutine D02KAY may be used. (D02KAY is included in the NAG Foundation Library).

Its specification is:

```fortran
SUBROUTINE MONIT (MAXIT, IFLAG, ELAM, FINFO)
INTEGER MAXIT, IFLAG
DOUBLE PRECISION ELAM, FINFO(15)
```

1: MAXIT -- INTEGER  Input
On entry: the current value of the parameter MAXIT of D02KEF; this is decreased by one at each iteration.

2: IFLAG -- INTEGER  Input
On entry: IFLAG describes what phase the computation is in, as follows:
IFLAG < 0
an error occurred in the computation of the 'miss-distance' at this iteration;
an error exit from D02KEF with IFAIL =-IFLAG will follow.

IFLAG = 1
the routine is trying to bracket the eigenvalue-
(lambda).

IFLAG = 2
the routine is converging to the eigenvalue-
(lambda) (having already bracketed it).

3: ELAM -- DOUBLE PRECISION  Input
On entry: the current trial value of (lambda).

4: FINFO(15) -- DOUBLE PRECISION array  Input
On entry: information about the behaviour of the shooting method, and diagnostic information in the case of errors. It should not normally be printed in full if no error has occurred (that is, if IFLAG > 0), though the first few components may be of interest to the user. In case of an error (IFLAG < 0) all the components of FINFO should be printed. The contents of FINFO are as follows:
FINFO(1): the current value of the 'miss-distance' or 'residual' function $f(\lambda)$ on which the shooting method is based. FINFO(1) is set to zero if IFLAG < 0.

FINFO(2): an estimate of the quantity $dd(\lambda)$ defined as follows. Consider the perturbation in the miss-distance $f(\lambda)$ that would result if the local error, in the solution of the differential equation, were always positive and equal to its maximum permitted value. Then $dd(\lambda)$ is the perturbation in $\lambda$ that would have the same effect on $f(\lambda)$. Thus, at the zero of $f(\lambda)$, $|dd(\lambda)|$ is an approximate bound on the perturbation of the zero (that is the eigenvalue) caused by errors in numerical solution. If $dd(\lambda)$ is very large then it is possible that there has been a programming error in COEFFN such that $q$ is independent of $\lambda$. If this is the case, an error exit with IFAIL = 5 should follow. FINFO(2) is set to zero if IFLAG < 0.

FINFO(3): the number of internal iterations, using the same value of $\lambda$ and tighter accuracy tolerances, needed to bring the accuracy (that is the value of $dd(\lambda)$) to an acceptable value. Its value should normally be 1.0, and should almost never exceed 2.0.

FINFO(4): the number of calls to COEFFN at this iteration.

FINFO(5): the number of successful steps taken by the internal differential equation solver at this iteration. A step is successful if it is used to advance the integration (cf. COUT(8) in specification of D02PAF(*)).

FINFO(6): the number of unsuccessful steps used by the internal integrator at this iteration (cf. COUT(9) in specification of D02PAF(*)).

FINFO(7): the number of successful steps at the maximum step size taken by the internal integrator at this iteration (cf. COUT(3) in specification of D02PAF(*)).

FINFO(8): is not used.

FINFO(9) to FINFO(15): set to zero, unless IFLAG < 0 in which case they hold the following values describing the point of failure:

FINFO(9): contains the index of the sub-interval where
failure occurred, in the range 1 to \( m-3 \). In case of an
error in BDYVAL, it is set to 0 or \( m-2 \) depending on
whether the left or right boundary condition caused the
error.

FINFO(10): the value of the independent variable \( x \), the
point at which error occurred. In case of an error in
BDYVAL, it is set to the value of XL or XR as
appropriate (see the specification of BDYVAL).

FINFO(11), FINFO(12), FINFO(13): the current values of
the Pruefer dependent variables \((\beta)\), \((\phi)\) and \((\rho)\)
respectively. These are set to zero in case of an error
in BDYVAL.

FINFO(14): the local-error tolerance being used by the
internal integrator at the point of failure. This is
set to zero in the case of an error in BDYVAL.

FINFO(15): the last integration mesh point. This is set
to zero in the case of an error in BDYVAL.

MONIT must be declared as EXTERNAL in the (sub)program
from which D02KEF is called. Parameters denoted as
Input must not be changed by this procedure.

14: REPORT -- SUBROUTINE, supplied by the user.

External Procedure

This routine provides the means by which the user may
compute the eigenfunction \( y(x) \) and its derivative at each
integration mesh point \( x \). (See Section 8 for an example).

Its specification is:

\[
\text{SUBROUTINE REPORT (X, V, JINT)}
\]
\[
\text{INTEGER JINT}
\]
\[
\text{DOUBLE PRECISION X, V(3)}
\]

1: \( X \) -- DOUBLE PRECISION
On entry: the current value of the independent variable
\( x \). See Section 8.3 for the order in which values of \( x \)
are supplied.

2: \( V(3) \) -- DOUBLE PRECISION array
On entry: \( V(1), V(2), V(3) \) hold the current values of
the Pruefer variables \((\beta), (\phi), (\rho)\)
respectively.

3: \( JINT \) -- INTEGER
On entry: JINT indicates the sub-interval between
break-points in which \( x \) lies exactly as for the routine
COEFFN, except that at the extreme left end-point (when
\( x = XPOINT(2) \)) JINT is set to 0 and at the extreme
right end-point (when \( x = XPOINT(m-1) \)) JINT is set to
\( r \).

REPORT must be declared as EXTERNAL in the (sub)program
from which D02KEF is called. Parameters denoted as
Input must not be changed by this procedure.

15: IFAIL -- INTEGER  Input/Output

On entry: IFAIL must be set to 0, -1 or 1. For users not
familiar with this parameter (described in the Essential
Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see
Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
A parameter error. All parameters (except IFAIL) are left
unchanged. The reason for the error is shown by the value of
HMAX(2,1) as follows:
HMAX(2,1) = 1: M < 4;
HMAX(2,1) = 2: K < 0;
HMAX(2,1) = 3: TOL <= 0.0;
HMAX(2,1) = 4: XPOINT(1) to XPOINT(m) are not in ascending
order.

HMAX(2,2) gives the position i in XPOINT
where this was detected.

IFAIL= 2
At some call to BDYVAL, invalid values were returned, that
is, either YL(1) = YL(2) = 0.0, or YR(1) = YR(2) = 0.0 (a
programming error in BDYVAL). See the last call of MONIT for
details.

This error exit will also occur if \( p(x) \) is zero at the point
where the boundary condition is imposed. Probably BDYVAL was
called with XL equal to a singular end-point a or with XR
equal to a singular end-point b.

IFAIL= 3
At some point between XL and XR the value of \( p(x) \) computed
by COEFFN became zero or changed sign. See the last call of MONIT for details.

IFAIL = 4
MAXIT > 0 on entry, and after MAXIT iterations the eigenvalue had not been found to the required accuracy.

IFAIL = 5
The 'bracketing' phase (with parameter IFLAG of MONIT equal to 1) failed to bracket the eigenvalue within ten iterations. This is caused by an error in formulating the problem (for example, \( q \) is independent of \( \lambda \)), or by very poor initial estimates of ELAM, DELAM.

On exit ELAM and ELAM + DELAM give the end-points of the interval within which no eigenvalue was located by the routine.

IFAIL = 6
MAXFUN > 0 on entry, and the last iteration was terminated because more than MAXFUN calls to COEFFN were used. See the last call of MONIT for details.

IFAIL = 7
To obtain the desired accuracy the local error tolerance was set so small at the start of some sub-interval that the differential equation solver could not choose an initial step size large enough to make significant progress. See the last call of MONIT for diagnostics.

IFAIL = 8
At some point inside a sub-interval the step size in the differential equation solver was reduced to a value too small to make significant progress (for the same reasons as with IFAIL = 7). This could be due to pathological behaviour of \( p(x) \) and \( q(x;\lambda) \) or to an unreasonable accuracy requirement or to the current value of \( \lambda \) making the equations 'stiff'. See the last call of MONIT for details.

IFAIL = 9
TOL is too small for the problem being solved and the machine precision is being used. The final value of ELAM should be a very good approximation to the eigenvalue.

IFAIL = 10
CO5AZF(\*), called by D02KEF, has terminated with the error exit corresponding to a pole of the residual function \( f(\lambda) \). This error exit should not occur, but if it does, try solving the problem again with a smaller value for TOL.
IFAIL= 11
A serious error has occurred in an internal call to D02KDY.
Check all subroutine calls and array dimensions. Seek expert help.

IFAIL= 12
A serious error has occurred in an internal call to C05AZF(*).
Check all subroutine calls and array dimensions. Seek expert help.

HMAX(2,1) holds the failure exit number from the routine where the failure occurred. In the case of a failure in C05AZF(*), HMAX(2,2) holds the value of parameter IND of C05AZF(*).

Note: error exits with IFAIL = 2, 3, 6, 7, 8, 11 are caused by being unable to set up or solve the differential equation at some iteration, and will be immediately preceded by a call of MONIT giving diagnostic information. For other errors, diagnostic information is contained in HMAX(2,j), for j=1,2,...,m, where appropriate.

7. Accuracy
See the discussion in Section 8.2.

8. Further Comments

8.1. Timing
The time taken by the routine depends on the complexity of the coefficient functions, whether they or their derivatives are rapidly changing, the tolerance demanded, and how many iterations are needed to obtain convergence. The amount of work per iteration is roughly doubled when TOL is divided by 16. To make the most economical use of the routine, one should try to obtain good initial values for ELAM and DELAM, and, where appropriate, good asymptotic formulae. The boundary matching points should not be set unnecessarily close to singular points. The extra time needed to compute the eigenfunction is principally the cost of one additional integration once the eigenvalue has been found.

8.2. General Description of the Algorithm
A shooting method, for differential equation problems containing unknown parameters, relies on the construction of a 'miss-distance function', which for given trial values of the parameters measures how far the conditions of the problem are from being met. The problem is then reduced to one of finding the
values of the parameters for which the miss-distance function is zero, that is to a root-finding process. Shooting methods differ mainly in how the miss-distance is defined.

This routine defines a miss-distance $f(\lambda)$ based on the rotation around the origin of the point $P(x) = (p(x)y'(x), y(x))$ in the Phase Plane as the solution proceeds from $a$ to $b$. The boundary-conditions define the ray (i.e., two-sided line through the origin) on which $p(x)$ should start, and the ray on which it should finish. The eigenvalue index $k$ defines the total number of half-turns it should make. Numerical solution is actually done by matching point $x=c$. Then $f(\lambda)$ is taken as the angle between the rays to the two resulting points $P(c)$ and $P(c)$. A relative scaling of the $py'$ and $y$ axes, based on the behaviour of the coefficient functions $p$ and $q$, is used to improve the numerical behaviour.

Please see figure in printed Reference Manual

The resulting function $f(\lambda)$ is monotonic over $-\infty < \lambda < \infty$, increasing if $\frac{df}{d\lambda} > 0$ and decreasing if $\frac{df}{d\lambda} < 0$, with a unique zero at the desired eigenvalue $\lambda$. The routine measures $f(\lambda)$ in units of a half-turn. This means that as $\lambda$ increases, $f(\lambda)$ varies by about 1 as each eigenvalue is passed. (This feature implies that the values of $f(\lambda)$ at successive iterations — especially in the early stages of the iterative process — can be used with suitable extrapolation or interpolation to help the choice of initial estimates for eigenvalues near to the one currently being found.)

The routine actually computes a value for $f(\lambda)$ with errors, arising from the local errors of the differential equation code and from the asymptotic formulae provided by the user if singular points are involved. However, the error estimate output in $\text{DELAM}$ is usually fairly realistic, in that the actual error $|\lambda - \text{ELAM}|$ is within an order of magnitude of $\text{DELAM}$.

We pass the values of $(\beta), (\phi), (\rho)$ across through REPORT rather than converting them to values of $y, y'$ inside $\text{D02KEF}$, for the following reasons. First, there may be cases where auxiliary
quantities can be more accurately computed from the Pruefer variables than from \( y \) and \( y' \). Second, in singular problems on an infinite interval \( y \) and \( y' \) may underflow towards the end of the range, whereas the Pruefer variables remain well-behaved. Third, with high-order eigenvalues (and therefore highly oscillatory eigenfunctions) the eigenfunction may have a complete oscillation (or more than one oscillation) between two mesh points, so that values of \( y \) and \( y' \) at mesh points give a very poor representation of the curve. The probable behaviour of the Pruefer variables in this case is that \( \beta \) and \( \rho \) vary slowly whilst \( \phi \) increases quickly: for all three Pruefer variables linear interpolation between the values at adjacent mesh points is probably sufficiently accurate to yield acceptable intermediate values of \( \beta \), \( \phi \), \( \rho \) (and hence of \( y,y' \)) for graphical purposes.

Similar considerations apply to the exponentially decaying 'tails Here \( \phi \) has approximately constant value whilst \( \rho \) increases rapidly in the direction of integration, though the step length is generally fairly small over such a range.

If the solution is output through REPORT at \( x \)-values which are too widely spaced, the step length can be controlled by choosing NMAX suitably, or, preferably, by reducing TOL. Both these choices will lead to more accurate eigenvalues and eigenfunctions but at some computational cost.

8.3. The Position of the Shooting Matching Point \( c \)

This point is always one of the values \( x \) in array XPOINT. It may be specified using the parameter MATCH. The default value is chosen to be the value of that \( x \), \( 2 \leq i \leq m-1 \), that lies closest to the middle of the interval \( [x_2, x_{m-1}] \). If there is a tie, the rightmost candidate is chosen. In particular if there are no break-points then \( c=x_m \) (=x ) - that is the shooting is from left to right in this case. A break-point may be inserted purely to move \( c \) to an interior point of the interval, even though the form of the equations does not require it. This often speeds up convergence especially with singular problems.

Note that the shooting method used by the code integrates first from the left-hand end \( x \), then from the right-hand end \( x \), to meet at the matching point \( c \) in the middle. This will of course be reflected in printed or graphical output. The diagram shows a possible sequence of nine mesh points (\( \tau \)) through (\( \tau \)) in
the order in which they appear, assuming there are just two sub-
intervals (so m=5).

Figure 1
Please see figure in printed Reference Manual

Since the shooting method usually fails to match up the two 'legs
p(x)y' or both, at the matching point c. The code in fact 'shares
large jump does not imply an inaccurate eigenvalue, but implies
either

(a) a badly chosen matching point: if q(x;(lambda)) has a 'humped'
shape, c should be chosen near the maximum value of
q, especially if q is negative at the ends of the interval.

(b) An inherently ill-conditioned problem, typically one where
another eigenvalue is pathologically close to the one being
sought. In this case it is extremely difficult to obtain an
accurate eigenfunction.

In Section 9 below, we find the 11th eigenvalue and corresponding
eigenfunction of the equation

\[ y'' + ((\lambda) - x - 2/x) y = 0 \quad \text{on } 0 < x < \infty \]

the boundary conditions being that y should remain bounded as x
tends to 0 and x tends to \( \infty \). The coding of this problem is
discussed in detail in Section 8.5.

The choice of matching point c is open. If we choose \( c=30.0 \) as in
the D02KDF(*) example program we find that the exponentially
increasing component of the solution dominates and we get
extremely inaccurate values for the eigenfunction (though the
eigenvalue is determined accurately). The values of the
eigenfunction calculated with \( c=30.0 \) are given schematically in
Figure 2.

Figure 2
Please see figure in printed Reference Manual

If we choose c as the maximum of the hump in q(x;(lambda)) (see
(a) above) we instead obtain the accurate results given in
Figure 3.

Figure 3
8.4. Examples of Coding the COEFFN Routine

Coding COEFFN is straightforward except when break-points are needed. The examples below show:

(a) a simple case,

(b) a case in which discontinuities in the coefficient functions or their derivatives necessitate break-points, and

(c) a case where break-points together with the HMAX parameter are an efficient way to deal with a coefficient function that is well-behaved except over one short interval.

Example A

The modified Bessel equation

\[ x^{2} (x y')' + ((\lambda) - (\nu)/x)y = 0 \]

Assuming the interval of solution does not contain the origin, dividing through by \(x\), we have \(p(x) = x,\)

\[ q(x; (\lambda)) = (\lambda) - (\nu)/x. \]

The code could be

```fortran
SUBROUTINE COEFFN(P, Q, DQDL, X, ELAM, JINT)
   P = X
   Q = ELAM * X + NU * NU / X
   DQDL = X
   RETURN
END
```

where NU (standing for \((\nu)\)) is a real variable that might be defined in a DATA statement, or might be in user-declared COMMON so that its value could be set in the main program.

Example B

The Schroedinger equation

\[ y'' + ((\lambda) + q(x))y = 0 \]

\[
\begin{cases}
\{ 2 \\
\{ x - 10 (|x| <= 4),
\end{cases}
\]
where \( q(x) = \frac{6}{|x|} \) \((|x|>4)\),

over some interval 'approximating to (-\infty,\infty)', say \([-20, 20]\). Here we need break-points at \(\pm 4\), forming three sub-intervals \(i = [-20, -4], i = [-4, 4], i = [4, 20]\). The code could be

```fortran
SUBROUTINE COEFFN(P,Q,DQDL,X,ELAM,JINT)
  IF (JINT.EQ.2) THEN
    Q = ELAM + X*X - 10.0E0
  ELSE
    Q = ELAM + 6.0E0/ABS(X)
  ENDIF
  P = 1.0E0
  DQDL = 1.0E0
RETURN
END
```

The array XPOINT would contain the values \(x, -20.0, -4.0, +4.0, \ldots +20.0, x\) and \(m\) would be 6. The choice of appropriate values for \(x\) and \(x\) depends on the form of the asymptotic formula computed by BDYVAL and the technique is discussed in the next subsection.

**Example C**

\[
y'' + (\lambda)(1 - 2e^{-100x})y = 0, \text{ over } -10 \leq x \leq 10
\]

Here \(q(x; \lambda)\) is nearly constant over the range except for a sharp inverted spike over approximately \(-0.1 \leq x \leq 0.1\). There is a danger that the routine will build up to a large step size and 'step over' the spike without noticing it. By using break-points - say at \(\pm 0.5\) - one can restrict the step size near the spike without impairing the efficiency elsewhere.

The code for COEFFN could be

```fortran
SUBROUTINE COEFFN(P,Q,DQDL,X,ELAM,JINT)
  P = 1.0E0
  DQDL = 1.0E0 - 2.0E0*EXP(-100.0E0*X*X)
  Q = ELAM*DQDL
RETURN
```
XPOINT might contain \(-0.0, -10.0, -0.5, 0.5, 10.0, 10.0\) (assuming 
+- 10 are regular points) and m would be 6. HMAX(1,j), j=1,2,3 
might contain 0.0, 0.1 and 0.0.

8.5. Examples of Boundary Conditions at Singular Points

Quoting from Bailey [2] page 243: 'Usually... the differential 
equation has two essentially different types of solution near a 
singular point, and the boundary condition there merely serves to 
distinguish one kind from the other. This is the case in all the 
standard examples of mathematical physics.'

In most cases the behaviour of the ratio \(p(x)y'/y\) near the point 
is quite different for the two types of solution. Essentially 
what the user provides through his BDYVAL routine is an 
approximation to this ratio, valid as \(x\) tends to the singular 
point (SP).

The user must decide (a) how accurate to make this approximation 
or asymptotic formula, for example how many terms of a series to 
use, and (b) where to place the boundary matching point (BMP) at 
which the numerical solution of the differential equation takes 
over from the asymptotic formula. Taking the BMP closer to the SP 
will generally improve the accuracy of the asymptotic formula, 
but will make the computation more expensive as the Pruefer 
differential equations generally become progressively more ill-
behaved as the SP is approached. The user is strongly recommended 
to experiment with placing the BMFS. In many singular problems 
quite crude asymptotic formulae will do. To help the user avoid 
needlessly accurate formulae, D02KEF outputs two 'sensitivity 
coefficients' \((\sigma)\), \((\sigma)\) which estimate how much the 
\(l\ r\) errors at the BMP's affect the computed eigenvalue. They are 
described in detail below, see Section 8.6.

Example of coding BDYVAL:

The example below illustrates typical situations:

\[
\begin{align*}
  y'' + (\lambda - x - \cdots)y &= 0, \text{ for } 0 < x < \infty \\
  (2) &
\end{align*}
\]

the boundary conditions being that \(y\) should remain bounded as \(x\) 
tends to 0 and \(x\) tends to infinity.
At the end $x=0$ there is one solution that behaves like $x$ and $-1$ another that behaves like $x$. For the first of these solutions $p(x)y'/y$ is asymptotically $2/x$ while for the second it is asymptotically $-1/x$. Thus the desired ratio is specified by setting

\[ YL(1) = x \text{ and } YL(2) = 2.0. \]

At the end $x=\infty$ the equation behaves like Airy's equation shifted through $(\lambda)$, i.e., like $y''-ty=0$ where $t=x-(\lambda)$, so again there are two types of solution. The solution we require behaves as

\[
\left( \frac{2}{3} \right)^{3/2} \frac{4}{\sqrt{t}} \\
\exp(-t) / \sqrt{t}
\]

and the other as

\[
\left( \frac{2}{3} \right)^{3/2} \frac{4}{\sqrt{t}} \\
\exp(+t) / \sqrt{t}
\]

once, the desired solution has $p(x)y'/y \sim \sqrt{t}$ so that we could set

\[ YR(1) = 1.0 \text{ and } YR(2) = -\sqrt{x-(\lambda)}. \]

The complete subroutine might thus be

```
SUBROUTINE BDYVAL(XL,XR,ELAM,YL,YR)
real XL, XR, ELAM, YL(3), YR(3)
YL(1) = XL
YL(2) = 2.0E0
YR(1) = 1.0E0
YR(2) = -SQRT(XR - ELAM)
RETURN
END
```

Clearly for this problem it is essential that any value given by D02KEF to XR is well to the right of the value of ELAM, so that the user must vary the right-hand BMP with the eigenvalue index $k$ function $Ai(x)$, so there is no problem in estimating ELAM.

More accurate asymptotic formulae are easily found - near $x=0$ by the standard Frobenius method, and near $x=\infty$ by using standard
asymptotics for $A_i(x)$, $A_i'(x)$ (see [1], p. 448). For example, by the Frobenius method the solution near $x=0$ has the expansion

$$y = x^{2/3} (c_0 + c_1 x + c_2 x^2 + \ldots)$$

with

$$c_0 = -(\lambda_0), c_1 = 0, c_2 = -\frac{1}{10}, \ldots, c_n = \frac{1}{n(n+3)}$$

This yields

$$5 \frac{p(x)y'}{y} = -(\lambda_0)x^{2/3} + \ldots$$

8.6. The Sensitivity Parameters ($\sigma_l$) and ($\sigma_r$)

The sensitivity parameters ($\sigma_l$), ($\sigma_r$) (held in HMAX(1,m-1) and HMAX(1,m) on output) estimate the effect of errors in the boundary conditions. For sufficiently small errors ($\Delta y$, ($\Delta p y'$ in $y$ and $p y'$ respectively, the relations

$$(\Delta \lambda) = (y.(\Delta p y' - p y').(\Delta y) \quad (\sigma_l)$$

and

$$(\Delta \lambda) = (y.(\Delta p y' - p y').(\Delta y) \quad (\sigma_r)$$

are satisfied where the subscripts $l$, $r$ denote errors committed at left- and right-hand BMP's respectively, and ($\Delta \lambda$) denotes the consequent error in the computed eigenvalue.

8.7. Missed Zeros

This is a pitfall to beware of at a singular point. If the BMP is chosen so far from the SP that a zero of the desired eigenfunction lies in between them, then the routine will fail to number of zeros of its eigenfunction, the result will be that:
(a) The wrong eigenvalue will be computed for the given index \( k \) - in fact some \((\lambda)\) will be found where \( k' \geq 1 \).

\[ k + k' \]

(b) The same index \( k \) can cause convergence to any of several eigenvalues depending on the initial values of ELAM and DELAM.

It is up to the user to take suitable precautions - for instance by varying the position of the BMP's in the light of his knowledge of the asymptotic behaviour of the eigenfunction at different eigenvalues.

9. Example

To find the 11th eigenvalue and eigenfunction of the example of Section 8.5, using the simple asymptotic formulae for the boundary conditions.

Comparison of the results from this example program with the corresponding results from D02KDF(*) example program shows that similar output is produced from the routine MONIT, followed by the eigenfunction values from REPORT, and then a further line of information from MONIT (corresponding to the integration to find the eigenfunction). Final information is printed within the example program exactly as with D02KDF(*).

Note the discrepancy at the matching point \( c(=\sqrt{\lambda}) \), the maximum of \( q(x;\lambda) \), in this case) between the solutions obtained by integrations from left and right end-points.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

Two-point boundary-value ODE equation systems

— nagd.ht —

\begin{verbatim}

\end{page}

— nagd.ht —
D02RAF solves the two-point boundary-value problem with general boundary conditions for a system of ordinary differential equations, using a deferred correction technique and Newton iteration.

2. Specification

SUBROUTINE D02RAF (N, MNP, NP, NUMBEG, NUMMIX, TOL, INIT, 1 X, Y, IY, ABT, FCN, G, IJAC, JACOB, JACOBF, 2 JACOBG, DELEPS, JACEPS, JACGEP, WORK, 3 LWORK, IWORK, LIWORK, IFAIL)

INTEGER N, MNP, NP, NUMBEG, NUMMIX, INIT, IY, 1 IJAC, LWORK, IWORK(LIWORK), LIWORK, IFAIL
DOUBLE PRECISION TOL, X(MNP), Y(IY,MNP), ABT(N), DELEPS, 1 WORK(LWORK)
EXTERNAL FCN, G, JACOB, JACOBG, JACOBF, JACEPS, JACGEP

3. Description

D02RAF solves a two-point boundary-value problem for a system of n ordinary differential equations in the interval (a,b) with b>a. The system is written in the form

\[
y'_i = f(x, y_i, y_{i+1}, \ldots, y_n), \quad i=1,2,\ldots,n
\]  

and the derivatives \( f \) are evaluated by a subroutine FCN supplied by the user. With the differential equations (1) must be given a system of n (nonlinear) boundary conditions.
$g(y(a),y(b))=0$, $i=1,2,...,n$

where

$$y(x)=[y(x),y(x),...,y(x)]^T.$$  

The functions $g$ are evaluated by a subroutine $G$ supplied by the user. The solution is computed using a finite-difference technique with deferred correction allied to a Newton iteration to solve the finite-difference equations. The technique used is described fully in Pereyra [1].

The user must supply an absolute error tolerance and may also supply an initial mesh for the finite-difference equations and an initial approximate solution (alternatively a default mesh and approximation are used). The approximate solution is corrected using Newton iteration and deferred correction. Then, additional points are added to the mesh and the solution is recomputed with the aim of making the error everywhere less than the user's tolerance and of approximately equidistributing the error on the final mesh. The solution is returned on this final mesh.

If the solution is required at a few specific points then these should be included in the initial mesh. If, on the other hand, the solution is required at several specific points then the user should use the interpolation routines provided in Chapter E01 if these points do not themselves form a convenient mesh.

The Newton iteration requires Jacobian matrices

$${d\phi\over dx} = \left[\begin{array}{ccc} \frac{d\phi}{dy_1} & \frac{d\phi}{dy_2} & \cdots & \frac{d\phi}{dy_n} \\ \vdots & \vdots & \ddots & \vdots \\ \frac{d\phi}{dy_i} & \frac{d\phi}{dy_i} & \cdots & \frac{d\phi}{dy_i} \\ \frac{d\phi}{dy_j} & \frac{d\phi}{dy_j} & \cdots & \frac{d\phi}{dy_j} \end{array}\right].$$

These may be supplied by the user through subroutines JACDBF for $${d\phi\over dx} = \left[\begin{array}{ccc} \frac{d\phi}{dy_1} & \frac{d\phi}{dy_2} & \cdots & \frac{d\phi}{dy_n} \\ \vdots & \vdots & \ddots & \vdots \\ \frac{d\phi}{dy_i} & \frac{d\phi}{dy_i} & \cdots & \frac{d\phi}{dy_i} \\ \frac{d\phi}{dy_j} & \frac{d\phi}{dy_j} & \cdots & \frac{d\phi}{dy_j} \end{array}\right].$$

Alternatively the Jacobians $${d\phi\over dx} = \left[\begin{array}{ccc} \frac{d\phi}{dy_1} & \frac{d\phi}{dy_2} & \cdots & \frac{d\phi}{dy_n} \\ \vdots & \vdots & \ddots & \vdots \\ \frac{d\phi}{dy_i} & \frac{d\phi}{dy_i} & \cdots & \frac{d\phi}{dy_i} \\ \frac{d\phi}{dy_j} & \frac{d\phi}{dy_j} & \cdots & \frac{d\phi}{dy_j} \end{array}\right].$$

may be calculated by numerical differentiation using the algorithm described in Curtis et al [2].

For problems of the type (1) and (2) for which it is difficult to
determine an initial approximation from which the Newton
iteration will converge, a continuation facility is provided. The
user must set up a family of problems
\[ y' = f(x,y,(\epsilon)), \quad g(y(a),y(b),(\epsilon)) = 0, \quad (3) \]
where \( f = [f_1, f_2, \ldots, f_n] \) etc., and where \((\epsilon)\) is a
continuation parameter. The choice \((\epsilon) = 0\) must give a
problem (3) which is easy to solve and \((\epsilon) = 1\) must define
the problem whose solution is actually required. The routine
solves a sequence of problems with \((\epsilon)\) values
\[ 0 = (\epsilon_1) < (\epsilon_2) < \ldots < (\epsilon_p) = 1. \quad (4) \]
The number \( p \) and the values \((\epsilon)\) are chosen by the routine
so that each problem can be solved using the solution of its
predecessor as a starting approximation. Jacobians \( \frac{df}{d\epsilon} \)
and \( \frac{dg}{d\epsilon} \) are required and they may be supplied by the
user via routines JACEPS and JACGEP respectively or may be
computed by numerical differentiation.

5. Parameters

1: \( N \) -- INTEGER \hspace{1cm} \text{Input} \hspace{1cm} \text{Input}
\hspace{1cm} \text{On entry: the number of differential equations, n.}
\hspace{1cm} \text{Constraint: } N > 0.

2: \( MNP \) -- INTEGER
\hspace{1cm} \text{Input}
\hspace{1cm} \text{On entry: MNP must be set to the maximum permitted number}
of points in the finite-difference mesh. If LWORK or LIWORK (see below) is too small then internally MNP will be replaced by the maximum permitted by these values. (A warning message will be output if on entry IFAIL is set to obtain monitoring information.) Constraint: MNP >= 32.

3: NP -- INTEGER Input/Output
On entry: NP must be set to the number of points to be used in the initial mesh. Constraint: 4 <= NP <= MNP. On exit: the number of points in the final mesh.

4: NUMBEG -- INTEGER Input
On entry: the number of left-hand boundary conditions (that is the number involving y(a) only). Constraint: 0 <= NUMBEG < N.

5: NUMMIX -- INTEGER Input
On entry: the number of coupled boundary conditions (that is the number involving both y(a) and y(b)). Constraint: 0 <= NUMMIX <= N - NUMBEG.

6: TOL -- DOUBLE PRECISION Input
On entry: a positive absolute error tolerance. If 
\[ a = x < x_2 < \ldots < x_{NP} = b \]
is the final mesh, \( z_j(x) \) is the \( j \)th component of the \( i \)th approximate solution at \( x \), and \( y_i(x) \) is the \( j \)th component of the true solution of (1) and (2), then, except in extreme circumstances, it is expected that 
\[ |z_j(x_i) - y_j(x_i)| \leq TOL, \quad i=1,2,\ldots,\text{NP}; \quad j=1,2,\ldots,n. \] Constraint: TOL > 0.0.

7: INIT -- INTEGER Input
On entry: indicates whether the user wishes to supply an initial mesh and approximate solution (INIT /= 0) or whether default values are to be used, (INIT = 0).

8: X(MNP) -- DOUBLE PRECISION array Input/Output
On entry: the user must set \( x(1) = a \) and \( x(NP) = b \). If INIT = 0 on entry a default equispaced mesh will be used, otherwise the user must specify a mesh by setting \( x(i) = x_i \), for \( i = 2,3,\ldots,\text{NP}-1 \). Constraints: 
\( x(1) < x(\text{NP}) \), if INIT = 0,
\( x(1) < x(2) < \ldots < x(\text{NP}) \), if INIT /= 0.
On exit: \( x(1), x(2), \ldots, x(\text{NP}) \) define the final mesh (with
the returned value of NP) and X(1) = a and X(NP) = b.

9: Y(IY,MNP) -- DOUBLE PRECISION array Input/Output
On entry: if INIT = 0, then Y need not be set.
If INIT /= 0, then the array Y must contain an initial
approximation to the solution such that Y(j,i) contains an
approximation to
\[ y(x), i=1,2,...,NP; j=1,2,...,n. \]
On exit: the approximate solution \( z(x) \) satisfying (5) on
\[ y(x), i=1,2,...,NP; j=1,2,...,n. \]
where NP is the number of points in the final mesh. If an
error has occurred then Y contains the latest approximation
to the solution. The remaining columns of Y are not used.

10: IY -- INTEGER Input
On entry: the first dimension of the array Y as declared in the
(sub)program from which D02RAF is called.
Constraint: IY >= N.

11: ABT(N) -- DOUBLE PRECISION array Output
On exit: ABT(i), for i=1,2,...,n, holds the largest
estimated error (in magnitude) of the ith component of the
solution over all mesh points.

12: FCN -- SUBROUTINE, supplied by the user.
External Procedure
FCN must evaluate the functions f (i.e., the derivatives
\( y' \)) at a general point x for a given value of (epsilon),
the continuation parameter (see Section 3).

Its specification is:

```fortran
SUBROUTINE FCN (X, EPS, Y, F, N)
INTEGER N
DOUBLE PRECISION X, EPS, Y(N), F(N)

1: X -- DOUBLE PRECISION Input
On entry: the value of the argument x.

2: EPS -- DOUBLE PRECISION Input
On entry: the value of the continuation parameter,
(epsilon). This is 1 if continuation is not being used.
CHAPTER 22. NAG LIBRARY ROUTINES

3: Y(N) -- DOUBLE PRECISION array Input
    On entry: the value of the argument \( y \), for \( i = 1, 2, \ldots, n \).

4: F(N) -- DOUBLE PRECISION array Output
    On exit: the values of \( f \), for \( i = 1, 2, \ldots, n \).

5: N -- INTEGER Input
    On entry: the number of equations. FCN must be declared as EXTERNAL in the (sub)program
    from which D02RAF is called. Parameters denoted as Input must not be changed by this procedure.

13: G -- SUBROUTINE, supplied by the user. External Procedure
    G must evaluate the boundary conditions in equation (3) and
    place them in the array BC.

    Its specification is:

    SUBROUTINE G (EPS, YA, YB, BC, N)
    INTEGER N
    DOUBLE PRECISION EPS, YA(N), YB(N), BC(N)

1: EPS -- DOUBLE PRECISION Input
    On entry: the value of the continuation parameter, (epsilon). This is 1 if continuation is not being used.

2: YA(N) -- DOUBLE PRECISION array Input
    On entry: the value \( y(a) \), for \( i = 1, 2, \ldots, n \).

3: YB(N) -- DOUBLE PRECISION array Input
    On entry: the value \( y(b) \), for \( i = 1, 2, \ldots, n \).

4: BC(N) -- DOUBLE PRECISION array Output
    On exit: the values g \( (y(a),y(b),(\epsilon)) \), for \( i = 1, 2, \ldots, n \). These must be ordered as follows:
    (i) first, the conditions involving only y(a) (see NUMBEG description above);
    (ii) next, the NUMMIX coupled conditions involving both y(a) and y(b) (see NUMMIX description above); and,
(iii) finally, the conditions involving only \( y(b) \) (N- NUMBEG-NUMMIX).

5:  N -- INTEGER  
    On entry: the number of equations, n.

G must be declared as EXTERNAL in the (sub)program from
which D02RAF is called. Parameters denoted as Input
must not be changed by this procedure.

14:  IJAC -- INTEGER  
    On entry: indicates whether or not the user is supplying
Jacobian evaluation routines. If IJAC /= 0 then the user
must supply routines JACOF and JACOBG and also, when
continuation is used, routines JACEPS and JACGEP. If IJAC =
0 numerical differentiation is used to calculate the
Jacobian and the routines D02GAZ, D02GAY, D02GAZ and D02GAX

\[
\begin{align*}
\frac{d}{dx} 
\end{align*}
\]

JACOBF must evaluate the Jacobian \( \frac{d}{dy} \) for \( i,j=1,2,...,n \),

\[
\begin{align*}
\frac{d}{dy} 
\end{align*}
\]

given \( x \) and \( y \), for \( j=1,2,...,n \).

Its specification is:

\[
\begin{align*}
\text{SUBROUTINE JACOBF (X, EPS, Y, F, N)} \\
\text{INTEGER N} \\
\text{DOUBLE PRECISION X, EPS, Y(N), F(N,N)} \\
\end{align*}
\]

1:  X -- DOUBLE PRECISION  
    On entry: the value of the argument \( x \).

2:  EPS -- DOUBLE PRECISION  
    On entry: the value of the continuation parameter  
    (epsilon). This is 1 if continuation is not being used.

3:  Y(N) -- DOUBLE PRECISION array  
    On entry: the value of the argument \( y \), for
    \( i=1,2,...,n \).

4:  F(N,N) -- DOUBLE PRECISION array  
    Output
    On exit: \( F(i,j) \) must be set to the value of
    \( \frac{d}{dx} \),
    \( \frac{d}{dy} \)    
    evaluated at the point \( (x,y) \), for \( i,j=1,2,...,n \).
5:  N -- INTEGER  Input
    On entry: the number of equations, n.

JACOBF must be declared as EXTERNAL in the (sub)program from which D02RAF is called. Parameters denoted as Input must not be changed by this procedure.

16:  JACOBG -- SUBROUTINE, supplied by the user.

    External Procedure
    (  ddg  ) (  ddg  )
    (   i    ) (   i    )

JACOBG must evaluate the Jacobians (--------) and (--------)
( ddy (a)) ( ddy (b))
(   j    ) (   j    )

The ordering of the rows of AJ and BJ must correspond to the ordering of the boundary conditions described in the specification of subroutine G above.

Its specification is:

    SUBROUTINE JACOBG (EPS, YA, YB, AJ, BJ, N)
    INTEGER N
    DOUBLE PRECISION EPS, YA(N), YB(N), AJ(N,N), BJ(N,N)

1:  EPS -- DOUBLE PRECISION  Input
    On entry: the value of the continuation parameter, (epsilon). This is 1 if continuation is not being used.

2:  YA(N) -- DOUBLE PRECISION array  Input
    On entry: the value y (a), for i=1,2,...,n.
           i

3:  YB(N) -- DOUBLE PRECISION array  Input
    On entry: the value y (b), for i=1,2,...,n.
           i

4:  AJ(N,N) -- DOUBLE PRECISION array  Output
       ddg
       i
    On exit: AJ(i,j) must be set to the value (------),
             ddy (a)
             j
    for i,j=1,2,...,n.

5:  BJ(N,N) -- DOUBLE PRECISION array  Output
       ddg
       i
    On exit: BJ(i,j) must be set to the value (------),
             ddy (b)
             j
for \( i, j = 1, 2, \ldots, n \).

6: \( N \) -- INTEGER

\[
\text{Input}
\]
\[
\text{On entry: the number of equations, } n.
\]
\[
\text{JACOBG} \text{ must be declared as } \text{EXTERNAL} \text{ in the (sub)program from which } \text{D02RAF} \text{ is called. Parameters denoted as Input must not be changed by this procedure.}
\]

17: \( \text{DELEPS} \) -- DOUBLE PRECISION

\[
\text{Input/Output}
\]
\[
\text{On entry: } \text{DELEPS} \text{ must be given a value which specifies whether continuation is required. If } \text{DELEPS} \leq 0.0 \text{ or } \text{DELEPS} \geq 1.0 \text{ then it is assumed that continuation is not required. If } 0.0 < \text{DELEPS} < 1.0 \text{ then it is assumed that continuation is required unless } \text{DELEPS} < \text{square root of machine precision when an error exit is taken. } \text{DELEPS} \text{ is used as the increment } (\epsilon)_{p-1} \text{ (see (4)) and the choice } \text{DELEPS} = 0.1 \]
\[
\text{is recommended. On exit: an overestimate of the increment } (\epsilon)_{p} \text{ (in fact the value of the increment }
\]
\[
\frac{1}{p-1}
\]
\[
\text{which would have been tried if the restriction } (\epsilon)_{p} = 1
\]
\[
\text{had not been imposed). If continuation was not requested then } \text{DELEPS} = 0.0.
\]

If continuation is not requested then the parameters \( \text{JACEPS} \) and \( \text{JACGEP} \) may be replaced by dummy actual parameters in the call to \( \text{D02RAF} \). \( \text{D02GAZ and D02GAX respectively may be used as the dummy parameters.} \)

18: \( \text{JACEPS} \) -- SUBROUTINE, supplied by the user.

\[
\text{External Procedure}
\]
\[
\text{ddf}_{i}
\]
\[
\text{JACEPS} \text{ must evaluate the derivative } \frac{\text{d}y}{\text{d}x} \text{ given } x \text{ and } (\epsilon)_{p-1}
\]

\[
\text{y if continuation is being used.}
\]

\[
\text{Its specification is:}
\]
\[
\text{SUBROUTINE JACEPS (X, EPS, Y, F, N)}
\]
\[
\text{INTEGER N}
\]
\[
\text{DOUBLE PRECISION X, EPS, Y(N), F(N)}
\]

1: \( X \) -- DOUBLE PRECISION

\[
\text{Input}
\]
\[
\text{On entry: the value of the argument } x.
\]

2: \( EPS \) -- DOUBLE PRECISION

\[
\text{Input}
\]
\[
\text{On entry: the value of the continuation parameter, } (\epsilon).
\]
3: Y(N) -- DOUBLE PRECISION array  
   On entry: the solution values \( y_i \) at the point \( x \), for \( i = 1, 2, \ldots, n \).

4: F(N) -- DOUBLE PRECISION array  
   Output
   On exit: \( F(i) \) must contain the value \( \frac{dF}{d\epsilon} \) at the point \((x, y)\), for \( i = 1, 2, \ldots, n \).

5: N -- INTEGER  
   Input
   On entry: the number of equations, \( n \).

JACEPS must be declared as EXTERNAL in the (sub)program from which D02RAF is called. Parameters denoted as Input must not be changed by this procedure.

19: JACGEP -- SUBROUTINE, supplied by the user.  
   External Procedure
   JACGEP must evaluate the derivatives \( \frac{dF}{d\epsilon} \) if continuation is being used.

Its specification is:

\[
\text{SUBROUTINE JACGEP (EPS, YA, YB, BCEP, N)}
\]

\[
\text{INTEGER N}
\]

\[
\text{DOUBLE PRECISION EPS, YA(N), YB(N), BCEP(N)}
\]

1: EPS -- DOUBLE PRECISION  
   Input
   On entry: the value of the continuation parameter, \( \epsilon \).

2: YA(N) -- DOUBLE PRECISION array  
   Input
   On entry: the value of \( y_i(a) \), for \( i = 1, 2, \ldots, n \).

3: YB(N) -- DOUBLE PRECISION array  
   Input
   On entry: the value of \( y_i(b) \), for \( i = 1, 2, \ldots, n \).

4: BCEP(N) -- DOUBLE PRECISION array  
   Output
   On exit: \( BCEP(i) \) must contain the value of \( \frac{d\epsilon}{dG} \) \( i \), for \( i = 1, 2, \ldots, n \).
dd(epsilon)

5: N -- INTEGER Input
   On entry: the number of equations, n.
   JACGEP must be declared as EXTERNAL in the (sub)program
   from which D02RAF is called. Parameters denoted as
   Input must not be changed by this procedure.

20: WORK(LWORK) -- DOUBLE PRECISION array Workspace

21: LWORK -- INTEGER Input
   On entry:
   the dimension of the array WORK as declared in the
   (sub)program from which D02RAF is called.
   Constraint: LWORK>=MNP*(3N +6N+2)+4N +3N.

22: IWORK(LIWORK) -- INTEGER array Workspace

23: LIWORK -- INTEGER Input
   On entry:
   the dimension of the array IWORK as declared in the
   (sub)program from which D02RAF is called.
   Constraints:
   LIWORK>=MNP*(2*N+1)+N, if IJAC /= 0,
   LIWORK>=MNP*(2*N+1)+N +4*N+2, if IJAC = 0.

24: IFAIL -- INTEGER Input/Output
   For this routine, the normal use of IFAIL is extended to
   control the printing of error and warning messages as well
   as specifying hard or soft failure (see the Essential
   Introduction).

   Before entry, IFAIL must be set to a value with the decimal
   expansion cba, where each of the decimal digits c, b and a
   must have a value of 0 or 1.
   a=0 specifies hard failure, otherwise soft failure;
   b=0 suppresses error messages, otherwise error messages
   will be printed (see Section 6);
   c=0 suppresses warning messages, otherwise warning
   messages will be printed (see Section 6).
   The recommended value for inexperienced users is 110 (i.e.,
   hard failure with all messages printed).

   Unless the routine detects an error (see Section 6), IFAIL
   contains 0 on exit.
6. Error Indicators and Warnings

Errors detected by the routine:

For each error, an explanatory error message is output on the current error message unit (as defined by X04AAF), unless suppressed by the value of IFAIL on entry.

IFAIL= 1
One or more of the parameters N, MNP, NP, NUMBEG, NUMMIX, TOL, DELEPS, LWORK or LIWORK has been incorrectly set, or X(1) >= X(NP) or the mesh points X(i) are not in strictly ascending order.

IFAIL= 2
A finer mesh is required for the accuracy requested; that is MNP is not large enough. This error exit normally occurs when the problem being solved is difficult (for example, there is a boundary layer) and high accuracy is requested. A poor initial choice of mesh points will make this error exit more likely.

IFAIL= 3
The Newton iteration has failed to converge. There are several possible causes for this error:

(i) faulty coding in one of the Jacobian calculation routines;

(ii) if IJAC = 0 then inaccurate Jacobians may have been calculated numerically (this is a very unlikely cause); or,

(iii) a poor initial mesh or initial approximate solution has been selected either by the user or by default or there are not enough points in the initial mesh. Possibly, the user should try the continuation facility.

IFAIL= 4
The Newton iteration has reached round-off error level. It could be however that the answer returned is satisfactory. The error is likely to occur if too high an accuracy is requested.

IFAIL= 5
The Jacobian calculated by JACOBG (or the equivalent matrix calculated by numerical differentiation) is singular. This may occur due to faulty coding of JACOBG or, in some circumstances, to a zero initial choice of approximate
solution (such as is chosen when INIT = 0).

IFAIL= 6  
There is no dependence on (epsilon) when continuation is  
being used. This can be due to faulty coding of JACEPS or  
JACGEP or, in some circumstances, to a zero initial choice  
of approximate solution (such as is chosen when INIT = 0).

IFAIL= 7  
DELEPS is required to be less than machine precision for  
continuation to proceed. It is likely that either the  
problem (3) has no solution for some value near the current  
value of (epsilon) (see the advisory print out from D02RAF)  
or that the problem is so difficult that even with  
continuation it is unlikely to be solved using this routine.  
If the latter cause is suspected then using more mesh points  
initially may help.

IFAIL= 8  
Indicates that a serious error has occurred in a call to  
D02RAF. Check all array subscripts and subroutine parameter  
lists in calls to D02RAF. Seek expert help.

IFAIL= 9  
Indicates that a serious error has occurred in a call to  
D02RAR. Check all array subscripts and subroutine parameter  
lists in calls to D02RAF. Seek expert help.

7. Accuracy

The solution returned by the routine will be accurate to the  
user's tolerance as defined by the relation (5) except in extreme  
circumstances. The final error estimate over the whole mesh for  
each component is given in the array ABT. If too many points are  
specified in the initial mesh, the solution may be more accurate  
than requested and the error may not be approximately  
equidistributed.

8. Further Comments

There are too many factors present to quantify the timing. The  
time taken by the routine is negligible only on very simple  
problems.

The user is strongly recommended to set IFAIL to obtain self-  
explanatory error messages, and also monitoring information about  
the course of the computation.

In the case where the user wishes to solve a sequence of similar  
problems, the use of the final mesh and solution from one case as
the initial mesh is strongly recommended for the next.

9. Example

We solve the differential equation

\[ y'''' = -yy''' - 2(\epsilon)(1-y') \]

with \((\epsilon) = 1\) and boundary conditions

\[ y(0) = y'(0) = 0, \quad y'(10) = 1 \]

to an accuracy specified by \(TOL = 1.0E-4\). The continuation facility is used with the continuation parameter \((\epsilon)\) introduced as in the differential equation above and with \(DELEPS = 0.1\) initially. (The continuation facility is not needed for this problem and is used here for illustration.)

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

\begin{verbatim}
D03(3NAG) Foundation Library (12/10/92) D03(3NAG)

D03 -- Partial Differential Equations Introduction -- D03
Chapter D03
Partial Differential Equations
\end{verbatim}
1. Scope of the Chapter

This chapter is concerned with the solution of partial differential equations.

2. Background to the Problems

The definition of a partial differential equation problem includes not only the equation itself but also the domain of interest and appropriate subsidiary conditions. Indeed, partial differential equations are usually classified as elliptic, hyperbolic or parabolic according to the form of the equation and the form of the subsidiary conditions which must be assigned to produce a well-posed problem. Ultimately it is hoped that this chapter will contain routines for the solution of equations of each of these types together with automatic mesh generation routines and other utility routines particular to the solution of partial differential equations. The routines in this chapter will often call upon routines from the Linear Algebra Chapter F04 -- Simultaneous Linear Equations.

The classification of partial differential equations is easily described in the case of linear equations of the second order in two independent variables, i.e., equations of the form

\[ au + 2bu + cu + du + eu + fu + g = 0, \]  
\[ xx \ xy \ yy \ x \ y \]

where \( a, b, c, d, e, f \) and \( g \) are functions of \( x \) and \( y \) only. Equation (1) is called elliptic, hyperbolic or parabolic according as \( ac-b^2 \) is positive, negative or zero. Useful definitions of the concepts of elliptic, hyperbolic and parabolic character can also be given for differential equations in more than two independent variables, for systems and for nonlinear differential equations.

For elliptic equations, of which Laplace's equation

\[ u + u = 0 \]  
\[ xx \ yy \]

is the simplest example of second order, the subsidiary conditions take the form of boundary conditions, i.e., conditions which provide information about the solution at all points of a closed boundary. For example, if equation (2) holds in a plane domain \( D \) bounded by a contour \( C \), a solution \( u \) may be sought subject to the condition

\[ u = f \text{ on } C, \]  
\[ (3) \]
where \( f \) is a given function. The condition (3) is known as a Dirichlet boundary condition. Equally common is the Neumann boundary condition

\[
u' = g \quad \text{on } C, \tag{4}\]

which is one form of a more general condition

\[
u' + fu = g \quad \text{on } C, \tag{5}\]

where \( u' \) denotes the derivative of \( u \) normal to the contour \( C \) and \( f \) and \( g \) are given functions. Provided that \( f \) and \( g \) satisfy certain restrictions, condition (5) yields a well-posed boundary value problem for Laplace’s equation. In the case of the Neumann problem, one further piece of information, e.g. the value of \( u \) at a particular point, is necessary for uniqueness of the solution. Boundary conditions similar to the above are applicable to more general second order elliptic equations, whilst two such conditions are required for equations of fourth order.

For hyperbolic equations, the wave equation

\[
u - \frac{\partial u}{\partial t} = 0, \quad \frac{\partial^2 u}{\partial x^2} = 0 \tag{6}\]

is the simplest example of second order. It is equivalent to a first order system

\[
u - \frac{\partial v}{\partial t} = 0, \quad \frac{\partial v}{\partial x} - \frac{\partial u}{\partial t} = 0. \tag{7}\]

The subsidiary conditions may take the form of initial conditions, i.e., conditions which provide information about the solution at points on a suitable open boundary. For example, if equation (6) is satisfied for \( t > 0 \), a solution \( u \) may be sought such that

\[
u(x,0) = f(x), \quad \frac{\partial u}{\partial t}(x,0) = g(x), \tag{8}\]

where \( f \) and \( g \) are given functions. This is an example of an initial value problem, sometimes known as Cauchy’s problem.

For parabolic equations, of which the heat conduction equation

\[
u - \frac{\partial u}{\partial t} = 0 \quad \frac{\partial^2 u}{\partial x^2} = 0 \tag{9}\]

is the simplest example, the subsidiary conditions always include
some of initial type and may also include some of boundary type. For example, if equation (9) is satisfied for t>0 and 0<x<1, a solution u may be sought such that

\[ u(x,0)=f(x), \quad 0<x<1, \quad (10) \]

and

\[ u(0,t)=0, \quad u(1,t)=1, \quad t>0. \quad (11) \]

This is an example of a mixed initial/boundary value problem.

For all types of partial differential equations, finite difference methods (Mitchell and Griffiths [5]) and finite element methods (Wait and Mitchell [9]) are the most common means of solution and such methods obviously feature prominently either in this chapter or in the companion NAG Finite Element Library. Many of the utility routines in this chapter are concerned with the solution of the large sparse systems of equations which arise from the finite difference and finite element methods.

Alternative methods of solution are often suitable for special classes of problems. For example, the method of characteristics is the most common for hyperbolic equations involving time and one space dimension (Smith [7]). The method of lines (see Mikhlin and Smolitsky [4]) may be used to reduce a parabolic equation to a (stiff) system of ordinary differential equations, which may be solved by means of routines from Chapter D02 -- Ordinary Differential Equations. Similarly, integral equation or boundary element methods (Jaswon and Symm [3]) are frequently used for elliptic equations. Typically, in the latter case, the solution of a boundary value problem is represented in terms of certain boundary functions by an integral expression which satisfies the differential equation throughout the relevant domain. The boundary functions are obtained by applying the given boundary conditions to this representation. Implementation of this method necessitates discretisation of only the boundary of the domain, the dimensionality of the problem thus being effectively reduced by one. The boundary conditions yield a full system of simultaneous equations, as opposed to the sparse systems yielded by the finite difference and finite element methods, but the full system is usually of much lower order. Solution of this system yields the boundary functions, from which the solution of the problem may be obtained, by quadrature, as and where required.

2.1. References

3. Recommendations on Choice and Use of Routines

The choice of routine will depend first of all upon the type of partial differential equation to be solved. At present no special allowances are made for problems with boundary singularities such as may arise at corners of domains or at points where boundary conditions change. For such problems results should be treated with caution.

Users may wish to construct their own partial differential equation solution software for problems not solvable by the routines described in Sections 3.1 to 3.4 below. In such cases users can employ appropriate routines from the Linear Algebra Chapters to solve the resulting linear systems; see Section 3.5 for further details.

3.1. Elliptic Equations

The routine D03EDF solves a system of seven-point difference equations in a rectangular grid (in two dimensions), using the multigrid iterative method. The equations are supplied by the user, and the seven-point form allows cross-derivative terms to
be represented (see Mitchell and Griffiths [5]). The method is particularly efficient for large systems of equations with diagonal dominance.

The routine D03EEF discretises a second-order equation on a two-dimensional rectangular region using finite differences and a seven-point molecule. The routine allows for cross-derivative terms, Dirichlet, Neumann or mixed boundary conditions, and either central or upwind differences. The resulting seven-diagonal difference equations are in a form suitable for passing directly to the multigrid routine D03EDF, although other solution methods could easily be used.

The routine D03FAF, based on the routine HW3CRT from FISHPACK (Swartztrauber and Sweet [8]), solves the Helmholtz equation in a three-dimensional cuboidal region, with any combination of Dirichlet, Neumann or periodic boundary conditions. The method used is based on the fast Fourier transform algorithm, and is likely to be particularly efficient on vector-processing machines.

3.2. Hyperbolic Equations

There are no routines available yet for the solution of these equations.

3.3. Parabolic Equations

There are no routines available yet for the solution of these equations.

But problems in two space dimensions plus time may be treated as a succession of elliptic equations [1], [6] using appropriate D03E- routines or one may use codes from the NAG Finite Element Library.

3.4. Utility Routines

There are no utility routines available yet, but routines are available in the Linear Algebra Chapters for the direct and iterative solution of linear equations. Here we point to some of the routines that may be of use in solving the linear systems that arise from finite difference or finite element approximations to partial differential equation solutions. Chapters F01 and F04 should be consulted for further information and for the routine documents. Decision trees for the solution of linear systems are given in Section 3.5 of the F04 Chapter Introduction.

The following routines allow the direct solution of symmetric
positive-definite systems:

- **Band** 
  - F04ACF
- **Variable band (skyline)** 
  - F01MCF and F04MCF
- **Tridiagonal** 
  - F04FAF
- **Sparse** 
  - F01MAF* and F04MAF

(* the parameter DROPTL should be set to zero for F01MAF to give a direct solution)

and the following routines allow the iterative solution of symmetric positive-definite systems:

- **Sparse (incomplete)** 
  - F01MAF and F04MBF
  - Cholesky

- **Sparse (conjugate gradient)** 
  - F04MBF

The latter routine above allows the user to supply a pre-conditioner and also allows the solution of indefinite symmetric systems.

The following routines allow the direct solution of unsymmetric systems:

- **Band** 
  - F01LBF and F04LDF
- **Almost block-diagonal** 
  - F01LHF and F04LHF
- **Tridiagonal** 
  - F01LEF and F04LEF or F04EAF
- **Sparse** 
  - F01BRF (and F01BSF) and F04AXF

and the following routine allows the iterative solution of unsymmetric systems:

- **Sparse** 
  - F04QAF

The above routine allows the user to supply a pre-conditioner and also allows the solution of least-squares systems.

Discrete elliptic PDE on rectangular region

--- nagd.ht ---
CHAPTER 22. NAG LIBRARY ROUTINES

not included in the Foundation Library.

1. Purpose
D03EDF solves seven-diagonal systems of linear equations which arise from the discretization of an elliptic partial differential equation on a rectangular region. This routine uses a multigrid technique.

2. Specification

```fortran
SUBROUTINE D03EDF (NGX, NGY, LDA, A, RHS, UB, MAXIT, ACC, 1 US, U, IOUT, NUMIT, IFAIL)
INTEGER NGX, NGY, LDA, MAXIT, IOUT, NUMIT, IFAIL
DOUBLE PRECISION A(LDA,7), RHS(LDA), UB(NGX*NGY), ACC, US 1 (LDA), U(LDA)
```

3. Description
D03EDF solves, by multigrid iteration, the seven-point scheme

$$
\begin{align*}
A u & + A u \\
i,j & i-1,j+1 i,j & i,j & i,j+1 \\
& A u + A u + A u \\
i,j & i,j & i,j & i,j & i,j+1 \\
& A u + A u + A u \\
1 & 1 & 2 & 3 & 4 & 5 \\
i,j & i,j & i,j-1 & i,j & i,j+1 \\
& A u + A u = f \\
i,j & i,j & i,j & i,j & i,j & i,j & i,j & i=1,2,...,n ; j=1,2,...,n , \\
& x & y
\end{align*}
$$

which arises from the discretization of an elliptic partial differential equation of the form

$$
(\alpha)(x,y)U + (\beta)(x,y)U + (\gamma)(x,y)U + (\delta)(x,y)U + (\epsilon)(x,y)U + (\phi)(x,y)U = (\psi)(x,y)
$$

and its boundary conditions, defined on a rectangular region. This we write in matrix form as

$$
Au = f
$$
The algorithm is described in separate reports by Wesseling [2], [3] and McCarthy [1].

Systems of linear equations, matching the seven-point stencil defined above, are solved by a multigrid iteration. An initial estimate of the solution must be provided by the user. A zero guess may be supplied if no better approximation is available.

A 'smoother' based on incomplete Crout decomposition is used to eliminate the high frequency components of the error. A restriction operator is then used to map the system on to a sequence of coarser grids. The errors are then smoothed and prolonged (mapped onto successively finer grids). When the finest cycle is reached, the approximation to the solution is corrected. The cycle is repeated for MAXIT iterations or until the required accuracy, ACC, is reached.

D03EDF will automatically determine the number l of possible coarse grids, 'levels' of the multigrid scheme, for a particular problem. In other words, D03EDF determines the maximum integer l so that n and n can be expressed in the form

\[
x y
\]

\[
l-1 l-1
n = m^2 + 1, n = n^2 + 1, \text{ with } m \geq 2 \text{ and } n \geq 2.
\]

It should be noted that the rate of convergence improves significantly with the number of levels used (see McCarthy [1]), so that n and n should be carefully chosen so that n -1 and

\[
x y
\]

\[
l
n -1 \text{ have factors of the form } 2^x, \text{ with } l \text{ as large as possible.}
\]

For good convergence the integer l should be at least 2.

D03EDF has been found to be robust in application, but being an iterative method the problem of divergence can arise. For a strictly diagonally dominant matrix A

\[
\begin{bmatrix}
4 & k \\
ij & \ldots & ij \\
|A| & \ldots & |A| \\
\end{bmatrix}
\]

\[
\begin{bmatrix}
\vdots \\
\end{bmatrix}
\]

\[
k/4
\]

no such problem is foreseen. The diagonal dominance of A is not a necessary condition, but should this condition be strongly violated then divergence may occur. The quickest test is to try
4. References

5. Parameters

1: NGX -- INTEGER Input
On entry: the number of interior grid points in the x-direction, n. NGX-1 should preferably be divisible by as high a power of 2 as possible. Constraint: NGX >= 3.

2: NGY -- INTEGER Input
On entry: the number of interior grid points in the y-direction, n. NGY-1 should preferably be divisible by as high a power of 2 as possible. Constraint: NGY >= 3.

3: LDA -- INTEGER Input
On entry: the first dimension of the array A as declared in the (sub)program from which D03EDF is called, which must also be a lower bound for the dimensions of the arrays RHS, US and U. It is always sufficient to set LDA>=4*(NGX+1)*(NGY+1))/3, but slightly smaller values may be permitted, depending on the values of NGX and NGY. If on entry, LDA is too small, an error message gives the minimum permitted value. (LDA must be large enough to allow space for the coarse-grid approximations).

4: A(LDA,7) -- DOUBLE PRECISION array Input/Output
On entry: A(i+(j-1)*NGX,k) must be set to A, for i = 1,2,...,NGX; j = 1,2,...,NGY and k = 1,2,...,7. On exit: A is overwritten.

5: RHS(LDA) -- DOUBLE PRECISION array Input/Output
On entry: RHS(i+(j-1)*NGX) must be set to f, for i = 1,2,...,NGX; j = 1,2,...,NGY. On exit: the first NGX*NGY
elements are unchanged and the rest of the array is used as workspace.

6: UB(NGX*NGY) -- DOUBLE PRECISION array          Input/Output
On entry: UB(i+(j-1)*NGX) must be set to the initial
estimate for the solution u. On exit: the corresponding
\( i, j \)
component of the residual \( r = f - Au \).

7: MAXIT -- INTEGER           Input
On entry: the maximum permitted number of multigrid
iterations. If MAXIT = 0, no multigrid iterations are
performed, but the coarse-grid approximations and incomplete
Crout decompositions are computed, and may be output if IOUT
is set accordingly. Constraint: MAXIT \geq 0.

8: ACC -- DOUBLE PRECISION     Input
On entry: the required tolerance for convergence of the
residual 2-norm:

\[
\|r\|_2 = \sqrt{\sum_{k=1}^{NGX*NGY} r_k^2}
\]

where \( r = f - Au \) and \( u \) is the computed solution. Note that the
norm is not scaled by the number of equations. The routine
will stop after fewer than MAXIT iterations if the residual
2-norm is less than the specified tolerance. (If MAXIT > 0,
at least one iteration is always performed.)

If on entry ACC = 0.0, then the machine precision is used as
a default value for the tolerance; if ACC > 0.0, but ACC is
less than the machine precision, then the routine will stop
when the residual 2-norm is less than the machine precision
and IFAIL will be set to 4. Constraint: ACC \geq 0.0.

9: US(LDA) -- DOUBLE PRECISION array         Output
On exit: the residual 2-norm, stored in element US(1).

10: U(LDA) -- DOUBLE PRECISION array         Output
On exit: the computed solution \( u \) is returned in \( U(i+(j-1)*)NGX) \), for \( i = 1,2,\ldots,NGX; j = 1,2,\ldots,NGY \).

11: IOUT -- INTEGER         Input
On entry: controls the output of printed information to the
advisory message unit as returned by X04ABF:
IOUT = 0
No output.

IOUT = 1
The solution $u_{ij}$ for $i = 1, 2, ..., NGX; j = 1, 2, ..., NGY$.

IOUT = 2
The residual 2-norm after each iteration, with the reduction factor over the previous iteration.

IOUT = 3
As for IOUT = 1 and IOUT = 2.

IOUT = 4
As for IOUT = 3, plus the final residual (as returned in UB).

IOUT = 5
As for IOUT = 4, plus the initial elements of A and RHS.

IOUT = 6
As for IOUT = 5, plus the Galerkin coarse grid approximations.

IOUT = 7
As for IOUT = 6, plus the incomplete Crout decompositions.

IOUT = 8
As for IOUT = 7, plus the residual after each iteration.

The elements $A(p,k)$, the Galerkin coarse grid approximations and the incomplete Crout decompositions are output in the format:

$Y$-index = $j$
$X$-index = $i$
$A(p,1)$ $A(p,2)$ $A(p,3)$ $A(p,4)$ $A(p,5)$ $A(p,6)$ $A(p,7)$

where $p = i + (j-1) \times NGX$, $i = 1, 2, ..., NGX$ and $j = 1, 2, ..., NGY$.

The vectors $U(p)$, $UB(p)$, $RHS(p)$ are output in matrix form with NGY rows and NGX columns. Where NGX > 10, the NGX values for a given j-value are produced in rows of 10. Values of IOUT > 4 may yield considerable amounts of output. Constraint: $0 \leq IOUT \leq 8$.

12: NUMIT -- INTEGER  
Output
On exit: the number of iterations performed.

13: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1
On entry NGX < 3,

or NGY < 3,

or LDA is too small,

or ACC < 0.0,

or MAXIT < 0,

or IOUT < 0,

or IOUT > 8.

IFAIL= 2
MAXIT iterations have been performed with the residual 2-norm decreasing at each iteration but the residual 2-norm has not been reduced to less than the specified tolerance (see ACC). Examine the progress of the iteration by setting IOUT >= 2.

IFAIL= 3
As for IFAIL = 2, except that at one or more iterations the residual 2-norm did not decrease. It is likely that the method fails to converge for the given matrix A.

IFAIL= 4
On entry ACC is less than the machine precision. The routine terminated because the residual norm is less than the machine precision.

7. Accuracy
See ACC (Section 5).

8. Further Comments

The rate of convergence of this routine is strongly dependent upon the number of levels, \( l \), in the multigrid scheme, and thus the choice of \( \text{NGX} \) and \( \text{NGY} \) is very important. The user is advised to experiment with different values of \( \text{NGX} \) and \( \text{NGY} \) to see the effect they have on the rate of convergence; for example, using a value such as \( \text{NGX} = 65 \) (=2 +1) followed by \( \text{NGX} = 64 \) (for which \( l = 1 \)).

9. Example

The program solves the elliptic partial differential equation

\[
\begin{align*}
U &= -(\alpha)U + U = -4, \quad (\alpha) = 1.7 \\
\frac{\partial^2 U}{\partial x^2} + \frac{\partial^2 U}{\partial y^2} &= 0 \\
\end{align*}
\]

on the unit square \( 0 \leq x, y \leq 1 \), with boundary conditions

\[
\begin{align*}
\{x = 0, \quad 0 \leq y \leq 1\} \\
U = 0 \quad \{y = 0, \quad 0 \leq x \leq 1\} \\
U = 1 \quad \{x = 1, \quad 0 \leq y \leq 1\} \\
\{y = 1, \quad 0 \leq x \leq 1\} \\
\end{align*}
\]

For the equation to be elliptic, \( \alpha \) must be less than 2.

The equation is discretized on a square grid with mesh spacing \( h \) in both directions using the following approximations:

Please see figure in printed Reference Manual

\[
\begin{align*}
1 \\
U &= -((U - 2U + U) \\
xx &= (2 E \quad 0 \quad W) \\
h &= 1 \\
1 \\
U &= -((U - 2U + U) \\
xy &= (2 N \quad 0 \quad S) \\
h &= 1 \\
U &= ---((U - U + U - 2U + U - U + U) \\
xy &= (2 N \quad NW \quad E \quad 0 \quad W \quad SE \quad S) \\
2h &= \end{align*}
\]
Thus the following equations are solved:

\[
\begin{align*}
1 & \quad -(\alpha)u + (1 - (\alpha))u \\
2 & \quad i-1,j+1 \quad 2 \quad i,j+1 \\

1 & \quad + (1 - (\alpha))u + (-4 + (\alpha))u + (1 - (\alpha))u \\
2 & \quad i-1,j \quad ij \quad 2 \quad i+1,j \\

1 & \quad + (1 - (\alpha))u + (-\alpha)u \\
2 & \quad i,j-1 \quad 2 \quad i+1,j-1
\end{align*}
\]

\[= -4h\]

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

D03EEF discretizes a second order elliptic partial differential equation (PDE) on a rectangular region.

2. Specification

```fortran
SUBROUTINE D03EEF (XMIN, XMAX, YMIN, YMAX, PDEF, BNDY, 1 NGX, NGY, LDA, A, RHS, SCHEME, IFAIL)
INTEGER NGX, NGY, LDA, IFAIL
DOUBLE PRECISION XMIN, XMAX, YMIN, YMAX, A(LDA,7), RHS(LDA)
CHARACTER*1 SCHEME
EXTERNAL PDEF, BNDY
```

3. Description

D03EEF discretizes a second order linear elliptic partial differential equation of the form

\[
\begin{align*}
\frac{\partial^2 U}{\partial x^2} &+ \frac{\partial^2 U}{\partial y^2} \\
\frac{\partial \frac{\partial U}{\partial x}}{\partial x} &+ \frac{\partial \frac{\partial U}{\partial y}}{\partial y} \\
\end{align*}
\]

\begin{align*}
\alpha(x,y) \frac{\partial^2 U}{\partial x^2} + \beta(x,y) \frac{\partial^2 U}{\partial y^2} + \gamma(x,y) \frac{\partial \frac{\partial U}{\partial x}}{\partial x} + \delta(x,y) \frac{\partial \frac{\partial U}{\partial y}}{\partial y} + \epsilon(x,y) \frac{\partial U}{\partial x} + \phi(x,y) = \psi(x,y)
\end{align*}

on a rectangular region

\[
\begin{align*}
x &\leq x \leq x \\
A & B \\
y &\leq y \leq y \\
A & B
\end{align*}
\]

subject to boundary conditions of the form

\[
\begin{align*}
\frac{\partial U}{\partial n} \\
a(x,y)U + b(x,y) = c(x,y)
\end{align*}
\]
22.3. NAGDHT

\[ \frac{\partial^2 U}{\partial n} \]

where \( \partial \) denotes the outward pointing normal derivative on the boundary. Equation (1) is said to be elliptic if

\[ 4(\alpha(x,y)\gamma(x,y)) \geq (\beta(x,y)) \]

for all points in the rectangular region. The linear equations produced are in a form suitable for passing directly to the multigrid routine D03EDF.

The equation is discretized on a rectangular grid, with \( n_x \) grid points in the \( x \)-direction and \( n_y \) grid points in the \( y \)-direction.

The grid spacing used is therefore

\[
\begin{align*}
  h_x &= (x_B - x_A) / (n_x - 1) \\
  h_y &= (y_B - y_A) / (n_y - 1)
\end{align*}
\]

and the co-ordinates of the grid points \( (x_i, y_j) \) are

\[
\begin{align*}
  x_i &= x_A + (i-1)h_x, \quad i=1,2,\ldots,n_x \\
  y_j &= y_A + (j-1)h_y, \quad j=1,2,\ldots,n_y
\end{align*}
\]

At each grid point \( (x_i, y_j) \) six neighbouring grid points are used to approximate the partial differential equation, so that the equation is discretized on the following seven-point stencil:

Please see figure in printed Reference Manual

For convenience the approximation \( u_{ij} \) to the exact solution \( U(x_i, y_j) \) is denoted by \( u_{ij} \), and the neighbouring approximations are labelled according to points of the compass as shown. Where numerical labels for the seven points are required, these are also shown above.
The following approximations are used for the second derivatives:

\[
\begin{align*}
\frac{2}{
\frac{d^2 U}{dx^2}} &\approx -\frac{u_{-2} - 2u_x + u_{2}}{h^2}, \\
\frac{2}{
\frac{d^2 U}{dy^2}} &\approx -\frac{u_{-2} - 2u_y + u_{2}}{h^2}, \\
\frac{2}{
\frac{d^2 U}{dxdy}} &\approx -\frac{u_{-2} - 2u_{-2} + u_{2} - 2u_x + u_y - 2u_y + u_{2}}{h^2}.
\end{align*}
\]

Two possible schemes may be used to approximate the first derivatives:

**Central Differences**

\[
\begin{align*}
\frac{dU}{dx} &\approx -\frac{u_{-1} - u_1}{2h}, \\
\frac{dU}{dy} &\approx -\frac{u_{-1} - u_1}{2h}.
\end{align*}
\]

**Upwind Differences**

\[
\begin{align*}
\frac{dU}{dx} &\approx -\frac{u_{-1} - u_1}{h} \text{ if } (\delta)(x,y) > 0, \\
\frac{dU}{dx} &\approx -\frac{u_{-1} - u_1}{h} \text{ if } (\delta)(x,y) < 0.
\end{align*}
\]
Central differences are more accurate than upwind differences, but upwind differences may lead to a more diagonally dominant matrix for those problems where the coefficients of the first derivatives are significantly larger than the coefficients of the second derivatives.

The approximations used for the first derivatives may be written in a more compact form as follows:

\[
\frac{d^2 u}{d x^2} = \frac{(k - 1)u - 2k u + (k + 1)u}{2h} \quad (x \text{ W x O x E})
\]

\[
\frac{d^2 u}{d y^2} = \frac{(k - 1)u - 2k u + (k + 1)u}{2h} \quad (y \text{ S y O y N})
\]

where \( k = \text{sign}(\delta) \) and \( k = \text{sign}(\epsilon) \) for upwind differences, and \( k = k = 0 \) for central differences.

At all points in the rectangular domain, including the boundary, the coefficients in the partial differential equation are evaluated by calling the user-supplied subroutine PDEF, and applying the approximations. This leads to a seven-diagonal system of linear equations of the form:

\[
\begin{align*}
6 & & 7 \\
A & u & +A & u \\
i & i-1,j+1 & i & i,j+1 \\
3 & 4 & 5 \\
\end{align*}
\]

\[
\begin{align*}
+ & A & u & +A & u & +A & u \\
i & i-1,j & i & j & i & i+1,j \\
1 & 2 \\
\end{align*}
\]

\[
\begin{align*}
+ & A & u & +A & u \\
i & i,j-1 & i & i+1,j-1 & i & j \\
\end{align*}
\]

\[
= f, \quad i=1,2,\ldots,n; \quad j=1,2,\ldots,n,
\]

where the coefficients are given by
These equations then have to be modified to take account of the
boundary conditions. These may be Dirichlet (where the solution
is given), Neumann (where the derivative of the solution is
given), or mixed (where a linear combination of solution and
derivative is given).

If the boundary conditions are Dirichlet, there are an infinity
of possible equations which may be applied:

\[ (\mu) u_{ij} = (\mu) f_{ij} , \quad (\mu) = 0. \]  (2)

If DO3EDF is used to solve the discretized equations, it turns
out that the choice of \((\mu)\) can have a dramatic effect on the
rate of convergence, and the obvious choice \((\mu)=1\) is not the
best. Some choices may even cause the multigrid method to fail
altogether. In practice it has been found that a value of the
same order as the other diagonal elements of the matrix is best,
and the following value has been found to work well in practice:

\[ \begin{align*}
(\mu) &= \min \left\{ \frac{2 + 2}{ij}, A \right\} , \\
(\mu) &= \min \left\{ \frac{h + h}{ij}, \{x, y\} \right\}.
\end{align*} \]

If the boundary conditions are either mixed or Neumann (i.e., \(B \neq 0\) on return from the user-supplied subroutine BNDY), then one
of the points in the seven-point stencil lies outside the domain.
In this case the normal derivative in the boundary conditions is
used to eliminate the 'fictitious' point, \(u\):

\[ \frac{dU}{dn} = \frac{1}{2h} (u_{\text{outside}} - u_{\text{inside}}). \]  (3)

It should be noted that if the boundary conditions are Neumann
and \((\phi)(x,y)=0\), then there is no unique solution. The routine
returns with IFAIL = 5 in this case, and the seven-diagonal
matrix is singular.

The four corners are treated separately. The user-supplied
subroutine BNDY is called twice, once along each of the edges
meeting at the corner. If both boundary conditions at this point
are Dirichlet and the prescribed solution values agree, then this
value is used in an equation of the form (2). If the prescribed
solution is discontinuous at the corner, then the average of the
two values is used. If one boundary condition is Dirichlet and
the other is mixed, then the value prescribed by the Dirichlet
condition is used in an equation of the form given above.
Finally, if both conditions are mixed or Neumann, then two 'fictitious' points are eliminated using two equations of the form (3).

It is possible that equations for which the solution is known at all points on the boundary, have coefficients which are not defined on the boundary. Since this routine calls the user-supplied subroutine PDEF at all points in the domain, including boundary points, arithmetic errors may occur in the user's routine PDEF which this routine cannot trap. If the user has an equation with Dirichlet boundary conditions (i.e., $B = 0$ at all points on the boundary), but with PDE coefficients which are singular on the boundary, then D03EDF could be called directly only using interior grid points with the user's own discretization.

After the equations have been set up as described above, they are checked for diagonal dominance. That is to say,

$$4 \quad \text{--} \quad k$$

$$|A_{ij}| > \frac{\sum_{j=1}^{n} |A_{ij}|}{n}$$

If this condition is not satisfied then the routine returns with IFAIL = 6. The multigrid routine D03EDF may still converge in this case, but if the coefficients of the first derivatives in the partial differential equation are large compared with the coefficients of the second derivative, the user should consider using upwind differences (SCHEME = 'U').

Since this routine is designed primarily for use with D03EDF, this document should be read in conjunction with the document for that routine.

4. References

5. Parameters

1: XMIN -- DOUBLE PRECISION Input

2: XMAX -- DOUBLE PRECISION Input

On entry: the lower and upper $x$ co-ordinates of the rectangular region respectively, $x_A$ and $x_B$. Constraint: $XMIN < XMAX$. 
3: YMIN -- DOUBLE PRECISION

4: YMAX -- DOUBLE PRECISION

On entry: the lower and upper y co-ordinates of the
rectangular region respectively, \( y_A \) and \( y_B \). Constraint: \( YMIN < YMAX \).

5: PDEF -- SUBROUTINE, supplied by the user.

External Procedure

PDEF must evaluate the functions \( (alpha)(x,y) \), \( (beta)(x,y) \),
\( (gamma)(x,y) \), \( (delta)(x,y) \), \( (epsilon)(x,y) \), \( (phi)(x,y) \) and
\( (psi)(x,y) \) which define the equation at a general point
\( (x,y) \).

Its specification is:

```plaintext
SUBROUTINE PDEF (X, Y, ALPHA, BETA, GAMMA,
1  DELTA, EPSLON, PHI, PSI)
  DOUBLE PRECISION X, Y, ALPHA, BETA, GAMMA, DELTA,
1  EPSLON, PHI, PSI
```

1: X -- DOUBLE PRECISION

2: Y -- DOUBLE PRECISION

On entry: the x and y co-ordinates of the point at
which the coefficients of the partial differential
equation are to be evaluated.

3: ALPHA -- DOUBLE PRECISION

4: BETA -- DOUBLE PRECISION

5: GAMMA -- DOUBLE PRECISION

6: DELTA -- DOUBLE PRECISION

7: EPSLON -- DOUBLE PRECISION

8: PHI -- DOUBLE PRECISION

9: PSI -- DOUBLE PRECISION

On exit: ALPHA, BETA, GAMMA, DELTA, EPSLON, PHI and PSI
must be set to the values of \( (alpha)(x,y) \), \( (beta)(x,y) \),
\( (gamma)(x,y) \), \( (delta)(x,y) \), \( (epsilon)(x,y) \), \( (phi)(x,y) \)
and \( (psi)(x,y) \) respectively at the point specified by \( X \)
and \( Y \).

PDEF must be declared as EXTERNAL in the (sub)program
from which D03EEF is called. Parameters denoted as
Input must not be changed by this procedure.

6: **BNDY -- SUBROUTINE**, supplied by the user.

External Procedure

**BNDY** must evaluate the functions \( a(x,y) \), \( b(x,y) \), and \( c(x,y) \) involved in the boundary conditions.

Its specification is:

```fortran
SUBROUTINE BNDY (X, Y, A, B, C, IBND)
INTEGER IBND
DOUBLE PRECISION X, Y, A, B, C
```

1: **X -- DOUBLE PRECISION**  
   Input

2: **Y -- DOUBLE PRECISION**  
   Input
   On entry: the \( x \) and \( y \) co-ordinates of the point at which the boundary conditions are to be evaluated.

3: **A -- DOUBLE PRECISION**  
   Output

4: **B -- DOUBLE PRECISION**  
   Output

5: **C -- DOUBLE PRECISION**  
   Output
   On exit: \( A \), \( B \) and \( C \) must be set to the values of the functions appearing in the boundary conditions.

6: **IBND -- INTEGER**  
   Input
   On entry: specifies on which boundary the point \((X,Y)\) lies. \( IBND = 0 \), 1, 2 or 3 according as the point lies on the bottom, right, top or left boundary.

**BNDY** must be declared as **EXTERNAL** in the (sub)program from which **D03EEF** is called. Parameters denoted as Input must not be changed by this procedure.

7: **NGX -- INTEGER**  
   Input

8: **NGY -- INTEGER**  
   Input
   On entry: the number of interior grid points in the \( x \)- and \( y \)-directions respectively, \( n \) and \( n' \). If the seven-diagonal equations are to be solved by **D03EDF**, then \( NGX - 1 \) and \( NGY - 1 \) should preferably be divisible by as high a power of 2 as possible. Constraint: \( NGX >= 3, NGY >= 3 \).

9: **LDA -- INTEGER**  
   Input
   On entry: the first dimension of the array \( A \) as declared in the (sub)program from which **D03EEF** is called.
   Constraint: if only the seven-diagonal equations are
required, then LDA >= NGX*NGY. If a call to this routine is
to be followed by a call to D03EDF to solve the seven-
diagonal linear equations, LDA >= (4*(NGX+1)*(NGY+1))/3.

Note: this routine only checks the former condition. D03EDF,
if called, will check the latter condition.

10: A(LDA,7) -- DOUBLE PRECISION array Output
On exit: A(i,j), for i=1,2,...,NGX*NGY; j = 1,2,...,7,
contains the seven-diagonal linear equations produced by the
discretization described above. If LDA > NGX*NGY, the
remaining elements are not referenced by the routine, but if
LDA >= (4*(NGX+1)*(NGY+1))/3 then the array A can be passed
directly to D03EDF, where these elements are used as
workspace.

11: RHS(LDA) -- DOUBLE PRECISION array Output
On exit: the first NGX*NGY elements contain the right-hand
sides of the seven-diagonal linear equations produced by the
discretization described above. If LDA > NGX*NGY, the
remaining elements are not referenced by the routine, but if
LDA >= (4*(NGY+1)*(NGY+1))/3 then the array RHS can be
passed directly to D03EDF, where these elements are used as
workspace.

12: SCHEME -- CHARACTER*1 Input
On entry: the type of approximation to be used for the first
derivatives which occur in the partial differential
equation.

If SCHEME = 'C', then central differences are used.

If SCHEME = 'U', then upwind differences are used.
Constraint: SCHEME = 'C' or 'U'.

Note: generally speaking, if at least one of the
coefficients multiplying the first derivatives (DELTA or
EPSLON as returned by PDEF) are large compared with the
coefficients multiplying the second derivatives, then upwind
differences may be more appropriate. Upwind differences are
less accurate than central differences, but may result in
more rapid convergence for strongly convective equations.
The easiest test is to try both schemes.

13: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. Users who are
unfamiliar with this parameter should refer to the Essential
Introduction for details.

On exit: IFAIL = 0 unless the routine detects an error or
gives a warning (see Section 6).

For this routine, because the values of output parameters may be useful even if IFAIL /=0 on exit, users are recommended to set IFAIL to -1 before entry. It is then essential to test the value of IFAIL on exit.

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

**IFAIL= 1**

On entry XMIN >= XMAX,

or YMIN >= YMAX,

or NGX < 3,

or NGY < 3,

or LDA < NGX*NGY,

or SCHEME is not one of 'C' or 'U'.

**IFAIL= 2**

At some point on the boundary there is a derivative in the boundary conditions (B /= 0 on return from a BNDY) and there is a non-zero coefficient of the mixed derivative (BETA /= 0 on return from PDEF).

**IFAIL= 3**

A null boundary has been specified, i.e., at some point both A and B are zero on return from a call to BNDY.

**IFAIL= 4**

The equation is not elliptic, i.e., 4*ALPHA*GAMMA<BETA after a call to PDEF. The discretization has been completed, but the convergence of D03EDF cannot be guaranteed.

**IFAIL= 5**

The boundary conditions are purely Neumann (only the derivative is specified) and there is, in general, no unique solution.
IFAIL = 6
The equations were not diagonally dominant. (See Section 3).

7. Accuracy
Not applicable.

8. Further Comments
If this routine is used as a pre-processor to the multigrid routine D03EDF it should be noted that the rate of convergence of that routine is strongly dependent upon the number of levels in the multigrid scheme, and thus the choice of NGX and NGY is very important.

9. Example
The program solves the elliptic partial differential equation

\[
\begin{align*}
\frac{\partial^2 U}{\partial x^2} + \frac{\partial^2 U}{\partial y^2} + 50 \left( \frac{\partial U}{\partial x} + \frac{\partial U}{\partial y} \right) &= f(x, y) \\
\end{align*}
\]

on the unit square \(0 \leq x, y \leq 1\), with boundary conditions

\[
\begin{align*}
\frac{\partial U}{\partial n} & \quad \text{given on } x=0 \text{ and } y=0, \\
U & \quad \text{given on } x=1 \text{ and } y=1.
\end{align*}
\]

The function \(f(x, y)\) and the exact form of the boundary conditions are derived from the exact solution \(U(x, y) = \sin x \sin y\).

The equation is first solved using central differences. Since the coefficients of the first derivatives are large, the linear equations are not diagonally dominated, and convergence is slow. The equation is solved a second time with upwind differences, showing that convergence is more rapid, but the solution is less accurate.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

Helmholtz equation in 3 dimensions

--- nagd.ht ---

D03FAF(3NAG)  Foundation Library (12/10/92)  D03FAF(3NAG)

D03 -- Partial Differential Equations  D03FAF
   D03FAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

   D03FAF solves the Helmholtz equation in Cartesian co-ordinates in three dimensions using the standard seven-point finite difference approximation. This routine is designed to be particularly efficient on vector processors.

2. Specification

   SUBROUTINE D03FAF (XS, XF, L, LBDCND, BDXS, BDXF, YS, YF,
   1  M, MBDCND, BDYS, BDYF, ZS, ZF, N,
   2  NBDCND, BDZS, BDZF, LAMBDA, LDIMF,
   3  MDIMF, F, PERTRB, W, LWRK, IFAIL)
   INTEGER  L, LBDCND, M, MBDCND, N, NBDCND, LDIMF,
   1  MDIMF, LWRK, IFAIL
   DOUBLE PRECISION  XS, XF, BDXS(MDIMF,N+1), BDXF(MDIMF,N+1),
   1  YS, YF, BDYS(LDIMF,N+1), BDYF(LDIMF,N+1),
   2  ZS, ZF, BDZS(LDIMF,M+1), BDZF(LDIMF,M+1),
   3  LAMBDA, F(LDIMF,MDIMF,N+1), PERTRB, W
   4  (LWRK)
3. Description

D03FAF solves the three-dimensional Helmholtz equation in cartesian co-ordinates:

\[
\begin{array}{ccc}
\dd u & \dd u & \dd u \\
\dd x & \dd y & \dd z \\
\end{array}
\frac{1}{\lambda} u = f(x,y,z)
\]

This subroutine forms the system of linear equations resulting from the standard seven-point finite difference equations, and then solves the system using a method based on the fast Fourier transform (FFT) described by Swarztrauber [1]. This subroutine is based on the routine HW3CRT from FISHPACK (see Swarztrauber and Sweet [2]).

More precisely, the routine replaces all the second derivatives by second-order central difference approximations, resulting in a block tridiagonal system of linear equations. The equations are modified to allow for the prescribed boundary conditions. Either the solution or the derivative of the solution may be specified on any of the boundaries, or the solution may be specified to be periodic in any of the three dimensions. By taking the discrete Fourier transform in the x- and y-directions, the equations are reduced to sets of tridiagonal systems of equations. The Fourier transforms required are computed using the multiple FFT routines found in Chapter C06 of the NAG Fortran Library.

4. References

5. Parameters

1: XS -- DOUBLE PRECISION
   On entry: the lower bound of the range of x, i.e., XS <= x <= XF. Constraint: XS < XF.
2: XF -- DOUBLE PRECISION
   On entry: the upper bound of the range of x, i.e., XS <= x <= XF. Constraint: XS < XF.
3: L -- INTEGER
   Input
   On entry: the number of panels into which the interval
   \((X_S, X_F)\) is subdivided. Hence, there will be \(L+1\) grid points
   in the \(x\)-direction given by \(x = X_S + (i-1) \ast (\text{delta}x)\), for
   \(i = 1, 2, \ldots, L+1\), where \((\text{delta}x) = (X_F - X_S) / L\) is the panel width.
   Constraint: \(L \geq 5\).

4: LBDCND -- INTEGER
   Input
   On entry: indicates the type of boundary conditions at \(x = X_S\) and \(x = X_F\).
   LBDCND = 0
   if the solution is periodic in \(x\), i.e.,
   \(u(X_S, y, z) = u(X_F, y, z)\).
   LBDCND = 1
   if the solution is specified at \(x = X_S\) and \(x = X_F\).
   LBDCND = 2
   if the solution is specified at \(x = X_S\) and the
   derivative of the solution with respect to \(x\) is
   specified at \(x = X_F\).
   LBDCND = 3
   if the derivative of the solution with respect to \(x\) is
   specified at \(x = X_S\) and \(x = X_F\).
   LBDCND = 4
   if the derivative of the solution with respect to \(x\) is
   specified at \(x = X_S\) and the solution is specified at \(x = X_F\).
   Constraint: \(0 \leq LBDCND \leq 4\).

5: BDXS(MDIMF,N+1) -- DOUBLE PRECISION array
   Input
   On entry: the values of the derivative of the solution with
   respect to \(x\) at \(x = X_S\). When LBDCND = 3 or 4, BDXS
   \((j,k) = u(X_S, y, z)\), for \(j=1,2,\ldots,N+1; k=1,2,\ldots,N+1\).
   \(x j k\)
   When LBDCND has any other value, BDXS is not referenced.

6: BDXF(MDIMF,N+1) -- DOUBLE PRECISION array
   Input
   On entry: the values of the derivative of the solution with
   respect to \(x\) at \(x = X_F\). When LBDCND = 2 or 3, BDXF\((j,k) = u(X_F, y, z)\), for \(j=1,2,\ldots,N+1; k=1,2,\ldots,N+1\).
   \(x i k\)
   When LBDCND has any other value, BDXF is not referenced.

7: YS -- DOUBLE PRECISION
   Input
On entry: the lower bound of the range of \( y \), i.e., \( YS \leq y \leq YF \). Constraint: \( YS < YF \).

8: \( YF \) -- DOUBLE PRECISION Input
On entry: the upper bound of the range of \( y \), i.e., \( YS \leq y \leq YF \). Constraint: \( YS < YF \).

9: \( M \) -- INTEGER Input
On entry: the number of panels into which the interval \((YS,YF)\) is subdivided. Hence, there will be \( M+1 \) grid points in the \( y \)-direction given by \( y = YS + (j-1) \times (\text{delta})y \) for \( j = 1, 2, \ldots, M+1 \), where \( (\text{delta})y = (YF - YS) / M \) is the panel width. Constraint: \( M \geq 5 \).

10: \( MBDCND \) -- INTEGER Input
On entry: indicates the type of boundary conditions at \( y = YS \) and \( y = YF \).
\( MBDCND = 0 \) if the solution is periodic in \( y \), i.e., \( u(x,YF,z) = u(x,YS,z) \).
\( MBDCND = 1 \) if the solution is specified at \( y = YS \) and \( y = YF \).
\( MBDCND = 2 \) if the solution is specified at \( y = YS \) and the derivative of the solution with respect to \( y \) is specified at \( y = YF \).
\( MBDCND = 3 \) if the derivative of the solution with respect to \( y \) is specified at \( y = YS \) and \( y = YF \).
\( MBDCND = 4 \) if the derivative of the solution with respect to \( y \) is specified at \( y = YS \) and the solution is specified at \( y = YF \). Constraint: \( 0 \leq MBDCND \leq 4 \).

11: \( BDYS(LDIMF,N+1) \) -- DOUBLE PRECISION array Input
On entry: the values of the derivative of the solution with respect to \( y \) at \( y = YS \). When \( MBDCND = 3 \) or \( 4 \), \( BDYS(i,k) = u(x,y,z) \), for \( i = 1, 2, \ldots, L+1 \); \( k = 1, 2, \ldots, N+1 \).
\( y \) is \( k \)

When \( MBDCND \) has any other value, \( BDYS \) is not referenced.

12: \( BDYF(LDIMF,N+1) \) -- DOUBLE PRECISION array Input
On entry: the values of the derivative of the solution with
respect to \( y \) at \( y = YF \). When \( MBDCND = 2 \) or \( 3 \), \( BDYF \)
\[(i,k) = u(x_i,yF,z_k), \text{ for } i=1,2,...,L+1; \ k=1,2,...,N+1.\]

When \( MBDCND \) has any other value, \( BDYF \) is not referenced.

13: \( ZS \) -- DOUBLE PRECISION Input
On entry: the lower bound of the range of \( z \), i.e., \( ZS \leq z \leq ZF \). Constraint: \( ZS < ZF \).

14: \( ZF \) -- DOUBLE PRECISION Input
On entry: the upper bound of the range of \( z \), i.e., \( ZS \leq z \leq ZF \). Constraint: \( ZS < ZF \).

15: \( N \) -- INTEGER Input
On entry: the number of panels into which the interval \((ZS,ZF)\) is subdivided. Hence, there will be \( N+1 \) grid points in the \( z \)-direction given by \( z = ZS + (k-1)*(\delta z) \), for \( k \)
\( k=1,2,...,N+1 \), where \( (\delta z) = (ZF-ZS)/N \) is the panel width. Constraint: \( N \geq 5 \).

16: \( NBDCND \) -- INTEGER Input
On entry: specifies the type of boundary conditions at \( z = ZS \) and \( z = ZF \).
\( NBDCND = 0 \)
if the solution is periodic in \( z \), i.e.,
\( u(x,y,ZF) = u(x,y,ZS) \).

\( NBDCND = 1 \)
if the solution is specified at \( z = ZS \) and \( z = ZF \).

\( NBDCND = 2 \)
if the solution is specified at \( z = ZS \) and the derivative of the solution with respect to \( z \) is specified at \( z = ZF \).

\( NBDCND = 3 \)
if the derivative of the solution with respect to \( z \) is specified at \( z = ZS \) and \( z = ZF \).

\( NBDCND = 4 \)
if the derivative of the solution with respect to \( z \) is specified at \( z = ZS \) and the solution is specified at \( z = ZF \).
Constraint: \( 0 \leq NBDCND \leq 4 \).

17: \( BDZS(LDIMF,M+1) \) -- DOUBLE PRECISION array Input
On entry: the values of the derivative of the solution with respect to \( z \) at \( z = ZS \). When \( NBDCND = 3 \) or \( 4 \), \( BDZS \)
(i,j)=u(x,y,zS)=u(x,y,z), for i=1,2,...,L+1;
  j=1,2,...,M+1.

When NBDCND has any other value, BDZS is not referenced.

18: BDZF(LDIMF,M+1) -- DOUBLE PRECISION array Input
On entry: the values of the derivative of the solution with respect to z at z = ZF. When NBDCND = 2 or 3, BDZF
(i,j)=u(x,y,ZF)=u(x,y,z), for i=1,2,...,L+1;
  j=1,2,...,M+1.

When NBDCND has any other value, BDZF is not referenced.

19: LAMBDA -- DOUBLE PRECISION Input
On entry: the constant (lambda) in the Helmholtz equation.
For certain positive values of (lambda) a solution to the differential equation may not exist, and close to these values the solution of the discretized problem will be extremely ill-conditioned. If (lambda)>0, then D03FAF will set IFAIL to 3, but will still attempt to find a solution. However, since in general the values of (lambda) for which no solution exists cannot be predicted a priori, the user is advised to treat any results computed with (lambda)>0 with great caution.

20: LDIMF -- INTEGER Input
On entry: the first dimension of the arrays F, BDYS, BDYF, BDZS and BDZF as declared in the (sub)program from which D03FAF is called.
Constraint: LDIMF >= L + 1.

21: MDIMF -- INTEGER Input
On entry: the second dimension of the array F and the first dimension of the arrays BDXS and BDXF as declared in the (sub)program from which D03FAF is called.
Constraint: MDIMF >= M + 1.

22: F(LDIMF,MDIMF,N+1) -- DOUBLE PRECISION array Input/Output
On entry: the values of the right-side of the Helmholtz equation and boundary values (if any).
F(i,j,k)=f(x,y,z) i=2,3,...,L, j=2,3,...,M and k
  i j k
=2,3,...,N.

On the boundaries F is defined by
LBDCND F(1,j,k) F(L+1,j,k)
CHAPTER 22. NAG LIBRARY ROUTINES

0 \begin{align*}
& f(XS, y, z) f(XS, y, z) \\
& j \ k \ j \ k
\end{align*}

1 \begin{align*}
& u(XS, y, z) u(XF, y, z) \\
& j \ k \ j \ k
\end{align*}

2 \begin{align*}

& i \ k \ i \ k
\end{align*}

4 \begin{align*}
& f(x, YS, z) u(x, YF, z) \\
& i \ k \ i \ k
\end{align*}

\text{NBDCND} \quad F(i, j) \quad F(i, j, N+1)

0 \begin{align*}
& f(x, y, ZS) f(x, y, ZS) \\
& i \ j \ i \ j
\end{align*}

1 \begin{align*}
& u(x, y, ZS) u(x, y, ZF) \\
& i \ j \ i \ j
\end{align*}

2 \begin{align*}
& u(x, y, ZS) f(x, y, ZF) \quad i=1,2,\ldots,L+1 \\
& i \ j \ i \ j
\end{align*}
3 \( f(x_i, y_j, z_k) f(x_i, y_j, z_k) \quad j=1,2,...,M+1 \)
4 \( f(x_i, y_j, z_k) u(x_i, y_j, z_k) \)

Note: if the table calls for both the solution \( u \) and the right-hand side \( f \) on a boundary, then the solution must be specified. On exit: \( F \) contains the solution \( u(i,j,k) \) of the finite difference approximation for the grid point \((x_i, y_j, z_k)\) for \( i=1,2,...,L+1 \), \( j=1,2,...,M+1 \) and \( k=1,2,...,N+1 \).

23: `PERTRB` -- DOUBLE PRECISION Output
On exit: `PERTRB = 0`, unless a solution to Poisson's equation ((\( \lambda \))=0) is required with a combination of periodic or derivative boundary conditions (\( LBDCND \), \( MBDCND \) and \( NBDCND = 0 \) or 3). In this case a solution may not exist. `PERTRB` is a constant, calculated and subtracted from the array \( F \), which ensures that a solution exists. D03FAF then computes this solution, which is a least-squares solution to the original approximation. This solution is not unique and is unnormalised. The value of `PERTRB` should be small compared to the right-hand side \( F \), otherwise a solution has been obtained to an essentially different problem. This comparison should always be made to insure that a meaningful solution has been obtained.

24: \( W(LWRK) \) -- DOUBLE PRECISION array Workspace
25: `LWRK` -- INTEGER Input
On entry: the dimension of the array \( W \) as declared in the (sub)program from which D03FAF is called.
\( LRWK \geq 2*(N+1)*\max(L,M)+3*L+3*M+4*N+6 \) is an upper bound on the required size of \( W \). If `LWRK` is too small, the routine exits with \( IFAIL = 2 \), and if on entry \( IFAIL = 0 \) or \( IFAIL = -1 \), a message is output giving the exact value of \( LRWK \) required to solve the current problem.

26: `IFAIL` -- INTEGER Input/Output
On entry: `IFAIL` must be set to 0, -1 or 1. Users who are unfamiliar with this parameter should refer to the Essential Introduction for details.

On exit: `IFAIL = 0` unless the routine detects an error or gives a warning (see Section 6).

For this routine, because the values of output parameters may be useful even if `IFAIL /= 0` on exit, users are recommended to set `IFAIL` to -1 before entry. It is then
essential to test the value of IFAIL on exit.

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1
On entry XS >= XF,
 or L < 5,
 or LBDCND < 0,
 or LBDCND > 4,
 or YS >= YF,
 or M < 5,
 or MBDCND < 0,
 or MBDCND > 4,
 or ZS >= ZF,
 or N < 5,
 or NBDCND < 0,
 or NBDCND > 4,
 or LDIMF < L + 1 > 0,
 or MDIMF < M + 1.

IFAIL= 2
On entry LWRK is too small.

IFAIL= 3
On entry (lambda) > 0.

7. Accuracy

None.

8. Further Comments
The execution time is roughly proportional to 
$L^2 M^2 N^2 (\log L + \log M + 5)$, but also depends on input parameters 
$L_{BDCND}$ and $M_{BDCND}$.

9. Example

The example solves the Helmholtz equation

\[
\begin{align*}
\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} + \frac{\partial^2 u}{\partial z^2} + \lambda u &= f(x, y, z) \\
(\pi) &
\end{align*}
\]

for $(x, y, z) \in [0, 1] \times [0, 2\pi] \times [0, \pi]$ where $\lambda = -2$, and 
$f(x, y, z)$ is derived from the exact solution

\[
u(x, y, z) = x \sin(y) \cos(z).\]

The equation is subject to the following boundary conditions, 
again derived from the exact solution given above.

- $u(0, y, z)$ and $u(1, y, z)$ are prescribed (i.e., $L_{BDCND} = 1$).
- $u(x, 0, z) = u(x, 2\pi, z)$ (i.e., $M_{BDCND} = 0$).
- $u(x, y, 0)$ and $u(x, y, \pi)$ are prescribed (i.e., $N_{BDCND} = 2$).

The example program is not reproduced here. The source code for 
all example programs is distributed with the NAG Foundation 
Library software and should be available on-line.

E01 -- Interpolation
Introduction -- E01

Chapter E01
Interpolation

1. Scope of the Chapter

This chapter is concerned with the interpolation of a function of one or two variables. When provided with the value of the function (and possibly one or more of its lowest-order derivatives) at each of a number of values of the variable(s), the routines provide either an interpolating function or an interpolated value. For some of the interpolating functions, there are supporting routines to evaluate, differentiate or integrate them.

2. Background to the Problems

In motivation and in some of its numerical processes, this chapter has much in common with Chapter E02 (Curve and Surface Fitting). For this reason, we shall adopt the same terminology and refer to dependent variable and independent variable(s) instead of function and variable(s). Where there is only one independent variable, we shall denote it by $x$ and the dependent variable by $y$. Thus, in the basic problem considered in this chapter, we are given a set of distinct values $x_1, x_2, \ldots, x_m$ and a corresponding set of values $y_1, y_2, \ldots, y_m$ of $y$. Thus, in the basic problem considered in this chapter, we are given a set of distinct values $x_1, x_2, \ldots, x_m$ and a corresponding set of values $y_1, y_2, \ldots, y_m$ of $y$, and we shall describe the problem as being one of interpolating the data points $(x_r, y_r)$, rather than interpolating a function. In modern usage, however, interpolation can have either of two rather
different meanings, both relevant to routines in this chapter. They are

(a) the determination of a function of \( x \) which takes the value \( y_r \) at \( x=x_r \), for \( r=1,2,...,m \) (an interpolating function or interpolant),

(b) the determination of the value (interpolated value or interpolate) of an interpolating function at any given value, say \( x \), of \( x \) within the range of the \( x \) (so as to estimate the value at \( x \) of the function underlying the data).

The latter is the older meaning, associated particularly with the use of mathematical tables. The term 'function underlying the data', like the other terminology described above, is used so as to cover situations additional to those in which the data points have been computed from a known function, as with a mathematical table. In some contexts, the function may be unknown, perhaps representing the dependency of one physical variable on another, say temperature upon time.

Whether the underlying function is known or unknown, the object of interpolation will usually be to approximate it to acceptable accuracy by a function which is easy to evaluate anywhere in some range of interest. Piecewise polynomials such as cubic splines (see Section 2.2 of the E02 Chapter Introduction for definitions of terms in this case), being easy to evaluate and also capable of approximating a wide variety of functions, are the types of function mostly used in this chapter as interpolating functions.

Piecewise polynomials also, to a large extent, avoid the well-known problem of large unwanted fluctuations which can arise when interpolating a data set with a simple polynomial. Fluctuations can still arise but much less frequently and much less severely than with simple polynomials. Unwanted fluctuations are avoided altogether by a routine using piecewise cubic polynomials having only first derivative continuity. It is designed especially for monotonic data, but for other data still provides an interpolant which increases, or decreases, over the same intervals as the data.

The concept of interpolation can be generalised in a number of ways. For example, we may be required to estimate the value of the underlying function at a value \( x \) outside the range of the
data. This is the process of extrapolation. In general, it is a
good deal less accurate than interpolation and is to be avoided
whenever possible.

Interpolation can also be extended to the case of two independent
variables. We shall denote these by \( x \) and \( y \), and the dependent
variable by \( f \). Methods used depend markedly on whether or not the
data values of \( f \) are given at the intersections of a rectangular
mesh in the \((x,y)\)-plane. If they are, bicubic splines (see
Section 2.3.2 of the E02 Chapter Introduction) are very suitable
and usually very effective for the problem. For other cases,
perhaps where the \( f \) values are quite arbitrarily scattered in the
\((x,y)\)-plane, polynomials and splines are not at all appropriate
and special forms of interpolating function have to be employed.
Many such forms have been devised and two of the most successful
are in routines in this chapter. They both have continuity in
first, but not higher, derivatives.

Addison-Wesley (2nd Edition).

Hall.

3. Recommendations on Choice and Use of Routines

3.1. General

Before undertaking interpolation, in other than the simplest
cases, the user should seriously consider the alternative of
using a routine from Chapter E02 to approximate the data by a
polynomial or spline containing significantly fewer coefficients
than the corresponding interpolating function. This approach is
much less liable to produce unwanted fluctuations and so can
often provide a better approximation to the function underlying
the data.

When interpolation is employed to approximate either an
underlying function or its values, the user will need to be
satisfied that the accuracy of approximation achieved is
adequate. There may be a means for doing this which is particular
to the application, or the routine used may itself provide a
means. In other cases, one possibility is to repeat the
interpolation using one or more extra data points, if they are
available, or otherwise one or more fewer, and to compare the
results. Other possibilities, if it is an interpolating function
which is determined, are to examine the function graphically, if
that gives sufficient accuracy, or to observe the behaviour of
the differences in a finite-difference table, formed from evaluations of the interpolating function at equally-spaced values of $x$ over the range of interest. The spacing should be small enough to cause the typical size of the differences to decrease as the order of difference increases.

3.2. One Independent Variable

$E01BAF$ computes an interpolating cubic spline, using a particular choice for the set of knots which has proved generally satisfactory in practice. If the user wishes to choose a different set, a cubic spline routine from Chapter $E02$, namely $E02BAF$, may be used in its interpolating mode, setting $NCAP7 = M+4$ and all elements of the parameter $W$ to unity. These routines provide the interpolating function in $B$-spline form (see Section 2.2.2 in the $E02$ Chapter Introduction). Routines for evaluating, differentiating and integrating this form are discussed in Section 3.7 of the $E02$ Chapter Introduction.

The cubic spline does not always avoid unwanted fluctuations, especially when the data show a steep slope close to a region of small slope, or when the data inadequately represent the underlying curve. In such cases, $E01BEF$ can be very useful. It derives a piecewise cubic polynomial (with first derivative continuity) which, between any adjacent pair of data points, either increases all the way, or decreases all the way (or stays constant). It is especially suited to data which are monotonic over their whole range.

In this routine, the interpolating function is represented simply by its value and first derivative at the data points. Supporting routines compute its value and first derivative elsewhere, as well as its definite integral over an arbitrary interval.

3.3. Two Independent Variables

3.3.1. Data on a rectangular mesh

Given the value $f$ of the dependent variable $f$ at the point $(x_q,y_r)$ in the plane of the independent variables $x$ and $y$, for $q=1,2,...,m$ and $r=1,2,...,n$ (so that the points $(x_q,y_r)$ lie at the $m\times n$ intersections of a rectangular mesh), $E01DAF$ computes an interpolating bicubic spline, using a particular choice for each of the spline's knot-set. This choice, the same as in $E01BAF$, has proved generally satisfactory in practice. If, instead, the user wishes to specify his own knots, a routine from Chapter $E02$, namely $E02DAF$, may be adapted (it is more cumbersome for the
purpose, however, and much slower for larger problems). Using \( m \) and \( n \) in the above sense, the parameter \( M \) must be set to \( m+n \), \( PX \) and \( PY \) must be set to \( m+4 \) and \( n+4 \) respectively and all elements of \( W \) should be set to unity. The recommended value for \( EPS \) is zero.

3.3.2. Arbitrary data

As remarked at the end of Section 2, special types of interpolating are required for this problem, which can often be difficult to solve satisfactorily. Two of the most successful are employed in E01SAF and E01SEF, the two routines which (with their respective evaluation routines E01SBF and E01SFF) are provided for the problem. Definitions can be found in the routine documents. Both interpolants have first derivative continuity and are 'local', in that their value at any point depends only on data in the immediate neighbourhood of the point. This latter feature is necessary for large sets of data to avoid prohibitive computing time.

The relative merits of the two methods vary with the data and it is not possible to predict which will be the better in any particular case.

Cubic spline interpolant

— nage.ht —

\begin{page}{manpageXXe01baf}{NAG Documentation: e01baf}
\beginscroll
\begin{verbatim}
1. Purpose

E01BAF determines a cubic spline interpolant to a given set of data.

2. Specification

```plaintext
SUBROUTINE E01BAF (M, X, Y, LAMDA, C, LCK, WRK, LWRK, IFAIL)
INTEGER M, LCK, LWRK, IFAIL
DOUBLE PRECISION X(M), Y(M), LAMDA(LCK), C(LCK), WRK(LWRK)
```

3. Description

This routine determines a cubic spline $s(x)$, defined in the range $1 \leq x \leq m$, which interpolates (passes exactly through) the set of $m$ data points $(x_i, y_i)$, for $i=1,2,...,m$, where $m \geq 4$ and $x_1 < x_2 < ... < x_m$ end conditions are not imposed. The spline interpolant chosen has $m-4$ interior knots $(\lambda_5, \lambda_6, ..., \lambda_m)$, which are set to the values of $x_3, x_4, ..., x_{m-2}$ respectively. This spline is represented in its B-spline form (see Cox [1]):

$$
\sum_{i=1}^{m} c_i N_i(x),
$$

where $N_i(x)$ denotes the normalised B-Spline of degree 3, defined upon the knots $(\lambda_5, \lambda_6, ..., \lambda_m)$, and $c_i$...
denotes its coefficient, whose value is to be determined by the routine.

The use of B-splines requires eight additional knots (\(\lambda\)), 
\[
\begin{array}{cccccc}
1 \\
2 & 3 & 4 \\
m+1 & m+2 \\
m+3 & m+4 \\
\end{array}
\]
to be specified; the routine sets the first four of these to \(x\) and the last four to \(x\).

The algorithm for determining the coefficients is as described in [1] except that QR factorization is used instead of LU decomposition. The implementation of the algorithm involves setting up appropriate information for the related routine E02BAF followed by a call of that routine. (For further details of E02BAF, see the routine document.)

Values of the spline interpolant, or of its derivatives or definite integral, can subsequently be computed as detailed in Section 8.

4. References

5. Parameters

1: \textbf{M} -- INTEGER Input
   On entry: \(m\), the number of data points. Constraint: \(M \geq 4\).

2: \textbf{X(M)} -- DOUBLE PRECISION array Input
   On entry: \(X(i)\) must be set to \(x\), the \(i\)th data value of the independent variable \(x\), for \(i=1,2,...,m\). Constraint: \(X(i) < X(i+1), \text{ for } i=1,2,...,M-1\).

3: \textbf{Y(M)} -- DOUBLE PRECISION array Input
   On entry: \(Y(i)\) must be set to \(y\), the \(i\)th data value of the dependent variable \(y\), for \(i=1,2,...,m\).

4: \textbf{LAMDA(LCK)} -- DOUBLE PRECISION array Output
On exit: the value of \((\lambda_i)\), the \(i\)th knot, for \(i=1,2,\ldots,m+4\).

5: \(C(LCK)\) -- DOUBLE PRECISION array
   On exit: the coefficient \(c_i\) of the B-spline \(N(x)\), for \(i=1,2,\ldots,m\). The remaining elements of the array are not used.

6: \(LCK\) -- INTEGER Input
   On entry:
   the dimension of the arrays \(LAMDA\) and \(C\) as declared in the
   (sub)program from which E01BAF is called.
   Constraint: \(LCK \geq M + 4\).

7: \(WRK(LWRK)\) -- DOUBLE PRECISION array Workspace

8: \(LWRK\) -- INTEGER Input
   On entry:
   the dimension of the array \(WRK\) as declared in the
   (sub)program from which E01BAF is called.
   Constraint: \(LWRK \geq 6*M+16\).

9: \(IFAIL\) -- INTEGER Input/Output
   On entry: \(IFAIL\) must be set to 0, -1 or 1. For users not
   familiar with this parameter (described in the Essential
   Introduction) the recommended value is 0.
   On exit: \(IFAIL = 0\) unless the routine detects an error (see
   Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

\(IFAIL = 1\)
On entry \(M < 4\),
or \(LCK < M+4\),
or \(LWRK < 6*M+16\).

\(IFAIL = 2\)
The \(X\)-values fail to satisfy the condition
\[X(1) < X(2) < X(3) < \ldots < X(M)\].

7. Accuracy
The rounding errors incurred are such that the computed spline is an exact interpolant for a slightly perturbed set of ordinates \( y_i + \delta y_i \). The ratio of the root-mean-square value of the \( \delta y_i \) to that of the \( y_i \) is no greater than a small multiple of the relative machine precision.

8. Further Comments

The time taken by the routine is approximately proportional to \( m \).

All the \( x_i \) are used as knot positions except \( x_1 \) and \( x_{m-1} \). This choice of knots (see Cox [2]) means that \( s(x) \) is composed of \( m-3 \) cubic arcs as follows. If \( m=4 \), there is just a single arc spanning the whole interval \( x_1 \) to \( x_4 \). If \( m \geq 5 \), the first and last arcs span the intervals \( x_1 \) to \( x_3 \) and \( x_4 \) to \( x_m \) respectively. Additionally if \( m \geq 6 \), the \( i \)th arc, for \( i=2,3,\ldots,m-4 \) spans the interval \( x_i \) to \( x_{i+2} \).

After the call

\[
\text{CALL E01BAF (M, X, Y, LAMDA, C, LCK, WRK, LWRK, IFAIL)}
\]

the following operations may be carried out on the interpolant \( s(x) \).

The value of \( s(x) \) at \( x = XVAL \) can be provided in the real variable \( SVAL \) by the call

\[
\text{CALL E02BBF (M+4, LAMDA, C, XVAL, SVAL, IFAIL)}
\]

The values of \( s(x) \) and its first three derivatives at \( x = XVAL \) can be provided in the real array \( SDIF \) of dimension 4, by the call

\[
\text{CALL E02BCF (M+4, LAMDA, C, XVAL, LEFT, SDIF, IFAIL)}
\]

Here \( LEFT \) must specify whether the left- or right-hand value of the third derivative is required (see \text{E02BCF} for details).

The value of the integral of \( s(x) \) over the range \( x_1 \) to \( x_m \) can be provided in the real variable \( SINT \) by

\[
\text{CALL E02BDF (M+4, LAMDA, C, SINT, IFAIL)}
\]
9. Example

The example program sets up data from 7 values of the exponential function in the interval 0 to 1. E01BAF is then called to compute a spline interpolant to these data.

The spline is evaluated by E02BBF, at the data points and at points halfway between each adjacent pair of data points, and the \( x \) spline values and the values of \( e \) are printed out.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

——

Monotonicity-preserving piecewise cubic Hermite interpolant

—— nage.ht ——

E01BEF(3NAG) Foundation Library (12/10/92) E01BEF(3NAG)

E01 -- Interpolation  E01BEF
E01BEF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E01BEF computes a monotonicity-preserving piecewise cubic Hermite
interpolant to a set of data points.

2. Specification

```plaintext
SUBROUTINE E01BEF (N, X, F, D, IFAIL)
INTEGER       N, IFAIL
DOUBLE PRECISION X(N), F(N), D(N)
```

3. Description

This routine estimates first derivatives at the set of data points \((x_r, f_r)\), for \(r=1,2,\ldots,n\), which determine a piecewise cubic Hermite interpolant to the data, that preserves monotonicity over ranges where the data points are monotonic. If the data points are only piecewise monotonic, the interpolant will have an extremum at each point where monotonicity switches direction. The estimates of the derivatives are computed by a formula due to Brodlie, which is described in Fritsch and Butland [1], with suitable changes at the boundary points.

The routine is derived from routine PCHIM in Fritsch [2].

Values of the computed interpolant, and of its first derivative and definite integral, can subsequently be computed by calling E01BFF, E01BGF and E01BHF, as described in Section 8.

4. References

5. Parameters

1: \(N\) -- INTEGER 
   Input
   On entry: \(n\), the number of data points. Constraint: \(N \geq 2\).

2: \(X(N)\) -- DOUBLE PRECISION array 
   Input
   On entry: \(X(r)\) must be set to \(x_r\), the \(r\)th value of the \(r\)
independent variable (abscissa), for \(r=1,2,\ldots,n\).
   Constraint: \(X(r) < X(r+1)\).

3: \(F(N)\) -- DOUBLE PRECISION array 
   Input
   On entry: \(F(r)\) must be set to \(f_r\), the \(r\)th value of the \(r\)
dependent variable (ordinate), for \( r=1,2,\ldots,n \).

4: \( D(N) \) -- DOUBLE PRECISION array Output
On exit: estimates of derivatives at the data points. \( D(r) \) contains the derivative at \( X(r) \).

5: \( IFAIL \) -- INTEGER Input/Output
On entry: \( IFAIL \) must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: \( IFAIL = 0 \) unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry \( IFAIL = 0 \) or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

\( IFAIL = 1 \)
On entry \( N < 2 \).

\( IFAIL = 2 \)
The values of \( X(r) \), for \( r=1,2,\ldots,N \), are not in strictly increasing order.

7. Accuracy

The computational errors in the array \( D \) should be negligible in most practical situations.

8. Further Comments

The time taken by the routine is approximately proportional to \( n \).

The values of the computed interpolant at the points \( PX(i) \), for \( i=1,2,\ldots,M \), may be obtained in the real array \( PF \), of length at least \( M \), by the call:

\[
\text{CALL E01BFF}(N,X,F,D,M,PX,PF,IFAIL)
\]

where \( N, X \) and \( F \) are the input parameters to E01BEF and \( D \) is the output parameter from E01BEF.

The values of the computed interpolant at the points \( PX(i) \), for \( i = 1,2,\ldots,M \), together with its first derivatives, may be obtained in the real arrays \( PF \) and \( PD \), both of length at least \( M \), by the
22.4. **NAGE.HT**

call:

\[
\text{CALL E01BGF(N,X,F,D,M,PX,PF,PD,IFAIL)}
\]

where \( N, X, F \) and \( D \) are as described above.

The value of the definite integral of the interpolant over the interval \( A \) to \( B \) can be obtained in the real variable \( \text{PINT} \) by the call:

\[
\text{CALL E01BHF(N,X,F,D,A,B,PINT,IFAIL)}
\]

where \( N, X, F \) and \( D \) are as described above.

9. Example

This example program reads in a set of data points, calls E01BEF to compute a piecewise monotonic interpolant, and then calls E01BFF to evaluate the interpolant at equally spaced points.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

CHAPTER 22. NAG LIBRARY ROUTINES

Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E01BFF evaluates a piecewise cubic Hermite interpolant at a set of points.

2. Specification

SUBROUTINE E01BFF (N, X, F, D, M, PX, PF, IFAIL)
INTEGER N, M, IFAIL
DOUBLE PRECISION X(N), F(N), D(N), PX(M), PF(M)

3. Description

This routine evaluates a piecewise cubic Hermite interpolant, as computed by E01BEF, at the points PX(i), for i=1,2,...,m. If any point lies outside the interval from X(1) to X(N), a value is extrapolated from the nearest extreme cubic, and a warning is returned.

The routine is derived from routine PCHFE in Fritsch [1].

4. References

5. Parameters

1: N -- INTEGER Input
2: X(N) -- DOUBLE PRECISION array Input
3: F(N) -- DOUBLE PRECISION array Input
4: D(N) -- DOUBLE PRECISION array Input
   On entry: N, X, F and D must be unchanged from the previous call of E01BEF.
5: M -- INTEGER Input
   On entry: m, the number of points at which the interpolant is to be evaluated. Constraint: M >= 1.
6: PX(M) -- DOUBLE PRECISION array Input
   On entry: the m values of x at which the interpolant is to be evaluated.
7: PF(M) -- DOUBLE PRECISION array
   Output
   On exit: PF(i) contains the value of the interpolant
   evaluated at the point PX(i), for i=1,2,...,M.

8: IFAIL -- INTEGER
   Input/Output
   On entry: IFAIL must be set to 0, -1 or 1. For users not
   familiar with this parameter (described in the Essential
   Introduction) the recommended value is 0.

   On exit: IFAIL = 0 unless the routine detects an error (see
   Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
   On entry N < 2.

IFAIL= 2
   The values of X(r), for r = 1,2,...,N, are not in strictly
   increasing order.

IFAIL= 3
   On entry M < 1.

IFAIL= 4
   At least one of the points PX(i), for i = 1,2,...,M, lies
   outside the interval [X(i),X(N)], and extrapolation was
   performed at all such points. Values computed at such points
   may be very unreliable.

7. Accuracy

The computational errors in the array PF should be negligible in
most practical situations.

8. Further Comments

The time taken by the routine is approximately proportional to
the number of evaluation points, m. The evaluation will be most
efficient if the elements of PX are in non-decreasing order (or,
more generally, if they are grouped in increasing order of the
intervals [X(r-1),X(r)]). A single call of E01BFF with m>1 is
more efficient than several calls with m=1.
9. Example

This example program reads in values of $N$, $X$, $F$ and $D$, and then calls E01BFF to evaluate the interpolant at equally spaced points.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

---

Piecewise cubic Hermite interpolant and 1st deriv

---

SUBROUTINE E01BGF (N, X, F, D, M, PX, PF, PD, IFAIL)
INTEGER N, M, IFAIL

1. Purpose

E01BGF evaluates a piecewise cubic Hermite interpolant and its first derivative at a set of points.

2. Specification

SUBROUTINE E01BGF (N, X, F, D, M, PX, PF, PD, IFAIL)
INTEGER N, M, IFAIL
3. Description

This routine evaluates a piecewise cubic Hermite interpolant, as computed by E01BEF, at the points PX(i), for i=1,2,...,m. The first derivatives at the points are also computed. If any point lies outside the interval from X(i) to X(N), values of the interpolant and its derivative are extrapolated from the nearest extreme cubic, and a warning is returned.

If values of the interpolant only, and not of its derivative, are required, E01BFF should be used.

The routine is derived from routine PCHFD in Fritsch [1].

4. References

5. Parameters

1: N -- INTEGER Input

2: X(N) -- DOUBLE PRECISION array Input

3: F(N) -- DOUBLE PRECISION array Input

4: D(N) -- DOUBLE PRECISION array Input
   On entry: N, X, F and D must be unchanged from the previous call of E01BEF.

5: M -- INTEGER Input
   On entry: m, the number of points at which the interpolant is to be evaluated. Constraint: M >= 1.

6: PX(M) -- DOUBLE PRECISION array Input
   On entry: the m values of x at which the interpolant is to be evaluated.

7: PF(M) -- DOUBLE PRECISION array Output
   On exit: PF(i) contains the value of the interpolant evaluated at the point PX(i), for i=1,2,...,m.

8: PD(M) -- DOUBLE PRECISION array Output
   On exit: PD(i) contains the first derivative of the interpolant evaluated at the point PX(i), for i=1,2,...,m.

9: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1
On entry N < 2.

IFAIL= 2
The values of X(r), for r = 1,2,...,N, are not in strictly increasing order.

IFAIL= 3
On entry M < 1.

IFAIL= 4
At least one of the points PX(i), for i = 1,2,...,M, lies outside the interval [X(1),X(N)], and extrapolation was performed at all such points. Values computed at these points may be very unreliable.

7. Accuracy

The computational errors in the arrays PF and PD should be negligible in most practical situations.

8. Further Comments

The time taken by the routine is approximately proportional to the number of evaluation points, m. The evaluation will be most efficient if the elements of PX are in non-decreasing order (or, more generally, if they are grouped in increasing order of the intervals [X(r-1),X(r)]). A single call of E01BGF with m>1 is more efficient than several calls with m=1.

9. Example

This example program reads in values of N, X, F and D, and calls E01BGF to compute the values of the interpolant and its derivative at equally spaced points.
The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

---

Definite integral of piecewise cubic Hermite interpolant

---

E01 -- Interpolation

E01BHF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E01BHF evaluates the definite integral of a piecewise cubic Hermite interpolant over the interval [a,b].

2. Specification

```
SUBROUTINE E01BHF (N, X, F, D, A, B, PINT, IFAIL)
INTEGER N, IFAIL
DOUBLE PRECISION X(N), F(N), D(N), A, B, PINT
```

3. Description

This routine evaluates the definite integral of a piecewise cubic Hermite interpolant, as computed by E01BEF, over the interval [a,b].
[a,b].

If either a or b lies outside the interval from X(1) to X(N) computation of the integral involves extrapolation and a warning is returned.

The routine is derived from routine PCHIA in Fritsch [1].

4. References

5. Parameters

1: N -- INTEGER Input
2: X(N) -- DOUBLE PRECISION array Input
3: F(N) -- DOUBLE PRECISION array Input
4: D(N) -- DOUBLE PRECISION array Input
   On entry: N, X, F and D must be unchanged from the previous call of E01BEF.
5: A -- DOUBLE PRECISION Input
6: B -- DOUBLE PRECISION Input
   On entry: the interval [a,b] over which integration is to be performed.
7: PINT -- DOUBLE PRECISION Output
   On exit: the value of the definite integral of the interpolant over the interval [a,b].
8: IFAIL -- INTEGER Input/Output
   On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
   On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).
IFAIL= 1
   On entry N < 2.

IFAIL= 2
   The values of X(r), for r = 1,2,...,N, are not in strictly increasing order.

IFAIL= 3
   On entry at least one of A or B lies outside the interval [X(1),X(N)], and extrapolation was performed to compute the integral. The value returned is therefore unreliable.

7. Accuracy

The computational error in the value returned for PINT should be negligible in most practical situations.

8. Further Comments

The time taken by the routine is approximately proportional to the number of data points included within the interval [a,b].

9. Example

This example program reads in values of N, X, F and D. It then reads in pairs of values for A and B, and evaluates the definite integral of the interpolant over the interval [A,B] until end-of-file is reached.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
1. Purpose

E01DAF computes a bicubic spline interpolating surface through a set of data values, given on a rectangular grid in the x-y plane.

2. Specification

```
SUBROUTINE E01DAF (MX, MY, X, Y, F, PX, PY, LAMDA, MU, C,
1         WRK, IFAIL)
INTEGER MX, MY, PX, PY, IFAIL
DOUBLE PRECISION X(MX), Y(MY), F(MX*MY), LAMDA(MX+4), MU(MX +4),
1         C(MX*MY), WRK((MX+6)*(MY+6))
```

3. Description

This routine determines a bicubic spline interpolant to the set of data points \((x_q, y_r, f_{q,r})\), for \(q=1,2,...,m\); \(r=1,2,...,m\). The spline is given in the B-spline representation

\[
s(x,y) = \sum_{i=1}^{m} \sum_{j=1}^{m} c_{ij} N_i(x) N_j(y),
\]

such that

\[
s(x_q, y_r) = f_{q,r},
\]

where \(N_i(x)\) and \(N_j(y)\) denote normalised cubic B-splines, the former defined on the knots \((\lambda_i)\) to \((\lambda_{i+4})\) and the

latter on the knots (mu) to (mu) , and the c are the spline
j j+4 ij
coefficients. These knots, as well as the coefficients, are
determined by the routine, which is derived from the routine
B2IRE in Anthony et al[1]. The method used is described in
Section 8.2.

For further information on splines, see Hayes and Halliday [4]

Values of the computed spline can subsequently be obtained by
calling E02DEF or E02DFF as described in Section 8.3.

4. References

    Approximation Subroutine Library. National Physical
    Laboratory.

    Theory. 6 50--62.

    Appl. 14 89--103.

5. Parameters

1: MX -- INTEGER      Input

2: MY -- INTEGER      Input
    On entry: MX and MY must specify m and m respectively,
    x y
    the number of points along the x and y axis that define the

3: X(MX) -- DOUBLE PRECISION array      Input

4: Y(MY) -- DOUBLE PRECISION array      Input
    On entry: X(q) and Y(r) must contain x , for q=1,2,...,m ,
    q x
    and y , for r=1,2,...,m , respectively. Constraints:
    r y
    X(q) < X(q+1), for q=1,2,...,m -1,
    x
    Y(r) < Y(r+1), for r=1,2,...,m -1.
5: F(MX*MY) -- DOUBLE PRECISION array Input
On entry: F(m *(q-1)+r) must contain f , for q=1,2,...,m ;
y q,r x
r=1,2,...,m.

6: PX -- INTEGER Output
7: PY -- INTEGER Output
On exit: PX and PY contain m +4 and m +4, the total number
of knots of the computed spline with respect to the x and y
variables, respectively.

8: LAMDA(MX+4) -- DOUBLE PRECISION array Output
On exit: LAMDA contains the complete set of knots (lambda)
i associated with the x variable, i.e., the interior knots
LAMDA(5), LAMDA(6), ..., LAMDA(PX-4), as well as the
additional knots LAMDA(1) = LAMDA(2) = LAMDA(3) = LAMDA(4) =
X(1) and LAMDA(PX-3) = LAMDA(PX-2) = LAMDA(PX-1) = LAMDA(PX) =
X(MX) needed for the B-spline representation. MU contains
the corresponding complete set of knots (mu) associated
i
with the y variable.

9: MU(MY+4) -- DOUBLE PRECISION array Output
On exit: MU contains the complete set of knots (mu)
i associated
with the y variable.

10: C(MX*MY) -- DOUBLE PRECISION array Output
On exit: the coefficients of the spline interpolant. C(y
m *(i-1)+j) contains the coefficient c described in
y ij
Section 3.

11: WRK((MX+6)*(MY+6)) -- DOUBLE PRECISION array Workspace

12: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not
familiar with this parameter (described in the Essential
Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see
Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:
If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1
On entry MX < 4,

or  MY < 4.

IFAIL= 2
On entry either the values in the X array or the values in the Y array are not in increasing order.

IFAIL= 3
A system of linear equations defining the B-spline coefficients was singular; the problem is too ill-conditioned to permit solution.

7. Accuracy
The main sources of rounding errors are in steps (2), (3), (6) and (7) of the algorithm described in Section 8.2. It can be shown (Cox [2]) that the matrix $A$ formed in step (2) has $x$ elements differing relatively from their true values by at most a small multiple of $3(\epsilon)$, where $\epsilon$ is the machine precision. $A$ is 'totally positive', and a linear system with $x$ such a coefficient matrix can be solved quite safely by elimination without pivoting. Similar comments apply to steps (6) and (7). Thus the complete process is numerically stable.

8. Further Comments

8.1. Timing
The time taken by this routine is approximately proportional to $m^m$. $x$ $y$

8.2. Outline of method used
The process of computing the spline consists of the following steps:

(1) choice of the interior x-knots (lambda)$_5$, (lambda)$_6$, ..., (lambda)$_{m-2}$, for $i=5,6,\ldots,m$, (lambda)$_m$ = x, (lambda)$_m$ = x
(2) formation of the system
\[ A \cdot E = F, \]
where \( A \) is a band matrix of order \( m \) and bandwidth 4, containing in its \( q \)th row the values at \( x \) of the B-splines \( q \) in \( x \), \( F \) is the \( m \) by \( m \) rectangular matrix of values \( f_{q,r} \), and \( E \) denotes an \( m \) by \( m \) rectangular matrix of intermediate coefficients,

(3) use of Gaussian elimination to reduce this system to band triangular form,

(4) solution of this triangular system for \( E \),

(5) choice of the interior \( y \) knots \( (\mu_5), (\mu_6), \ldots, (\mu_m) \) as \( y \)
\[ \mu_i = y_i \text{ for } i=5,6,\ldots,m, \]
\( y \)

(6) formation of the system
\[ A \cdot C = E, \]
where \( A \) is the counterpart of \( A \) for the \( y \) variable, and \( C \) denotes the \( m \) by \( m \) rectangular matrix of values of \( c_{ij} \),

(7) use of Gaussian elimination to reduce this system to band triangular form,

(8) solution of this triangular system for \( C \) and hence \( C \).

For computational convenience, steps (2) and (3), and likewise steps (6) and (7), are combined so that the formation of \( A \) and \( A \) and the reductions to triangular form are carried out one row at a time.

8.3. Evaluation of Computed Spline

The values of the computed spline at the points \((TX(r),TY(r))\), for \( r = 1,2,\ldots,N \), may be obtained in the double precision array
FF, of length at least N, by the following call:

IFAIL = 0  
call E02DEF(N,PX,PY,TX,TY,LAMDA,MU,C,FF,WRK,IWRK,IFAIL)

where PX, PY, LAMDA, MU and C are the output parameters of E01DAF,
WRK is a double precision workspace array of length at least
PY-4, and IWRK is an integer workspace array of length at least
PY-4.

To evaluate the computed spline on an NX by NY rectangular grid
of points in the x-y plane, which is defined by the x co-
ordinates stored in TX(q), for q = 1,2,...,NX, and the y co-
ordinates stored in TY(r), for r = 1,2,...,NY, returning the
results in the double precision array FG which is of length at
least NX*NY, the following call may be used:

IFAIL = 0  
call E02DFF(NX,NY,PX,PY,TX,TY,LAMDA,MU,C,FG,WRK,LWRK,
   *       IWRK,LIWRK,IFAIL)

where PX, PY, LAMDA, MU and C are the output parameters of E01DAF,
WRK is a double precision workspace array of length at least
LWRK = min(NWRK1,NWRK2), NWRK1 = NX*4+PX, NWRK2 = NY*4+PY, and
IWRK is an integer workspace array of length at least LIWRK = NY + PY - 4 if NWRK1 > NWRK2, or NX + PX - 4 otherwise. The result
of the spline evaluated at grid point (q,r) is returned in
element (NY*(q-1)+r) of the array FG.

9. Example

This program reads in values of m, x for q=1,2,...,m, m and
x   y for r=1,2,...,m, followed by values of the ordinates f
r   y defined at the grid points (x,y). It then calls E01DAF to
q   r compute a bicubic spline interpolant of the data values, and
prints the values of the knots and B-spline coefficients. Finally
it evaluates the spline at a small sample of points on a
rectangular grid.

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.
Two-D surface interpolating a set of scattered data points

--- nage.ht ---

--- manpageXXe01saf ---

E01SAF generates a two-dimensional surface interpolating a set of scattered data points, using the method of Renka and Cline.

2. Specification

SUBROUTINE E01SAF (M, X, Y, F, TRIANG, GRADS, IFAIL)
INTEGER M, TRIANG(7*M), IFAIL
DOUBLE PRECISION X(M), Y(M), F(M), GRADS(2,M)

3. Description

This routine constructs an interpolating surface F(x,y) through a set of m scattered data points (x_r, y_r, f_r), for r=1,2,...,m, using a method due to Renka and Cline. In the (x,y) plane, the data points must be distinct. The constructed surface is continuous and has continuous first derivatives.

The method involves firstly creating a triangulation with all the
22.4. NAGE.HT

(x,y) data points as nodes, the triangulation being as nearly equiangular as possible (see Cline and Renka [1]). Then gradients in the x- and y-directions are estimated at node r, for r=1,2,...,m, as the partial derivatives of a quadratic function of x and y which interpolates the data value f, and which fits the data values at nearby nodes (those within a certain distance chosen by the algorithm) in a weighted least-squares sense. The weights are chosen such that closer nodes have more influence than more distant nodes on derivative estimates at node r. The computed partial derivatives, with the f values, at the three nodes of each triangle define a piecewise polynomial surface of a certain form which is the interpolant on that triangle. See Renka and Cline [4] for more detailed information on the algorithm, a development of that by Lawson [2]. The code is derived from Renka [3].

The interpolant F(x,y) can subsequently be evaluated at any point (x,y) inside or outside the domain of the data by a call to E01SBF. Points outside the domain are evaluated by extrapolation.

4. References

5. Parameters

1: M -- INTEGER Input
   On entry: m, the number of data points. Constraint: M >= 3.

2: X(M) -- DOUBLE PRECISION array Input

3: Y(M) -- DOUBLE PRECISION array Input
4: F(M) -- DOUBLE PRECISION array Input
   On entry: the co-ordinates of the rth data point, for
   r=1,2,...,m. The data points are accepted in any order, but
   see Section 8. Constraint: The (x,y) nodes must not all be
   collinear, and each node must be unique.

5: TRIANG(7*M) -- INTEGER array Output
   On exit: a data structure defining the computed
   triangulation, in a form suitable for passing to E01SBF.

6: GRADS(2,M) -- DOUBLE PRECISION array Output
   On exit: the estimated partial derivatives at the nodes, in
   a form suitable for passing to E01SBF. The derivatives at
   node r with respect to x and y are contained in GRADS(1,r)
   and GRADS(2,r) respectively, for r=1,2,...,m.

7: IFAIL -- INTEGER Input/Output
   On entry: IFAIL must be set to 0, -1 or 1. For users not
   familiar with this parameter (described in the Essential
   Introduction) the recommended value is 0.
   On exit: IFAIL = 0 unless the routine detects an error (see
   Section 6).

6. Error Indicators and Warnings
   Errors detected by the routine:
   If on entry IFAIL = 0 or -1, explanatory error messages are
   output on the current error message unit (as defined by X04AAF).

   IFAIL= 1
   On entry M < 3.

   IFAIL= 2
   On entry all the (X,Y) pairs are collinear.

   IFAIL= 3
   On entry (X(i),Y(i)) = (X(j),Y(j)) for some i/=j.

7. Accuracy
   On successful exit, the computational errors should be negligible
   in most situations but the user should always check the computed
   surface for acceptability, by drawing contours for instance. The
   surface always interpolates the input data exactly.

8. Further Comments
   The time taken for a call of E01SAF is approximately proportional
to the number of data points, \( m \). The routine is more efficient if, before entry, the values in \( X, Y, F \) are arranged so that the \( X \) array is in ascending order.

9. Example

This program reads in a set of 30 data points and calls E01SAF to construct an interpolating surface. It then calls E01SBF to evaluate the interpolant at a sample of points on a rectangular grid.

Note that this example is not typical of a realistic problem: the number of data points would normally be larger, and the interpolant would need to be evaluated on a finer grid to obtain an accurate plot, say.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

---

Evaluate 2D interpolant function from E01SAF

--- nage.ht ---
1. Purpose

E01SBF evaluates at a given point the two-dimensional interpolant function computed by E01SAF.

2. Specification

```subroutine e01sbf (m, x, y, f, triang, grads, px, py, pf, 1
    integer m, triang(7*m), ifail
    double precision x(m), y(m), f(m), grads(2,m), px, py, pf```

3. Description

This routine takes as input the parameters defining the interpolant \( F(x,y) \) of a set of scattered data points \( (x_r, y_r, f_r) \), for \( r = 1, 2, \ldots, m \), as computed by E01SAF, and evaluates the interpolant at the point \( (px, py) \).

If \( (px, py) \) is equal to \( (x_r, y_r) \) for some value of \( r \), the returned value will be equal to \( f_r \).

If \( (px, py) \) is not equal to \( (x_r, y_r) \) for any \( r \), the derivatives in \( \text{GRADS} \) will be used to compute the interpolant. A triangle is sought which contains the point \( (px, py) \), and the vertices of the triangle along with the partial derivatives and \( f \) values at the vertices are used to compute the value \( F(px, py) \). If the point \( (px, py) \) lies outside the triangulation defined by the input parameters, the returned value is obtained by extrapolation. In this case, the interpolating function \( F \) is extended linearly beyond the triangulation boundary. The method is described in more detail in Renka and Cline [2] and the code is derived from Renka [1].

E01SBF must only be called after a call to E01SAF.

4. References

5. Parameters

1:  M -- INTEGER  \hspace{1cm} \text{Input}

2:  X(M) -- DOUBLE PRECISION array \hspace{1cm} \text{Input}

3:  Y(M) -- DOUBLE PRECISION array \hspace{1cm} \text{Input}

4:  F(M) -- DOUBLE PRECISION array \hspace{1cm} \text{Input}

5:  TRIANG(7*M) -- INTEGER array \hspace{1cm} \text{Input}

6:  GRADS(2,M) -- DOUBLE PRECISION array \hspace{1cm} \text{Input}
   
   On entry: M, X, Y, F, TRIANG and GRADS must be unchanged
   from the previous call of E01SAF.

7:  PX -- DOUBLE PRECISION \hspace{1cm} \text{Input}

8:  PY -- DOUBLE PRECISION \hspace{1cm} \text{Input}
   
   On entry: the point (px,py) at which the interpolant is to
   be evaluated.

9:  PF -- DOUBLE PRECISION \hspace{1cm} \text{Output}
   
   On exit: the value of the interpolant evaluated at the
   point (px,py).

10: IFAIL -- INTEGER \hspace{1cm} \text{Input/Output}
     
     On entry: IFAIL must be set to 0, -1 or 1. For users not
     familiar with this parameter (described in the Essential
     Introduction) the recommended value is 0.

     On exit: IFAIL = 0 unless the routine detects an error (see
     Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
   On entry M < 3.

IFAIL= 2
   On entry the triangulation information held in the array
   TRIANG does not specify a valid triangulation of the data
   points. TRIANG may have been corrupted since the call to
E01SAF.

IFAIL = 3
The evaluation point (PX, PY) lies outside the nodal triangulation, and the value returned in PF is computed by extrapolation.

7. Accuracy
Computational errors should be negligible in most practical situations.

8. Further Comments
The time taken for a call of E01SBF is approximately proportional to the number of data points, m.

The results returned by this routine are particularly suitable for applications such as graph plotting, producing a smooth surface from a number of scattered points.

9. Example
See the example for E01SAF.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

Generate 2D surface interpolating a scattered data points

---

\end{verbatim}
\endscroll
\end{page}
1. Purpose

E01SEF generates a two-dimensional surface interpolating a set of scattered data points, using a modified Shepard method.

2. Specification

```fortran
SUBROUTINE E01SEF (M, X, Y, F, RNW, RNQ, NW, NQ, FNODES, 1 MINNQ, WRK, IFAIL)
INTEGER M, NW, NQ, MINNQ, IFAIL
DOUBLE PRECISION X(M), Y(M), F(M), RNW, RNQ, FNODES(5*M), 1 WRK(6*M)
```

3. Description

This routine constructs an interpolating surface \( F(x,y) \) through a set of \( m \) scattered data points \( (x_r,y_r,f_r) \), for \( r=1,2,...,m \), using a modification of Shepard's method. The surface is continuous and has continuous first derivatives.

The basic Shepard method, described in [2], interpolates the input data with the weighted mean

\[
F(x,y) = \frac{\sum_{r=1}^{m} w(x,y) f_r}{\sum_{r=1}^{m} w(x,y)},
\]

where \( w(x,y) = \frac{1}{d} \) and \( d = (x-x_r)^2 + (y-y_r)^2 \).
The basic method is global in that the interpolated value at any point depends on all the data, but this routine uses a modification due to Franke and Nielson described in [1], whereby the method becomes local by adjusting each \( w(x,y) \) to be zero outside a circle with centre \((x_r, y_r)\) and some radius \(R_r\). Also, to improve the performance of the basic method, each \( f \) above is replaced by a function \( f(x,y) \), which is a quadratic fitted by weighted least-squares to data local to \((x_r, y_r)\) and forced to interpolate \((x_r, y_r, f)\). In this context, a point \((x_r, y_r)\) is defined to be local to another point if it lies within some distance \(R_q\) of it. Computation of these quadratics constitutes the main work done by this routine. If there are less than 5 other points within distance \(R_q\) from \((x_r, y_r)\), the quadratic is replaced by a linear function. In cases of rank-deficiency, the minimum norm solution is computed.

The user may specify values for \(R_r\) and \(R_q\), but it is usually easier to choose instead two integers \(N_w\) and \(N_q\), from which the routine will compute \(R_r\) and \(R_q\). These integers can be thought of as the average numbers of data points lying within distances \(R_w\) and \(R_q\) respectively from each node. Default values are provided, and advice on alternatives is given in Section 8.2.

The interpolant \(F(x,y)\) generated by this routine can subsequently be evaluated for any point \((x,y)\) in the domain of the data by a call to E01SFF.

4. References

5. Parameters

1: M -- INTEGER Input
   On entry: m, the number of data points. Constraint: M >= 3.

2: X(M) -- DOUBLE PRECISION array Input
3: Y(M) -- DOUBLE PRECISION array Input
4: F(M) -- DOUBLE PRECISION array Input
   On entry: the co-ordinates of the rth data point, for
   r=1,2,...,m. The order of the data points is immaterial.
   Constraint: each of the (X(r),Y(r)) pairs must be unique.

5: RNW -- DOUBLE PRECISION Input/Output
6: RNQ -- DOUBLE PRECISION Input/Output
   On entry: suitable values for the radii R and R_w, w_q
   described in Section 3. Constraint: RNQ <= 0 or 0 < RNW <= RNQ. On exit: if RNQ is set less than or equal to zero on
   entry, then default values for both of them will be computed
   from the parameters NW and NQ, and RNW and RNQ will contain
   these values on exit.

7: NW -- INTEGER Input
8: NQ -- INTEGER Input
   On entry: if RNQ > 0.0 and RNW > 0.0 then NW and NQ are not
   referenced by the routine. Otherwise, NW and NQ must specify
   suitable values for the integers N_w and N_q described in
   Section 3.

   If NQ is less than or equal to zero on entry, then default
   values for both of them, namely NW = 9 and NQ = 18, will be
   used. Constraint: NQ <= 0 or 0 < NW <= NQ.

9: FNODES(5*M) -- DOUBLE PRECISION array Output
   On exit: the coefficients of the constructed quadratic
   nodal functions. These are in a form suitable for passing to
   E01SFF.

10: MINNQ -- INTEGER Output
    On exit: the minimum number of data points that lie within
    radius RNQ of any node, and thus define a nodal function. If
    MINNQ is very small (say, less than 5), then the interpolant
    may be unsatisfactory in regions where the data points are
sparse.

11: WRK(6*M) -- DOUBLE PRECISION array Workspace

12: IFAIL -- INTEGER Input/Output
   On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
   On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1
   On entry M < 3.

IFAIL= 2
   On entry RNQ > 0 and either RNW > RNQ or RNW <= 0.

IFAIL= 3
   On entry NQ > 0 and either NW > NQ or NW <= 0.

IFAIL= 4
   On entry (X(i),Y(i)) is equal to (X(j),Y(j)) for some i/=j.

7. Accuracy

On successful exit, the computational errors should be negligible in most situations but the user should always check the computed surface for acceptability, by drawing contours for instance. The surface always interpolates the input data exactly.

8. Further Comments

8.1. Timing

The time taken for a call of E01SEF is approximately proportional to the number of data points, m, provided that N is of the same order as its default value (18). However if N is increased so that the method becomes more global, the time taken becomes approximately proportional to m .
8.2. Choice of $N_w$ and $N_q$

Note first that the radii $R_w$ and $R_q$, described in Section 3, are
computed as $D/w$ and $D/q$ respectively, where $D$ is the maximum distance between any pair of data points. Default values $N_w=9$ and $N_q=18$ work quite well when the data points are fairly uniformly distributed. However, for data having some regions with relatively few points or for small data sets ($m<25$), a larger value of $N$ may be needed. This is to ensure a reasonable number of data points within a distance $R$ of each node, and to avoid some regions in the data area being left outside all the discs of radius $R$ on which the weights $w(x,y)$ are non-zero. Maintaining $N$ approximately equal to $2N_q$ is usually an advantage.

Note however that increasing $N_w$ and $N_q$ does not improve the quality of the interpolant in all cases. It does increase the computational cost and makes the method less local.

9. Example

This program reads in a set of 30 data points and calls E01SEF to construct an interpolating surface. It then calls E01SFF to evaluate the interpolant at a sample of points on a rectangular grid.

Note that this example is not typical of a realistic problem: the number of data points would normally be larger, and the interpolant would need to be evaluated on a finer grid to obtain an accurate plot, say.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
Evaluate 2D interpolating function from E01SEF

\begin{verbatim}
E01SFF(3NAG) Foundation Library (12/10/92) E01SFF(3NAG)

E01 -- Interpolation E01SFF
E01SFF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E01SFF evaluates at a given point the two-dimensional interpolating function computed by E01SEF.

2. Specification

\begin{verbatim}
SUBROUTINE E01SFF (M, X, Y, F, RNW, FNODES, PX, PY, PF, 1
           INTEGER M, IFAIL)
    INTEGER M, IFAIL
    DOUBLE PRECISION X(M), Y(M), F(M), RNW, FNODES(5*M), PX, 1
          PY, PF
\end{verbatim}

3. Description

This routine takes as input the interpolant F(x,y) of a set of scattered data points \((x_{r}, y_{r}, f_{r})\), for \(r=1,2,\ldots,m\), as computed by E01SEF, and evaluates the interpolant at the point \((px,py)\).

If \((px,py)\) is equal to \((x_{r}, y_{r})\) for some value of \(r\), the returned value is \(f_{r}\). Otherwise, it returns the value of the interpolant at \((px,py)\).
value will be equal to \( f \).

If \((px,py)\) is not equal to \((x,y)\) for any \(r\), all points that are within distance \(RNW\) of \((px,py)\), along with the corresponding nodal functions given by \(FNODES\), will be used to compute a value of the interpolant.

\text{E01SFF\ must\ only\ be\ called\ after\ a\ call\ to\ E01SEF.}

4. References

5. Parameters

1: \(M\) -- INTEGER Input
2: \(X(M)\) -- DOUBLE PRECISION array Input
3: \(Y(M)\) -- DOUBLE PRECISION array Input
4: \(F(M)\) -- DOUBLE PRECISION array Input
5: \(RNW\) -- DOUBLE PRECISION Input
6: \(FNODES(5*M)\) -- DOUBLE PRECISION array Input
On entry: \(M, X, Y, F, RNW\) and \(FNODES\) must be unchanged from the previous call of \text{E01SEF}.
7: \(PX\) -- DOUBLE PRECISION Input
8: \(PY\) -- DOUBLE PRECISION Input
On entry: the point \((px,py)\) at which the interpolant is to be evaluated.
9: \(PF\) -- DOUBLE PRECISION Output
On exit: the value of the interpolant evaluated at the point \((px,py)\).
10: \(IFAIL\) -- INTEGER Input/Output
On entry: \(IFAIL\) must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential
CHAPTER 22. NAG LIBRARY ROUTINES

Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1
On entry M < 3.

IFAIL= 2
The interpolant cannot be evaluated because the evaluation point (PX,PY) lies outside the support region of the data supplied in X, Y and F. This error exit will occur if (PX,PY) lies at a distance greater than or equal to RNW from every point given by arrays X and Y.

The value 0.0 is returned in PF. This value will not provide continuity with values obtained at other points (PX,PY), i.e., values obtained when IFAIL = 0 on exit.

7. Accuracy

Computational errors should be negligible in most practical situations.

8. Further Comments

The time taken for a call of E01SFF is approximately proportional to the number of data points, m.

The results returned by this routine are particularly suitable for applications such as graph plotting, producing a smooth surface from a number of scattered points.

9. Example

See the example for E01SEF.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
Curve and Surface Fitting

      2.2.1. Representation of polynomials
      2.2.2. Representation of cubic splines
   2.3. Surface Fitting
      2.3.1. Bicubic splines: definition and representation
   2.4. General Linear and Nonlinear Fitting Functions
   2.5. Constrained Problems
1. Scope of the Chapter

The main aim of this chapter is to assist the user in finding a function which approximates a set of data points. Typically the data contain random errors, as of experimental measurement, which need to be smoothed out. To seek an approximation to the data, it is first necessary to specify for the approximating function a
mathematical form (a polynomial, for example) which contains a number of unspecified coefficients: the appropriate fitting routine then derives for the coefficients the values which provide the best fit of that particular form. The chapter deals mainly with curve and surface fitting (i.e., fitting with functions of one and of two variables) when a polynomial or a cubic spline is used as the fitting function, since these cover the most common needs. However, fitting with other functions and/or more variables can be undertaken by means of general linear or nonlinear routines (some of which are contained in other chapters) depending on whether the coefficients in the function occur linearly or nonlinearly. Cases where a graph rather than a set of data points is given can be treated simply by first reading a suitable set of points from the graph.

The chapter also contains routines for evaluating, differentiating and integrating polynomial and spline curves and surfaces, once the numerical values of their coefficients have been determined.

2. Background to the Problems

2.1. Preliminary Considerations

In the curve-fitting problems considered in this chapter, we have a dependent variable $y$ and an independent variable $x$, and we are given a set of data points $(x^r, y^r)$, for $r=1,2,...,m$. The preliminary matters to be considered in this section will, for simplicity, be discussed in this context of curve-fitting problems. In fact, however, these considerations apply equally well to surface and higher-dimensional problems. Indeed, the discussion presented carries over essentially as it stands if, for these cases, we interpret $x$ as a vector of several independent variables and correspondingly each $x^r$ as a vector containing the $r$th data value of each independent variable.

We wish, then, to approximate the set of data points as closely as possible with a specified function, $f(x)$ say, which is as smooth as possible -- $f(x)$ may, for example, be a polynomial. The requirements of smoothness and closeness conflict, however, and a balance has to be struck between them. Most often, the smoothness requirement is met simply by limiting the number of coefficients allowed in the fitting function -- for example, by restricting the degree in the case of a polynomial. Given a particular number of coefficients in the function in question, the fitting routines of this chapter determine the values of the coefficients such that the 'distance' of the function from the data points is as small as possible. The necessary balance is struck by the user.
comparing a selection of such fits having different numbers of coefficients. If the number of coefficients is too low, the approximation to the data will be poor. If the number is too high, the fit will be too close to the data, essentially following the random errors and tending to have unwanted fluctuations between the data points. Between these extremes, there is often a group of fits all similarly close to the data points and then, particularly when least-squares polynomials are used, the choice is clear: it is the fit from this group having the smallest number of coefficients.

The above process can be seen as the user minimizing the smoothness measure (i.e., the number of coefficients) subject to the distance from the data points being acceptably small. Some of the routines, however, do this task themselves. They use a different measure of smoothness (in each case one that is continuous) and minimize it subject to the distance being less than a threshold specified by the user. This is a much more automatic process, requiring only some experimentation with the threshold.

2.1.1. Fitting criteria: norms

A measure of the above 'distance' between the set of data points and the function \( f(x) \) is needed. The distance from a single data point \((x_r, y_r)\) to the function can simply be taken as

\[
(\epsilon)_r = y_r - f(x_r), \quad (1)
\]

and is called the residual of the point. (With this definition, the residual is regarded as a function of the coefficients contained in \( f(x) \); however, the term is also used to mean the particular value of \( (\epsilon)_r \) which corresponds to the fitted values of the coefficients.) However, we need a measure of distance for the set of data points as a whole. Three different measures are used in the different routines (which measure to select, according to circumstances, is discussed later in this sub-section). With \( (\epsilon)_r \) defined in (1), these measures, or norms, are

\[
m \sum_{r=1}^{m} |(\epsilon)_r|, \quad (2)
\]
respectively the $l_1$ norm, the $l_2$ norm and the $l_{\infty}$ norm.

Minimization of one or other of these norms usually provides the fitting criterion, the minimization being carried out with respect to the coefficients in the mathematical form used for $f(x)$: with respect to the $b$ for example if the mathematical form is the power series in (8) below. The fit which results from minimizing (2) is known as the $l_1$ fit, or the fit in the $l_1$ norm: that which results from minimizing (3) is the $l_2$ fit, the well-known least-squares fit (minimizing (3) is equivalent to minimizing the square of (3), i.e., the sum of squares of residuals, and it is the latter which is used in practice), and that from minimizing (4) is the $l_{\infty}$, or minimax, fit.

Strictly speaking, implicit in the use of the above norms are the statistical assumptions that the random errors in the $y$ are independent of one another and that any errors in the $x$ are negligible by comparison. From this point of view, the use of the $l_1$ norm is appropriate when the random errors in the $y$ have a normal distribution, and the $l_2$ norm is appropriate when they have a rectangular distribution, as when fitting a table of values rounded to a fixed number of decimal places. The $l_1$ norm is appropriate when the error distribution has its frequency function proportional to the negative exponential of the modulus of the normalised error -- not a common situation.

However, the user is often indifferent to these statistical considerations, and simply seeks a fit which he can assess by inspection, perhaps visually from a graph of the results. In this
event, the $l_1$ norm is particularly appropriate when the data are thought to contain some 'wild' points (since fitting in this norm tends to be unaffected by the presence of a small number of such points), though of course in simple situations the user may prefer to identify and reject these points. The $l_\infty$ norm should be used only when the maximum residual is of particular concern, as may be the case for example when the data values have been obtained by accurate computation, as of a mathematical function. Generally, however, a routine based on least-squares should be preferred, as being computationally faster and usually providing more information on which to assess the results. In many problems the three fits will not differ significantly for practical purposes.

Some of the routines based on the $l_1$ norm do not minimize the $l_2$ norm itself but instead minimize some (intuitively acceptable) measure of smoothness subject to the norm being less than a user-specified threshold. These routines fit with cubic or bicubic splines (see (10) and (14) below) and the smoothing measures relate to the size of the discontinuities in their third derivatives. A much more automatic fitting procedure follows from this approach.

2.1.2. Weighting of data points

The use of the above norms also assumes that the data values $y_r$ are of equal (absolute) accuracy. Some of the routines enable an allowance to be made to take account of differing accuracies. The allowance takes the form of 'weights' applied to the $y$-values so that those values known to be more accurate have a greater influence on the fit than others. These weights, to be supplied by the user, should be calculated from estimates of the absolute accuracies of the $y$-values, these estimates being expressed as standard deviations, probable errors or some other measure which has the same dimensions as $y$. Specifically, for each $y$ the corresponding weight $w_r$ should be inversely proportional to the accuracy estimate of $y_r$. For example, if the percentage accuracy is the same for all $y$, then the absolute accuracy of $y$ is proportional to $y$ (assuming $y$ to be positive, as it usually is in such cases) and so $w_r = K/y$, for $r=1,2,...,m$, for an arbitrary

$r$
positive constant $K$. (This definition of weight is stressed
because often weight is defined as the square of that used here.)
The norms (2), (3) and (4) above are then replaced respectively
by

\[
m \quad -- \quad |w(\epsilon)|, \quad \text{for} \quad r = 1, 2, \ldots, m \quad \text{(5)}
\]

\[
\max |w(\epsilon)|. \quad \text{for} \quad r = 1, 2, \ldots, m \quad \text{(7)}
\]

Again it is the square of (6) which is used in practice rather
than (6) itself.

2.2. Curve Fitting

When, as is commonly the case, the mathematical form of the
fitting function is immaterial to the problem, polynomials and
cubic splines are to be preferred because their simplicity and
ease of handling confer substantial benefits. The cubic spline is
the more versatile of the two. It consists of a number of cubic
polynomial segments joined end to end with continuity in first
and second derivatives at the joins. The third derivative at the
joins is in general discontinuous. The $x$-values of the joins are
called knots, or, more precisely, interior knots. Their number
determines the number of coefficients in the spline, just as the
degree determines the number of coefficients in a polynomial.

2.2.1. Representation of polynomials

Rather than using the power-series form

\[
f(x) = b_0 + b_1 x + b_2 x^2 + \cdots + b_k x^k \quad \text{(8)}
\]

to represent a polynomial, the routines in this chapter use the
Chebyshev series form
1 \texttt{f(x)== -a T_0(x)+a T_1(x)+a T_2(x)+...+a T_k(x),} \tag{9} \\
2 \texttt{0 0 1 1 2 2 k k}

where $T_i(x)$ is the Chebyshev polynomial of the first kind of degree $i$ (see Cox and Hayes [1], page 9), and where the range of $x$ has been normalised to run from -1 to +1. The use of either form leads theoretically to the same fitted polynomial, but in practice results may differ substantially because of the effects of rounding error. The Chebyshev form is to be preferred, since it leads to much better accuracy in general, both in the computation of the coefficients and in the subsequent evaluation of the fitted polynomial at specified points. This form also has other advantages: for example, since the later terms in (9) generally decrease much more rapidly from left to right than do those in (8), the situation is more often encountered where the last terms are negligible and it is obvious that the degree of the polynomial can be reduced (note that on the interval $-1 \leq x \leq 1$ for all $i$, $T_i(x)$ attains the value unity but never exceeds it, so that the coefficient $a_i$ gives directly the maximum value of the $i$ term containing it).

2.2.2. Representation of cubic splines

A cubic spline is represented in the form

\[ f(x) = c N_1(x) + c N_2(x) + ... + c N_p(x), \tag{10} \]

where $N_i(x)$, for $i=1,2,...,p$, is a normalised cubic B-spline (see Hayes [2]). This form, also, has advantages of computational speed and accuracy over alternative representations.

2.3. Surface Fitting

There are now two independent variables, and we shall denote these by $x$ and $y$. The dependent variable, which was denoted by $y$ in the curve-fitting case, will now be denoted by $f$. (This is a rather different notation from that indicated for the general-dimensional problem in the first paragraph of Section 2.1, but it has some advantages in presentation.)

Again, in the absence of contrary indications in the particular application being considered, polynomials and splines are the approximating functions most commonly used. Only splines are used by the surface-fitting routines in this chapter.
2.3.1. Bicubic splines: definition and representation

The bicubic spline is defined over a rectangle $R$ in the $(x,y)$ plane, the sides of $R$ being parallel to the $x$- and $y$-axes. $R$ is divided into rectangular panels, again by lines parallel to the axes. Over each panel the bicubic spline is a bicubic polynomial, that is it takes the form

$$
\sum_{i=0}^{3} \sum_{j=0}^{3} a_{ij} x^i y^j.
$$

Each of these polynomials joins the polynomials in adjacent panels with continuity up to the second derivative. The constant $x$-values of the dividing lines parallel to the $y$-axis form the set of interior knots for the variable $x$, corresponding precisely to the set of interior knots of a cubic spline. Similarly, the constant $y$-values of dividing lines parallel to the $x$-axis form the set of interior knots for the variable $y$. Instead of representing the bicubic spline in terms of the above set of bicubic polynomials, however, it is represented, for the sake of computational speed and accuracy, in the form

$$
\sum_{i=1}^{p} \sum_{j=1}^{q} c_{ij} M_i(x) N_j(y),
$$

where $M_i(x)$, for $i=1,2,\ldots,p$, and $N_j(y)$, for $j=1,2,\ldots,q$, are normalised B-splines (see Hayes and Halliday [4] for further details of bicubic splines and Hayes [2] for normalised B-splines).

2.4. General Linear and Nonlinear Fitting Functions

We have indicated earlier that, unless the data-fitting application under consideration specifically requires some other type of fitting function, a polynomial or a spline is usually to be preferred. Special routines for these functions, in one and in two variables, are provided in this chapter. When the application does specify some other fitting function, however, it may be treated by a routine which deals with a general linear function, or by one for a general nonlinear function, depending on whether the coefficients in the given function occur linearly or nonlinearly.
The general linear fitting function can be written in the form

\[ f(x) = c_1 (\phi_1(x)) + c_2 (\phi_2(x)) + \ldots + c_p (\phi_p(x)), \quad (15) \]

where \( x \) is a vector of one or more independent variables, and the \( \phi_i \) are any given functions of these variables (though they must be linearly independent of one another if there is to be the possibility of a unique solution to the fitting problem). This is not intended to imply that each \( \phi_i \) is necessarily a function of all the variables; we may have, for example, that each \( \phi_i \) is a function of a different single variable, and even that one of the \( \phi_i \) is a constant. All that is required is that a value of each \( \phi_i(x) \) can be computed when a value of each independent variable is given.

When the fitting function \( f(x) \) is not linear in its coefficients, no more specific representation is available in general than \( f(x) \) itself. However, we shall find it helpful later on to indicate the fact that \( f(x) \) contains a number of coefficients (to be determined by the fitting process) by using instead the notation \( f(x;c) \), where \( c \) denotes the vector of coefficients. An example of a nonlinear fitting function is

\[ f(x;c) = c_1 + c_2 \exp(-c_4 x) + c_3 \exp(-c_5 x), \quad (16) \]

which is in one variable and contains five coefficients. Note that here, as elsewhere in this Chapter Introduction, we use the term 'coefficients' to include all the quantities whose values are to be determined by the fitting process, not just those which occur linearly. We may observe that it is only the presence of the coefficients \( c_4 \) and \( c_5 \) which makes the form (16) nonlinear.

If the values of these two coefficients were known beforehand, (16) would instead be a linear function which, in terms of the general linear form (15), has \( p=3 \) and

\[ (\phi_1(x)) = 1, \quad (\phi_2(x)) = \exp(-c_4 x), \quad \text{and} \quad (\phi_3(x)) = \exp(-c_5 x). \]

We may note also that polynomials and splines, such as (9) and (14), are themselves linear in their coefficients. Thus if, when
fitting with these functions, a suitable special routine is not available (as when more than two independent variables are involved or when fitting in the $l_1$ norm), it is appropriate to use a routine designed for a general linear function.

2.5. Constrained Problems

So far, we have considered only fitting processes in which the values of the coefficients in the fitting function are determined by an unconstrained minimization of a particular norm. Some fitting problems, however, require that further restrictions be placed on the determination of the coefficient values. Sometimes these restrictions are contained explicitly in the formulation of the problem in the form of equalities or inequalities which the coefficients, or some function of them, must satisfy. For example, if the fitting function contains a term $A \exp(-kx)$, it may be required that $k \geq 0$. Often, however, the equality or inequality constraints relate to the value of the fitting function or its derivatives at specified values of the independent variable(s), but these too can be expressed in terms of the coefficients of the fitting function, and it is appropriate to do this if a general linear or nonlinear routine is being used. For example, if the fitting function is that given in (10), the requirement that the first derivative of the function at $x=x_0$ be non-negative can be expressed as

$$c_1 N_1'(x_0) + c_2 N_2'(x_0) + \ldots + c_p N_p'(x_0) \geq 0, \quad (17)$$

where the prime denotes differentiation with respect to $x$ and each derivative is evaluated at $x=x_0$. On the other hand, if the requirement had been that the derivative at $x=x_0$ be exactly zero, the inequality sign in (17) would be replaced by an equality.

Routines which provide a facility for minimizing the appropriate norm subject to such constraints are discussed in Section 3.6.

2.6. References

(For definition of normalised B-splines and details of numerical methods.)

3. Recommendations on Choice and Use of Routines

3.1. General

The choice of a routine to treat a particular fitting problem will depend first of all on the fitting function and the norm to be used. Unless there is good reason to the contrary, the fitting function should be a polynomial or a cubic spline (in the appropriate number of variables) and the norm should be the $l_2$ norm (leading to the least-squares fit). If some other function is to be used, the choice of routine will depend on whether the function is nonlinear (in which case see Section 3.5.2) or linear in its coefficients (see Section 3.5.1), and, in the latter case, on whether the $l_1$ or $l_2$ norm is to be used. The latter section is appropriate for polynomials and splines, too, if the $l_1$ norm is preferred.

In the case of a polynomial or cubic spline, if there is only one independent variable, the user should choose a spline (Section 3.3) when the curve represented by the data is of complicated form, perhaps with several peaks and troughs. When the curve is of simple form, first try a polynomial (see Section 3.2) of low degree, say up to degree 5 or 6, and then a spline if the polynomial fails to provide a satisfactory fit. (Of course, if third-derivative discontinuities are unacceptable to the user, a polynomial is the only choice.) If the problem is one of surface fitting, one of the spline routines should be used (Section 3.4). If the problem has more than two independent variables, it may be treated by the general linear routine in Section 3.5.1, again using a polynomial in the first instance.

Another factor which affects the choice of routine is the presence of constraints, as previously discussed in Section 2.5. Indeed this factor is likely to be overriding at present, because of the limited number of routines which have the necessary facility. See Section 3.6.
3.1.1. Data considerations

A satisfactory fit cannot be expected by any means if the number and arrangement of the data points do not adequately represent the character of the underlying relationship: sharp changes in behaviour, in particular, such as sharp peaks, should be well covered. Data points should extend over the whole range of interest of the independent variable(s): extrapolation outside the data ranges is most unwise. Then, with polynomials, it is advantageous to have additional points near the ends of the ranges, to counteract the tendency of polynomials to develop fluctuations in these regions. When, with polynomial curves, the user can precisely choose the x-values of the data, the special points defined in Section 3.2.2 should be selected. With splines the choice is less critical as long as the character of the relationship is adequately represented. All fits should be tested graphically before accepting them as satisfactory.

For this purpose it should be noted that it is not sufficient to plot the values of the fitted function only at the data values of the independent variable(s); at the least, its values at a similar number of intermediate points should also be plotted, as unwanted fluctuations may otherwise go undetected. Such fluctuations are the less likely to occur the lower the number of coefficients chosen in the fitting function. No firm guide can be given, but as a rough rule, at least initially, the number of coefficients should not exceed half the number of data points (points with equal or nearly equal values of the independent variable, or both independent variables in surface fitting, counting as a single point for this purpose). However, the situation may be such, particularly with a small number of data points, that a satisfactorily close fit to the data cannot be achieved without unwanted fluctuations occurring. In such cases, it is often possible to improve the situation by a transformation of one or more of the variables, as discussed in the next paragraph: otherwise it will be necessary to provide extra data points. Further advice on curve fitting is given in Cox and Hayes [1] and, for polynomials only, in Hayes [3] of Section 2.7. Much of the advice applies also to surface fitting; see also the Routine Documents.

3.1.2. Transformation of variables

Before starting the fitting, consideration should be given to the choice of a good form in which to deal with each of the variables: often it will be satisfactory to use the variables as they stand, but sometimes the use of the logarithm, square root, or some other function of a variable will lead to a better-behaved relationship. This question is customarily taken into
account in preparing graphs and tables of a relationship and the same considerations apply when curve or surface fitting. The practical context will often give a guide. In general, it is best to avoid having to deal with a relationship whose behaviour in one region is radically different from that in another. A steep rise at the left-hand end of a curve, for example, can often best be treated by curve fitting in terms of \( \log(x+c) \) with some suitable value of the constant \( c \). A case when such a transformation gave substantial benefit is discussed in Hayes [3] page 60. According to the features exhibited in any particular case, transformation of either dependent variable or independent variable(s) or both may be beneficial. When there is a choice it is usually better to transform the independent variable(s): if the dependent variable is transformed, the weights attached to the data points must be adjusted. Thus (denoting the dependent variable by \( y \), as in the notation for curves) if the \( y \) to be fitted have been obtained by a transformation \( y=g(Y) \) from original data values \( Y \), with weights \( W \), for \( r=1,2,...,m \), we must take

\[
\hat{w} = W / (d_y/dY),
\]

where the derivative is evaluated at \( Y \). Strictly, the transformation of \( Y \) and the adjustment of weights are valid only when the data errors in the \( Y \) are small compared with the range spanned by the \( Y \), but this is usually the case.

3.2. Polynomial Curves

3.2.1. Least-squares polynomials: arbitrary data points

E02ADF fits to arbitrary data points, with arbitrary weights, polynomials of all degrees up to a maximum degree \( k \), which is at choice. If the user is seeking only a low degree polynomial, up to degree 5 or 6 say, \( k=10 \) is an appropriate value, providing there are about 20 data points or more. To assist in deciding the degree of polynomial which satisfactorily fits the data, the routine provides the root-mean-square-residuals \( s_i \) for all degrees \( i=1,2,...,k \). In a satisfactory case, these \( s_i \) will decrease steadily as \( i \) increases and then settle down to a fairly constant value, as shown in the example.
If the s values settle down in this way, it indicates that the closest polynomial approximation justified by the data has been achieved. The degree which first gives the approximately constant value of s (degree 5 in the example) is the appropriate degree to select. (Users who are prepared to accept a fit higher than sixth degree, should simply find a high enough value of k to enable the type of behaviour indicated by the example to be detected: thus they should seek values of k for which at least 4 or 5 consecutive values of s are approximately the same.) If the degree were allowed to go high enough, s would, in most cases, eventually start to decrease again, indicating that the data points are being fitted too closely and that undesirable fluctuations are developing between the points. In some cases, particularly with a small number of data points, this final decrease is not distinguishable from the initial decrease in s.

In such cases, users may seek an acceptable fit by examining the graphs of several of the polynomials obtained. Failing this, they may (a) seek a transformation of variables which improves the behaviour, (b) try fitting a spline, or (c) provide more data points. If data can be provided simply by drawing an
approximating curve by hand and reading points from it, use the points discussed in Section 3.2.2.

3.2.2. Least-squares polynomials: selected data points

When users are at liberty to choose the $x$-values of data points, such as when the points are taken from a graph, it is most advantageous when fitting with polynomials to use the values $x = \cos((\pi)r/n)$, for $r=0,1,\ldots,n$ for some value of $n$, a suitable value for which is discussed at the end of this section. Note that these $x$ relate to the variable $x$ after it has been normalised so that its range of interest is -1 to +1. E02ADF may then be used as in Section 3.2.1 to seek a satisfactory fit.

3.3. Cubic Spline Curves

3.3.1. Least-squares cubic splines

E02BAF fits to arbitrary data points, with arbitrary weights, a cubic spline with interior knots specified by the user. The choice of these knots so as to give an acceptable fit must largely be a matter of trial and error, though with a little experience a satisfactory choice can often be made after one or two trials. It is usually best to start with a small number of knots (too many will result in unwanted fluctuations in the fit, or even in there being no unique solution) and, examining the fit graphically at each stage, to add a few knots at a time at places where the fit is particularly poor. Moving the existing knots towards these places will also often improve the fit. In regions where the behaviour of the curve underlying the data is changing rapidly, closer knots will be needed than elsewhere. Otherwise, positioning is not usually very critical and equally-spaced knots are often satisfactory. See also the next section, however.

A useful feature of the routine is that it can be used in applications which require the continuity to be less than the normal continuity of the cubic spline. For example, the fit may be required to have a discontinuous slope at some point in the range. This can be achieved by placing three coincident knots at the given point. Similarly a discontinuity in the second derivative at a point can be achieved by placing two knots there. Analogy with these discontinuous cases can provide guidance in more usual cases: for example, just as three coincident knots can produce a discontinuity in slope, so three close knots can produce a rapid change in slope. The closer the knots are, the more rapid can the change be.

Figure 1
An example set of data is given in Figure 1. It is a rather tricky set, because of the scarcity of data on the right, but it will serve to illustrate some of the above points and to show some of the dangers to be avoided. Three interior knots (indicated by the vertical lines at the top of the diagram) are chosen as a start. We see that the resulting curve is not steep enough in the middle and fluctuates at both ends, severely on the right. The spline is unable to cope with the shape and more knots are needed.

In Figure 2, three knots have been added in the centre, where the data shows a rapid change in behaviour, and one further out at each end, where the fit is poor. The fit is still poor, so a further knot is added in this region and, in Figure 3, disaster ensues in rather spectacular fashion.

The reason is that, at the right-hand end, the fits in Figure 1 and Figure 2 have been interpreted as poor simply because of the fluctuations about the curve underlying the data (or what it is naturally assumed to be). But the fitting process knows only about the data and nothing else about the underlying curve, so it is important to consider only closeness to the data when deciding goodness of fit.

Thus, in Figure 1, the curve fits the last two data points quite well compared with the fit elsewhere, so no knot should have been added in this region. In Figure 2, the curve goes exactly through the last two points, so a further knot is certainly not needed here.

Figure 4
Please see figure in printed Reference Manual

Figure 4 shows what can be achieved without the extra knot on each of the flat regions. Remembering that within each knot interval the spline is a cubic polynomial, there is really no need to have more than one knot interval covering each flat region.

What we have, in fact, in Figure 2 and Figure 3 is a case of too many knots (so too many coefficients in the spline equation) for
the number of data points. The warning in the second paragraph of
Section 2.1 was that the fit will then be too close to the data,
tending to have unwanted fluctuations between the data points.
The warning applies locally for splines, in the sense that, in
localities where there are plenty of data points, there can be a
lot of knots, as long as there are few knots where there are few
points, especially near the ends of the interval. In the present
element, with so few data points on the right, just the one extra
knot in Figure 2 is too many! The signs are clearly present, with
the last two points fitted exactly (at least to the graphical
accuracy and actually much closer than that) and fluctuations
within the last two knot-intervals (cf. Figure 1, where only the
final point is fitted exactly and one of the wobbles spans
several data points).

The situation in Figure 3 is different. The fit, if computed
exactly, would still pass through the last two data points, with
even more violent fluctuations. However, the problem has become
so ill-conditioned that all accuracy has been lost. Indeed, if
the last interior knot were moved a tiny amount to the right,
there would be no unique solution and an error message would have
been caused. Near-singularity is, sadly, not picked up by the
routine, but can be spotted readily in a graph, as Figure 3. B-
spline coefficients becoming large, with alternating signs, is
another indication. However, it is better to avoid such
situations, firstly by providing, whenever possible, data
adequately covering the range of interest, and secondly by
placing knots only where there is a reasonable amount of data.

The example here could, in fact, have utilised from the start the
observation made in the second paragraph of this section, that
three close knots can produce a rapid change in slope. The
example has two such rapid changes and so requires two sets of
three close knots (in fact, the two sets can be so close that one
knot can serve in both sets, so only five knots prove sufficient
in Figure 4). It should be noted, however, that the rapid turn
occurs within the range spanned by the three knots. This is the
reason that the six knots in Figure 2 are not satisfactory as they
do not quite span the two turns.

Some more examples to illustrate the choice of knots are given in
Cox and Hayes [1].

3.3.2. Automatic fitting with cubic splines

E02BEF also fits cubic splines to arbitrary data points with
arbitrary weights but itself chooses the number and positions of
the knots. The user has to supply only a threshold for the sum of
squares of residuals. The routine first builds up a knot set by a
series of trial fits in the l norm. Then, with the knot set
decided, the final spline is computed to minimize a certain smoothing measure subject to satisfaction of the chosen threshold. Thus it is easier to use than E02BAF (see previous section), requiring only some experimentation with this threshold. It should therefore be first choice unless the user has a preference for the ordinary least-squares fit or, for example, wishes to experiment with knot positions, trying to keep their number down (E02BEF aims only to be reasonably frugal with knots).

3.4. Spline Surfaces

3.4.1. Least-squares bicubic splines

E02DAF fits to arbitrary data points, with arbitrary weights, a bicubic spline with its two sets of interior knots specified by the user. For choosing these knots, the advice given for cubic splines, in Section 3.3.1 above, applies here too. (See also the next section, however.) If changes in the behaviour of the surface underlying the data are more marked in the direction of one variable than of the other, more knots will be needed for the former variable than the latter. Note also that, in the surface case, the reduction in continuity caused by coincident knots will extend across the whole spline surface: for example, if three knots associated with the variable x are chosen to coincide at a value L, the spline surface will have a discontinuous slope across the whole extent of the line x=L.

With some sets of data and some choices of knots, the least-squares bicubic spline will not be unique. This will not occur, with a reasonable choice of knots, if the rectangle R is well covered with data points: here R is defined as the smallest rectangle in the (x,y) plane, with sides parallel to the axes, which contains all the data points. Where the least-squares solution is not unique, the minimal least-squares solution is computed, namely that least-squares solution which has the smallest value of the sum of squares of the B-spline coefficients c (see the end of Section 2.3.2 above). This choice of least-squares solution tends to minimize the risk of unwanted fluctuations in the fit. The fit will not be reliable, however, in regions where there are few or no data points.

3.4.2. Automatic fitting with bicubic splines

E02DDF also fits bicubic splines to arbitrary data points with arbitrary weights but chooses the knot sets itself. The user has to supply only a threshold for the sum of squares of residuals. Just like the automatic curve E02BEF (Section 3.3.2), E02DDF then
builds up the knot sets and finally fits a spline minimizing a smoothing measure subject to satisfaction of the threshold. Again, this easier to use routine is normally to be preferred, at least in the first instance.

E02DCF is a very similar routine to E02DDF but deals with data points of equal weight which lie on a rectangular mesh in the (x,y) plane. This kind of data allows a very much faster computation and so is to be preferred when applicable. Substantial departures from equal weighting can be ignored if the user is not concerned with statistical questions, though the quality of the fit will suffer if this is taken too far. In such cases, the user should revert to E02DDF.

3.5. General Linear and Nonlinear Fitting Functions

3.5.1. General linear functions

For the general linear function (15), routines are available for fitting in the 1 and 2 norms. The least-squares routines (which are to be preferred unless there is good reason to use another norm -- see Section 2.1.1) are in Chapter F04. The 1 routine is E02GAF.

All the above routines are essentially linear algebra routines, and in considering their use we need to view the fitting process in a slightly different way from hitherto. Taking y to be the dependent variable and x the vector of independent variables, we have, as for equation (1) but with each x now a vector, 

$$
(\epsilon_r) = y - f(x_r) \quad r=1,2,\ldots,m.
$$

Substituting for f(x) the general linear form (15), we can write this as

$$
c_1(\phi_1)(x_r) + c_2(\phi_2)(x_r) + \ldots + c_p(\phi_p)(x_r) = y_r - (\epsilon_r),
$$

$$
r=1,2,\ldots,m
$$

Thus we have a system of linear equations in the coefficients c .

Usually, in writing these equations, the (\epsilon_r) are omitted and simply taken as implied. The system of equations is then described as an overdetermined system (since we must have m > p if
there is to be the possibility of a unique solution to our fitting problem), and the fitting process of computing the $c_j$ to minimize one or other of the norms (2), (3) and (4) can be described, in relation to the system of equations, as solving the overdetermined system in that particular norm. In matrix notation, the system can be written as

$$(\Phi)c=y,$$ (20)

where $(\Phi)$ is the $m$ by $p$ matrix whose element in row $r$ and column $j$ is $(\phi_j(x_r)$, for $r=1,2,...,m$; $j=1,2,...,p$. The vectors $c$ and $y$ respectively contain the coefficients $c_j$ and the data values $y_r$.

The routines, however, use the standard notation of linear algebra, the overdetermined system of equations being denoted by

$$A\mathbf{x} = \mathbf{b}$$ (21)

The correspondence between this notation and that which we have used for the data-fitting problem (equation (20)) is therefore given by

$$A=(\Phi),\quad \mathbf{x}=c\quad \mathbf{b}=y$$ (22)

Note that the norms used by these routines are the unweighted norms (2) and (3). If the user wishes to apply weights to the data points, that is to use the norms (5) or (6), the equivalences (22) should be replaced by

$$A=D(\Phi),\quad \mathbf{x}=c\quad \mathbf{b}=Dy$$

where $D$ is a diagonal matrix with $w_r$ as the $r$th diagonal element.

Here $w_r$, for $r=1,2,...,m$, is the weight of the $r$th data point as defined in Section 2.1.2.

3.5.2. Nonlinear functions

Routines for fitting with a nonlinear function in the $l^2$ norm are provided in Chapter E04, and that chapter’s Introduction should be consulted for the appropriate choice of routine. Again, however, the notation adopted is different from that we have used for data fitting. In the latter, we denote the fitting function
by \( f(x;c) \), where \( x \) is the vector of independent variables and \( c \) is the vector of coefficients, whose values are to be determined. The squared 1 norm, to be minimized with respect to the elements of \( c \), is then

\[
\sum_{r=1}^{m} w[y - f(x;c)]^2
\]

where \( y \) is the \( r \)th data value of the dependent variable, \( x \) is the vector containing the \( r \)th values of the independent variables, and \( w \) is the corresponding weight as defined in Section 2.1.2.

On the other hand, in the nonlinear least-squares routines of Chapter E04, the function to be minimized is denoted by

\[
\sum_{i=1}^{m} f(x)^2
\]

the minimization being carried out with respect to the elements of the vector \( x \). The correspondence between the two notations is given by

\[ x = c \text{ and } f(x) = w[y - f(x;c)], \quad i=r=1,2,\ldots,m. \]

Note especially that the vector \( x \) of variables of the nonlinear least-squares routines is the vector \( c \) of coefficients of the data-fitting problem, and in particular that, if the selected routine requires derivatives of the \( f(x) \) to be provided, these are derivatives of \( w[y - f(x;c)] \) with respect to the coefficients of the data-fitting problem.

3.6. Constraints

At present, there are only a limited number of routines which fit subject to constraints. Chapter E04 contains a routine, E04UCF,
which can be used for fitting with a nonlinear function in the $l^2$ norm subject to equality or inequality constraints. This routine, unlike those in that chapter suited to the unconstrained case, is not designed specifically for minimizing functions which are sums of squares, and so the function (23) has to be treated as a general nonlinear function. The E04 Chapter Introduction should be consulted.

The remaining constraint routine relates to fitting with polynomials in the $l^2$ norm. E02AGF deals with polynomial curves and allows precise values of the fitting function and (if required) all its derivatives up to a given order to be prescribed at one or more values of the independent variable.

3.7. Evaluation, Differentiation and Integration

Routines are available to evaluate, differentiate and integrate polynomials in Chebyshev-series form and cubic or bicubic splines in B-spline form. These polynomials and splines may have been produced by the various fitting routines or, in the case of polynomials, from prior calls of the differentiation and integration routines themselves.

E02AEF and E02AKF evaluate polynomial curves: the latter has a longer parameter list but does not require the user to normalise the values of the independent variable and can accept coefficients which are not stored in contiguous locations. E02BBF evaluates cubic spline curves, and E02DEF and E02DFF bicubic spline surfaces.

Differentiation and integration of polynomial curves are carried out by E02AHF and E02AJF respectively. The results are provided in Chebyshev-series form and so repeated differentiation and integration are catered for. Values of the derivative or integral can then be computed using the appropriate evaluation routine.

For splines the differentiation and integration routines provided are of a different nature from those for polynomials. E02BCF provides values of a cubic spline curve and its first three derivatives (the rest, of course, are zero) at a given value of $x$ spline over its whole range. These routines can also be applied to surfaces of the form (14). For example, if, for each value of $j$ in turn, the coefficients $c_{ij}$, for $i=1,2,\ldots,p$ are supplied to E02BCF with $x=x_j$ and on each occasion we select from the output the value of the second derivative, $d_{ij}$ say, and if the whole set
of d are then supplied to the same routine with x=y, the output
will contain all the values at (x ,y ) of
0 0

\[ \begin{array}{ccc}
2 & r+2 & \\
\frac{d^2 f}{dx^2} & \frac{d f}{dx} & \\
\end{array} \]
\[ \begin{array}{ccc}
\frac{dd f}{ddx} & \frac{dd f}{ddy} & \\
\frac{2}{2} & r & \\
\frac{dd f}{ddx} & \frac{dd f}{ddy} & \\
\end{array} \]

Equally, if after each of the first p calls of E02BCF we had
selected the function value (E02BBF would also provide this)
instead of the second derivative and we had supplied these values
to E02BDF, the result obtained would have been the value of

\[ \frac{B}{A} \int f(x ,y)dy, \]
\[ / 0 \]

where A and B are the end-points of the y interval over which the
spline was defined.

Least-squares polynomial approximations

--- nage.ht ---

E02ADF(3NAG) Foundation Library (12/10/92) E02ADF(3NAG)

E02 -- Curve and Surface Fitting
E02ADF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E02ADF computes weighted least-squares polynomial approximations to an arbitrary set of data points.

2. Specification

**SUBROUTINE** E02ADF (M, KPLUS1, NROWS, X, Y, W, WORK1, WORK2, A, S, IFAIL)
3. Description

This routine determines least-squares polynomial approximations of degrees 0,1,...,k to the set of data points \((x_r, y_r)\) with weights \(w_r\), for \(r=1,2,...,m\).

The approximation of degree \(i\) has the property that it minimizes (sigma) the sum of squares of the weighted residuals \((\epsilon_r)\),

\[
(\epsilon_r) = w_r (y_r - f_r)
\]

where

\[
and \(f_r\) is the value of the polynomial of degree \(i\) at the \(r\)th data point.

Each polynomial is represented in Chebyshev-series form with

normalised argument \(x\). This argument lies in the range \(-1\) to \(+1\) and is related to the original variable \(x\) by the linear transformation

\[
(2x - x_{\text{max}} - x_{\text{min}})
\]

\[
x = \frac{\max - \min}{\max - \min}
\]

\[
(x - x_{\text{min}})
\]

Here \(x_{\text{max}}\) and \(x_{\text{min}}\) are respectively the largest and smallest values of \(x\). The polynomial approximation of degree \(i\) is represented as

\[
1 -a T_{i+1,1} + T_{i+1,2} + T_{i+1,3} + \cdots + T_{i+1,i+1} x
\]

where \(T_{i,j}(x)\) is the Chebyshev polynomial of the first kind of
degree \( j \) with argument \( x \).

For \( i=0,1,\ldots,k \), the routine produces the values of \( a \), for \( i+1, j+1 \) \( j=0,1,\ldots,i \), together with the value of the root mean square

\[
\text{residual } s = \frac{1}{\sqrt{i}} \text{(sigma)}
\]

In the case \( m=i+1 \) the routine sets \( s = 0 \).

The method employed is due to Forsythe [4] and is based upon the generation of a set of polynomials orthogonal with respect to summation over the normalised data set. The extensions due to Clenshaw [1] to represent these polynomials as well as the approximating polynomials in their Chebyshev-series forms are incorporated. The modifications suggested by Reinsch and Gentleman (see [5]) to the method originally employed by Clenshaw for evaluating the orthogonal polynomials from their Chebyshev-series representations are used to give greater numerical stability.

For further details of the algorithm and its use see Cox [2] and [3].

Subsequent evaluation of the Chebyshev-series representations of the polynomial approximations should be carried out using E02AEF.

4. References

5. Parameters

1: M -- INTEGER
   Input
   On entry: the number m of data points. Constraint: M ≥MDIST ≥2, where MDIST is the number of distinct x values in the data.

2: KPLUS1 -- INTEGER
   Input
   On entry: k+1, where k is the maximum degree required.
   Constraint: 0 < KPLUS1 ≤ MDIST, where MDIST is the number of distinct x values in the data.

3: NROWS -- INTEGER
   Input
   On entry: the first dimension of the array A as declared in the (sub)program from which E02ADF is called.
   Constraint: NROWS ≥ KPLUS1.

4: X(M) -- DOUBLE PRECISION array
   Input
   On entry: the values x of the independent variable, for
   r
   r=1,2,...,m. Constraint: the values must be supplied in non-decreasing order with X(M) > X(1).

5: Y(M) -- DOUBLE PRECISION array
   Input
   On entry: the values y of the dependent variable, for
   r
   r=1,2,...,m.

6: W(M) -- DOUBLE PRECISION array
   Input
   On entry: the set of weights, w, for r=1,2,...,m. For
   r
   advice on the choice of weights, see Section 2.1.2 of the Chapter Introduction. Constraint: W(r) > 0.0, for r=1,2,...,m.

7: WORK1(3*M) -- DOUBLE PRECISION array
   Workspace

8: WORK2(2*KPLUS1) -- DOUBLE PRECISION array
   Workspace

9: A(NROWS,KPLUS1) -- DOUBLE PRECISION array
   Output
On exit: the coefficients of $T(x)$ in the approximating polynomial of degree $i$. $A(i+1,j+1)$ contains the coefficient $a_{i+1,j+1}$, for $i=0,1,...,k$; $j=0,1,...,i$.

10: S(KPLUS1) -- DOUBLE PRECISION array Output
On exit: $S(i+1)$ contains the root mean square residual $s_i$ for $i=0,1,...,k$, as described in Section 3. For the interpretation of the values of the $s_i$ and their use in selecting an appropriate degree, see Section 3.1 of the Chapter Introduction.

11: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings
Errors detected by the routine:

IFAIL= 1
The weights are not all strictly positive.

IFAIL= 2
The values of $X(r)$, for $r=1,2,...,M$ are not in non-decreasing order.

IFAIL= 3
All $X(r)$ have the same value: thus the normalisation of $X$ is not possible.

IFAIL= 4
On entry $KPLUS1 < 1$ (so the maximum degree required is negative)
or $KPLUS1 > MDIST$, where MDIST is the number of distinct $x$ values in the data (so there cannot be a unique solution for degree $k=KPLUS1-1$).

IFAIL= 5
$NROWS < KPLUS1$. 

7. Accuracy

No error analysis for the method has been published. Practical experience with the method, however, is generally extremely satisfactory.

8. Further Comments

The time taken by the routine is approximately proportional to $m(k+1)(k+1)$. The approximating polynomials may exhibit undesirable oscillations (particularly near the ends of the range) if the maximum degree $k$ exceeds a critical value which depends on the number of data points $m$ and their relative positions. As a rough guide, for equally-spaced data, this critical value is about $2\sqrt{m}$. For further details see Hayes [6] page 60.

9. Example

Determine weighted least-squares polynomial approximations of degrees 0, 1, 2 and 3 to a set of 11 prescribed data points. For the approximation of degree 3, tabulate the data and the corresponding values of the approximating polynomial, together with the residual errors, and also the values of the approximating polynomial at points half-way between each pair of adjacent data points.

The example program supplied is written in a general form that will enable polynomial approximations of degrees 0, 1, ..., $k$ to be obtained to $m$ data points, with arbitrary positive weights, and the approximation of degree $k$ to be tabulated. E02AEF is used to evaluate the approximating polynomial. The program is self-starting in that any number of data sets can be supplied.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
Evaluate polynomial from Chebyshev-series representation

— nage.ht —

\begin{page}{manpageXXe02aef}{NAG Documentation: e02aef}
\beginscroll
\begin{verbatim}
E02AEF(3NAG) Foundation Library (12/10/92) E02AEF(3NAG)

E02AEF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E02AEF evaluates a polynomial from its Chebyshev-series representation.

2. Specification

SUBROUTINE E02AEF (NPLUS1, A, XCAP, P, IFAIL)
INTEGER NPLUS1, IFAIL
DOUBLE PRECISION A(NPLUS1), XCAP, P

3. Description

This routine evaluates the polynomial

\[ 1 -a_1 T_0(x) + a_2 T_1(x) + a_3 T_2(x) + \ldots + a_{n+1} T_n(x) \]

for any value of \( x \) satisfying \(-1 \leq x \leq 1\). Here \( T_j(x) \) denotes the Chebyshev polynomial of the first kind of degree \( j \) with argument \( x \). The value of \( n \) is prescribed by the user.
In practice, the variable $x$ will usually have been obtained from an original variable $x$, where $x \leq x \leq x$ and

$$\frac{((x - x) - (x - x))}{x} = \frac{\min}{\max} \frac{(x - x)}{\max}$$

Note that this form of the transformation should be used computationally rather than the mathematical equivalent

$$\frac{(2x - x)}{x} = \frac{\min}{\max} \frac{(x - x)}{\max}$$

since the former guarantees that the computed value of $x$ differs from its true value by at most $4(\epsilon)$, where $\epsilon$ is the machine precision, whereas the latter has no such guarantee.

The method employed is based upon the three-term recurrence relation due to Clenshaw [1], with modifications to give greater numerical stability due to Reinsch and Gentleman (see [4]).

For further details of the algorithm and its use see Cox [2] and [3].

4. References

5. Parameters

1: NPLUS1 -- INTEGER
   Input
   On entry: the number n+1 of terms in the series (i.e., one
   greater than the degree of the polynomial). Constraint:
   NPLUS1 >= 1.

2: A(NPLUS1) -- DOUBLE PRECISION array
   Input
   On entry: A(i) must be set to the value of the ith
   coefficient in the series, for i=1,2,...,n+1.

3: XCAP -- DOUBLE PRECISION
   Input
   On entry: x, the argument at which the polynomial is to be
   evaluated. It should lie in the range -1 to +1, but a value
   just outside this range is permitted (see Section 6) to
   allow for possible rounding errors committed in the
   transformation from x to x discussed in Section 3. Provided
   the recommended form of the transformation is used, a
   successful exit is thus assured whenever the value of x lies
   in the range x to x.
   min max

4: P -- DOUBLE PRECISION
   Output
   On exit: the value of the polynomial.

5: IFAIL -- INTEGER
   Input/Output
   On entry: IFAIL must be set to 0, -1 or 1. For users not
   familiar with this parameter (described in the Essential
   Introduction) the recommended value is 0.
   On exit: IFAIL = 0 unless the routine detects an error (see
   Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
   ABS(XCAP) > 1.0 + 4(epsilon), where (epsilon) is the
   machine precision. In this case the value of P is set
   arbitrarily to zero.

IFAIL= 2
   On entry NPLUS1 < 1.
7. Accuracy

The rounding errors committed are such that the computed value of the polynomial is exact for a slightly perturbed set of coefficients \( a + (\delta a) \). The ratio of the sum of the absolute \( a \) values of the \( (\delta a) \) to the sum of the absolute values of the \( a \) is less than a small multiple of \((n+1)\) times machine precision.

8. Further Comments

The time taken by the routine is approximately proportional to \( n+1 \).

It is expected that a common use of E02AEF will be the evaluation of the polynomial approximations produced by E02ADF and E02AFF(*).

9. Example

Evaluate at 11 equally-spaced points in the interval \(-1 \leq x \leq 1\) the polynomial of degree 4 with Chebyshev coefficients, 2.0, 0.5, 0.25, 0.125, 0.0625.

The example program is written in a general form that will enable a polynomial of degree \( n \) in its Chebyshev-series form to be

evaluated at \( m \) equally-spaced points in the interval \(-1 \leq x \leq 1\). The program is self-starting in that any number of data sets can be supplied.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
Constrained weighted least-squares polynomial

--- nage.ht ---

\begin{verbatim}
E02AGF(3NAG) Foundation Library (12/10/92) E02AGF(3NAG)

E02 -- Curve and Surface Fitting
E02AGF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E02AGF computes constrained weighted least-squares polynomial approximations in Chebyshev-series form to an arbitrary set of data points. The values of the approximations and any number of their derivatives can be specified at selected points.

2. Specification

SUBROUTINE E02AGF (M, KPLUS1, NROWS, XMIN, XMAX, X, Y, W, MF, XF, YF, LYF, IP, A, S, NP1, WRK, LWRK, IWRK, LIWRK, IFAIL)

INTEGER M, KPLUS1, NROWS, MF, LYF, IP(MF), NP1, LWRK, IWRK(LIWRK), LIWRK, IFAIL
DOUBLE PRECISION XMIN, XMAX, X(M), Y(M), W(M), XF(MF), YF(LYF), A(NROWS,KPLUS1), S(KPLUS1), WRK(LWRK)

3. Description

This routine determines least-squares polynomial approximations of degrees up to k to the set of data points \((x_r, y_r)\) with weights \(w_r\), for \(r=1,2,\ldots,m\). The value of \(k\), the maximum degree required, is prescribed by the user. At each of the values \(x_f,\) for \(r = 1,2,\ldots,m\).
of the independent variable $x$, the approximations and their derivatives up to order $p$ are constrained to have one of

$$
\text{the user-specified values } Y_F, \text{ for } s=1,2,\ldots,n, \text{ where } n=MF+\geq p
$$

$$
\text{r} = 1
$$

The approximation of degree $i$ has the property that, subject to the imposed constraints, it minimizes (Sigma), the sum of the squares of the weighted residuals ($\epsilon_r$) for $r=1,2,\ldots,m$

$$
\epsilon_r = w_r (y - f_r (x))
$$

where

$$
(f_r (x)) = \text{the value of the polynomial approximation of degree } i \text{ at the } r\text{th data point.}
$$

Each polynomial is represented in Chebyshev-series form with normalised argument $x$. This argument lies in the range -1 to +1 and is related to the original variable $x$ by the linear transformation

$$
2x - (x_{\max} + x_{\min})
$$

$$
x = \frac{2x - (x_{\max} + x_{\min})}{(x_{\max} - x_{\min})}
$$

where $x_{\min}$ and $x_{\max}$, specified by the user, are respectively the lower and upper end-points of the interval of $x$ over which the polynomials are to be defined.

The polynomial approximation of degree $i$ can be written as

$$
1
$$

$$
-a +a T(x) + \ldots + a T(x) + \ldots + a T(x)
$$

$$
2 i,0 \quad i,1 \quad i,2 \quad \ldots \quad i, j \quad i, j \quad i, i
$$

where $T(x)$ is the Chebyshev polynomial of the first kind of
degree \( j \) with argument \( x \). For \( i=n, n+1, \ldots, k \), the routine produces the values of the coefficients \( a_{ij} \), for \( j=0, 1, \ldots, i \), together with the value of the root mean square residual, \( S_i \), defined as

\[
\sqrt{\frac{\sum_{j=m'+n-i-1}^{m'} (y_j - \hat{y}_j)^2}{m'+n-i-1}}
\]

where \( m' \) is the number of data points with non-zero weight.

Values of the approximations may subsequently be computed using E02AEF or E02AKF.

First E02AGF determines a polynomial \( (\mu)(x) \), of degree \( n-1 \), which satisfies the given constraints, and a polynomial \( (\nu)(x) \), of degree \( n \), which has value (or derivative) zero wherever a constrained value (or derivative) is specified. It then fits \( y - (\mu)(x) \), for \( r=1, 2, \ldots, m \) with polynomials of the required degree in \( x \) each with factor \( (\nu)(x) \). Finally the coefficients of \( (\mu)(x) \) are added to the coefficients of these fits to give the coefficients of the constrained polynomial approximations to the data points \( (x_r, y_r) \), for \( r=1, 2, \ldots, m \). The method employed is given in Hayes [3]: it is an extension of Forsythe’s orthogonal polynomials method [2] as modified by Clenshaw [1].

4. References

5. Parameters

1:  M -- INTEGER  
    On entry: the number m of data points to be fitted.  
    Constraint: M >= 1. 

2:  KPLUS1 -- INTEGER  
    On entry: k+1, where k is the maximum degree required.  
    Constraint: n+1<=KPLUS1<=m''+n, where n is the total number of constraints and m'' is the number of data points with non-zero weights and distinct abscissae which do not coincide with any of the XF(r). 

3:  NROWS -- INTEGER  
    On entry: the first dimension of the array A as declared in the (sub)program from which E02AGF is called.  
    Constraint: NROWS >= KPLUS1. 

4:  XMIN -- DOUBLE PRECISION  
    Input

5:  XMAX -- DOUBLE PRECISION  
    Input
    On entry: the lower and upper end-points, respectively, of the interval [x_min,x_max]. Unless there are specific reasons to the contrary, it is recommended that XMIN and XMAX be set respectively to the lowest and highest value among the x_r and XF(r). This avoids the danger of extrapolation provided there is a constraint point or data point with non-zero weight at each end-point. Constraint: XMAX > XMIN.

6:  X(M) -- DOUBLE PRECISION array  
    Input
    On entry: the value x_r of the independent variable at the r_th data point, for r=1,2,...,m. Constraint: the X(r) must be in non-decreasing order and satisfy XMIN <= X(r) <= XMAX.

7:  Y(M) -- DOUBLE PRECISION array  
    Input
    On entry: Y(r) must contain y_r, the value of the dependent variable at the r_th data point, for r=1,2,...,m.

8:  W(M) -- DOUBLE PRECISION array  
    Input
    On entry: the weights w_r to be applied to the data points
x, for \( r=1,2,\ldots,m \). For advice on the choice of weights see the Chapter Introduction. Negative weights are treated as positive. A zero weight causes the corresponding data point to be ignored. Zero weight should be given to any data point whose \( x \) and \( y \) values both coincide with those of a constraint (otherwise the denominators involved in the root-mean-square residuals \( s \) will be slightly in error).

\[ i \]

9: MF -- INTEGER
On entry: the number of values of the independent variable at which a constraint is specified. Constraint: \( MF \geq 1 \).

10: XF(MF) -- DOUBLE PRECISION array
On entry: the \( r \)th value of the independent variable at which a constraint is specified, for \( r = 1,2,\ldots,MF \).
Constraint: these values need not be ordered but must be distinct and satisfy \( XMIN \leq XF(r) \leq XMAX \).

11: YF(LYF) -- DOUBLE PRECISION array
On entry: the values which the approximating polynomials and their derivatives are required to take at the points specified in XF. For each value of \( XF(r) \), YF contains in successive elements the required value of the approximation, its first derivative, second derivative,\ldots, \( p \)th derivative, for \( r = 1,2,\ldots,MF \). Thus the value which the \( k \)th derivative of each approximation (\( k=0 \) referring to the approximation itself) is required to take at the point \( XF(r) \) must be contained in \( YF(s) \), where

\[ s=r+k*p +p +\ldots+p , \]

for \( k=0,1,\ldots,p \) and \( r = 1,2,\ldots,MF \). The derivatives are with respect to the user’s variable \( x \).

12: LYF -- INTEGER
On entry: the dimension of the array YF as declared in the (sub)program from which E02AGF is called.
Constraint: \( LYF \geq n \), where \( n = MF*p +p +\ldots+p \).

13: IP(MF) -- INTEGER array
On entry: \( IP(r) \) must contain \( p \), the order of the highest-order derivative specified at \( XF(r) \), for \( r = 1,2,\ldots,MF \). \( p =0 \) implies that the value of the approximation at \( XF(r) \) is
specified, but not that of any derivative. Constraint: \( IP(r) \geq 0 \), for \( r=1,2,\ldots,\text{MF} \).

14: \( \text{A(NROWS,KPLUS1)} \) -- DOUBLE PRECISION array Output
On exit: \( \text{A}(i+1,j+1) \) contains the coefficient \( a_{ij} \) in the approximating polynomial of degree \( i \), for \( i=n,n+1,\ldots,k; j=0,1,\ldots,i \).

15: \( \text{S(KPLUS1)} \) -- DOUBLE PRECISION array Output
On exit: \( S(i+1) \) contains \( s_i \), for \( i=n,n+1,\ldots,k \), the root-mean-square residual corresponding to the approximating polynomial of degree \( i \). In the case where the number of data points with non-zero weight is equal to \( k+1-n \), \( s_i \) is indeterminate: the routine sets it to zero. For the interpretation of the values of \( s_i \) and their use in selecting an appropriate degree, see Section 3.1 of the Chapter Introduction.

16: \( \text{NP1} \) -- INTEGER Output
On exit: \( n+1 \), where \( n \) is the total number of constraint conditions imposed: \( n=\text{MF}+\text{p}_1+\text{p}_2+\ldots+\text{p}_{\text{MF}} \).

17: \( \text{WRK(LWRK)} \) -- DOUBLE PRECISION array Output
On exit: \( \text{WRK} \) contains weighted residuals of the highest degree of fit determined \( (k) \). The residual at \( x \) is in element \( 2(n+1)+3(m+k+1)+r \), for \( r=1,2,\ldots,m \). The rest of the array is used as workspace.

18: \( \text{LWRK} \) -- INTEGER Input
On entry: the dimension of the array \( \text{WRK} \) as declared in the (sub)program from which \( \text{E02AGF} \) is called. Constraint: \( \text{LWRK} \geq \max(4\text{M}+3\text{KPLUS1}, 8n+5\text{IPMAX}+\text{MF}+10)+2n+2 \), where \( \text{IPMAX} = \max(IP(R)) \).

19: \( \text{IWRK(LIWRK)} \) -- INTEGER array Workspace

20: \( \text{LIWRK} \) -- INTEGER Input
On entry: the dimension of the array \( \text{IWRK} \) as declared in the (sub)program from which \( \text{E02AGF} \) is called. Constraint: \( \text{LIWRK} \geq 2\text{MF}+2 \).

21: \( \text{IFAIL} \) -- INTEGER Input/Output
On entry: \( \text{IFAIL} \) must be set to 0, -1 or 1. For users not
familiar with this parameter (described in the Essential
Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see
Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
On entry M < 1,
    or KPLUS1 < n + 1,
    or NROWS < KPLUS1,
    or MF < 1,
    or LYF < n,
    or LWRK is too small (see Section 5),
    or LIWRK<2*MF+2.
(Here n is the total number of constraint conditions.)

IFAIL= 2
IP(r) < 0 for some r = 1,2,...,MF.

IFAIL= 3
XMIN >= XMAX, or XF(r) is not in the interval XMIN to XMAX
for some r = 1,2,...,MF, or the XF(r) are not distinct.

IFAIL= 4
X(r) is not in the interval XMIN to XMAX for some
r=1,2,...,M.

IFAIL= 5
X(r) < X(r-1) for some r=2,3,...,M.

IFAIL= 6
KPLUS1>m''+n, where m'' is the number of data points with
non-zero weight and distinct abscissae which do not coincide
with any XF(r). Thus there is no unique solution.

IFAIL= 7
The polynomials (mu)(x) and/or (nu)(x) cannot be determined.
The problem supplied is too ill-conditioned. This may occur
when the constraint points are very close together, or large
in number, or when an attempt is made to constrain high-
order derivatives.

7. Accuracy

No complete error analysis exists for either the interpolating algorithm or the approximating algorithm. However, considerable experience with the approximating algorithm shows that it is generally extremely satisfactory. Also the moderate number of constraints, of low order, which are typical of data fitting applications, are unlikely to cause difficulty with the interpolating routine.

8. Further Comments

The time taken by the routine to form the interpolating polynomial is approximately proportional to $n^3$, and that to form the approximating polynomials is very approximately proportional to $m(k+1)(k+1-n)$.

To carry out a least-squares polynomial fit without constraints, use E02ADF. To carry out polynomial interpolation only, use E01AEF(*).

9. Example

The example program reads data in the following order, using the notation of the parameter list above:

\begin{verbatim}
MF
IP(i), XF(i), Y-value and derivative values (if any) at XF(i), for i= 1,2,...,MF
M
X(i), Y(i), W(i), for i=1,2,...,M
k, XMIN, XMAX
\end{verbatim}

The output is:

- the root-mean-square residual for each degree from $n$ to $k$;
- the Chebyshev coefficients for the fit of degree $k$;
- the data points, and the fitted values and residuals for the fit of degree $k$.

The program is written in a generalized form which will read any
number of data sets.

The data set supplied specifies 5 data points in the interval [0.0, 4.0] with unit weights, to which are to be fitted polynomials, p, of degrees up to 4, subject to the 3 constraints:

\[ p(0.0) = 1.0, \quad p'(0.0) = -2.0, \quad p(4.0) = 9.0. \]

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

\end{verbatim}

E02AHF(3NAG)  Foundation Library (12/10/92)  E02AHF(3NAG)

E02 -- Curve and Surface Fitting  E02AHF
E02AHF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E02AHF determines the coefficients in the Chebyshev-series representation of the derivative of a polynomial given in Chebyshev-series form.

2. Specification
3. Description

This routine forms the polynomial which is the derivative of a given polynomial. Both the original polynomial and its derivative are represented in Chebyshev-series form. Given the coefficients $a_i$, for $i=0,1,\ldots,n$, of a polynomial $p(x)$ of degree $n$, where

$$p(x) = -a_0 + a_1 T_1(x) + \ldots + a_n T_n(x)$$

the routine returns the coefficients $a_i$, for $i=0,1,\ldots,n-1$, of the polynomial $q(x)$ of degree $n-1$, where

$$q(x) = \frac{dp(x)}{dx} = -a_0 + a_1 T_1(x) + \ldots + a_{n-1} T_{n-1}(x).$$

Here $T_j(x)$ denotes the Chebyshev polynomial of the first kind of degree $j$ with argument $x$. It is assumed that the normalised variable $x$ in the interval $[-1,+1]$ was obtained from the user's original variable $x$ in the interval $[x_{\text{min}}, x_{\text{max}}]$ by the linear transformation

$$2x - (x_{\text{max}} + x_{\text{min}})$$

and that the user requires the derivative to be with respect to
the variable \( x \). If the derivative with respect to \( x \) is required, set \( x = 1 \) and \( x = -1 \).

\[
\begin{align*}
\max & \quad \min \\
\end{align*}
\]

Values of the derivative can subsequently be computed, from the coefficients obtained, by using E02AKF.

The method employed is that of [1] modified to obtain the derivative with respect to \( x \). Initially setting \( a = a = 0 \), the routine forms successively

\[
\begin{align*}
2 \\
\max & \quad \min \\
\end{align*}
\]

4. References

5. Parameters

1: NP1 -- INTEGER Input
   On entry: \( n+1 \), where \( n \) is the degree of the given polynomial \( p(x) \). Thus NP1 is the number of coefficients in this polynomial. Constraint: NP1 \( \geq 1 \).

2: XMIN -- DOUBLE PRECISION Input

3: XMAX -- DOUBLE PRECISION Input
   On entry: the lower and upper end-points respectively of the interval \([x_{\text{min}}, x_{\text{max}}]\). The Chebyshev-series representation is in terms of the normalised variable \( x \), where

\[
\begin{align*}
2x - (x + x) \\
\max & \quad \min \\
x = \frac{1}{x - x} \\
\max & \quad \min
\end{align*}
\]

Constraint: XMAX > XMIN.
4: A(LA) -- DOUBLE PRECISION array
   On entry: the Chebyshev coefficients of the polynomial p(x).
   Specifically, element 1 + i*IA1 of A must contain the
coefficient a_i for i=0,1,...,n. Only these n+1 elements
   will be accessed.

   Unchanged on exit, but see ADIF, below.

5: IA1 -- INTEGER
   On entry: the index increment of A. Most frequently the
   Chebyshev coefficients are stored in adjacent elements of A,
   and IA1 must be set to 1. However, if, for example, they are
   stored in A(1),A(4),A(7),..., then the value of IA1 must be
   3. See also Section 8. Constraint: IA1 >= 1.

6: LA -- INTEGER
   On entry:
   the dimension of the array A as declared in the (sub)program
   from which E02AHF is called.
   Constraint: LA>=1+(NP1-1)*IA1.

7: PATM1 -- DOUBLE PRECISION
   On exit: the value of p(x). If this value is passed to
   min
   the integration routine E02AJF with the coefficients of q(x)
   , then the original polynomial p(x) is recovered, including
   its constant coefficient.

8: ADIF(LADIF) -- DOUBLE PRECISION array
   On exit: the Chebyshev coefficients of the derived
   polynomial q(x). (The differentiation is with respect to the
   variable x). Specifically, element 1+i*IADIF1 of ADIF

   contains the coefficient a_i, i=0,1,...,n-1. Additionally
   element 1+n*IADIF1 is set to zero. A call of the routine may
   have the array name ADIF the same as A, provided that note
   is taken of the order in which elements are overwritten,
   when choosing the starting elements and increments IA1 and
   IADIF1: i.e., the coefficients a_0,a_1,...,a_i-1 must be intact
   after coefficient a_i is stored. In particular, it is
   possible to overwrite the a_i completely by having IA1 =
   i
   IADIF1, and the actual arrays for A and ADIF identical.
9: IADIF1 -- INTEGER
   On entry: the index increment of ADIF. Most frequently the
   Chebyshev coefficients are required in adjacent elements of
   ADIF, and IADIF1 must be set to 1. However, if, for example,
   they are to be stored in ADIF(1),ADIF(4),ADIF(7),..., then
   the value of IADIF1 must be 3. See Section 8. Constraint:
   IADIF1 >= 1.

10: LADIF -- INTEGER
    On entry:
    the dimension of the array ADIF as declared in the
    (sub)program from which E02AHF is called.
    Constraint: LADIF>=1+(NP1-1)*IADIF1.

11: IFAIL -- INTEGER
    Input/Output
    On entry: IFAIL must be set to 0, -1 or 1. For users not
    familiar with this parameter (described in the Essential
    Introduction) the recommended value is 0.
    On exit: IFAIL = 0 unless the routine detects an error (see
    Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
    On entry NP1 < 1,
    or     XMAX <= XMIN,
    or     IA1 < 1,
    or     LA<=(NP1-1)*IA1,
    or     IADIF1 < 1,
    or     LADIF<=(NP1-1)*IADIF1.

7. Accuracy

There is always a loss of precision in numerical differentiation,
in this case associated with the multiplication by 2i in the
formula quoted in Section 3.

8. Further Comments

The time taken by the routine is approximately proportional to
n+1.
The increments IA1, IADIF1 are included as parameters to give a degree of flexibility which, for example, allows a polynomial in two variables to be differentiated with respect to either variable without rearranging the coefficients.

9. Example

Suppose a polynomial has been computed in Chebyshev-series form to fit data over the interval [-0.5, 2.5]. The example program evaluates the 1st and 2nd derivatives of this polynomial at 4 equally spaced points over the interval. (For the purposes of this example, XMIN, XMAX and the Chebyshev coefficients are simply supplied in DATA statements. Normally a program would first read in or generate data and compute the fitted polynomial.)

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
not included in the Foundation Library.

1. Purpose

E02AJF determines the coefficients in the Chebyshev-series representation of the indefinite integral of a polynomial given in Chebyshev-series form.

2. Specification

```
SUBROUTINE E02AJF (NP1, XMIN, XMAX, A, IA1, LA, QATM1, 1
                    AINT, IAINT1, LAINT, IFAIL)

INTEGER NP1, IA1, LA, IAINT1, LAINT, IFAIL
DOUBLE PRECISION XMIN, XMAX, A(LA), QATM1, AINT(LAINT)
```

3. Description

This routine forms the polynomial which is the indefinite integral of a given polynomial. Both the original polynomial and its integral are represented in Chebyshev-series form. If supplied with the coefficients \( a_i \), for \( i=0,1,...,n \), of a polynomial \( p(x) \) of degree \( n \), where

\[
1 
\begin{align*}
p(x) &= -a_0 + a_1 T_1(x) + \ldots + a_n T_n(x) , \\
& \quad 2 \quad 1 \\
\end{align*}
\]

the routine returns the coefficients \( a'_i \), for \( i=0,1,...,n+1 \), of the polynomial \( q(x) \) of degree \( n+1 \), where

\[
1 
\begin{align*}
q(x) &= -a'_0 + a'_1 T_1(x) + \ldots + a'_{n+1} T_{n+1}(x) , \\
& \quad 2 \quad 0 \\
\end{align*}
\]

and

\[
q(x) = \int p(x) \, dx.
\]

Here \( T_j(x) \) denotes the Chebyshev polynomial of the first kind of degree \( j \) with argument \( x \). It is assumed that the normalised variable \( x \) in the interval \([-1,+1]\) was obtained from the user's
original variable \( x \) in the interval \([x_{\text{min}}, x_{\text{max}}]\) by the linear
transformation

\[
\begin{align*}
2x - (x_{\text{max}} + x_{\text{min}}) \\
\frac{x}{x_{\text{max}} - x_{\text{min}}} \\
\end{align*}
\]

and that the user requires the integral to be with respect to the
variable \( x \). If the integral with respect to \( x \) is required, set
\( x_{\text{max}} = 1 \) and \( x_{\text{min}} = -1 \).

Values of the integral can subsequently be computed, from the
coefficients obtained, by using E02AKF.

The method employed is that of Chebyshev-series [1] modified for
integrating with respect to \( x \). Initially taking \( a_{n+1} = a_{n+2} = 0 \), the
routine forms successively

\[
\begin{align*}
a^{i-1} - a^{i+1} x_{\text{min}} - x_{\text{max}} \\
\frac{a'}{i 2i 2} \\
\end{align*}
\]

The constant coefficient \( a' \) is chosen so that \( q(x) \) is equal to a
specified value, \( Q_{\text{ATM1}} \), at the lower end-point of the interval on
which it is defined, i.e., \( x_{\text{min}} = -1 \), which corresponds to \( x_{\text{max}} = 1 \).

4. References

HMSO.

5. Parameters

1: NP1 -- INTEGER Input
On entry: \( n+1 \), where \( n \) is the degree of the given
polynomial \( p(x) \). Thus NP1 is the number of coefficients in
this polynomial. Constraint: \( NP1 \geq 1 \).
2: XMIN -- DOUBLE PRECISION Input

3: XMAX -- DOUBLE PRECISION Input
On entry: the lower and upper end-points respectively of
the interval \([x_{\text{min}}, x_{\text{max}}]\). The Chebyshev-series
representation is in terms of the normalised variable \(x\),
where
\[
\frac{2x-(x_{\text{max}}+x_{\text{min}})}{x_{\text{max}}-x_{\text{min}}} = \frac{2x-(x_{\text{max}}+x_{\text{min}})}{x_{\text{max}}-x_{\text{min}}}.
\]
Constraint: \(XMAX > XMIN\).

4: A(LA) -- DOUBLE PRECISION array Input
On entry: the Chebyshev coefficients of the polynomial \(p(x)\).
Specifically, element \(1+i*IA1\) of \(A\) must contain the
coefficient \(a_i\), for \(i=0,1,...,n\). Only these \(n+1\) elements
will be accessed.

Unchanged on exit, but see AINT, below.

5: IA1 -- INTEGER Input
On entry: the index increment of \(A\). Most frequently the
Chebyshev coefficients are stored in adjacent elements of \(A\),
and IA1 must be set to 1. However, if for example, they are
stored in \(A(1),A(4),A(7),...\), then the value of IA1 must be
3. See also Section 8. Constraint: \(IA1 \geq 1\).

6: LA -- INTEGER Input
On entry:
the dimension of the array \(A\) as declared in the (sub)program
from which E02AJF is called.
Constraint: \(LA = 1+(NP1-1)*IA1\).

7: QATM1 -- DOUBLE PRECISION Input
On entry: the value that the integrated polynomial is
required to have at the lower end-point of its interval of
definition, i.e., at \(x=-1\) which corresponds to \(x_{\text{min}}\). Thus,
QATM1 is a constant of integration and will normally be set
to zero by the user.
8: AINT(LAINT) -- DOUBLE PRECISION array
On exit: the Chebyshev coefficients of the integral q(x).
(The integration is with respect to the variable x, and the constant coefficient is chosen so that q(x min)
specifically, element 1+i*IAINT1 of AINT contains the coefficient a’, for i=0,1,...,n+1. A call of the routine
may have the array name AINT the same as A, provided that note is taken of the order in which elements are overwritten when choosing starting elements and increments IA1 and IAINT1: i.e., the coefficients, a ,a ,...,a must be
0 1 i-2
intact after coefficient a’ is stored. In particular it is possible to overwrite the a entirely by having IA1 =
i IAINT1, and the actual array for A and AINT identical.

9: IAINT1 -- INTEGER
On entry: the index increment of AINT. Most frequently the Chebyshev coefficients are required in adjacent elements of AINT, and IAINT1 must be set to 1. However, if, for example, they are to be stored in AINT(1), AINT(4), AINT(7),..., then the value of IAINT1 must be 3. See also Section 8.
Constraint: IAINT1 >= 1.

10: LAINT -- INTEGER
On entry: the dimension of the array AINT as declared in the (sub)program from which E02AJF is called.
Constraint: LAINT >= 1+NP1*IAINT1.

11: IFAIL -- INTEGER
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
On entry NP1 < 1,
or XMAX <= XMIN,
or IA1 < 1,
or LA<=(NP1-1)*IA1,
or IAINT1 < 1,
or LAINT<=NP1*IAINT1.

7. Accuracy

In general there is a gain in precision in numerical integration, in this case associated with the division by 2i in the formula quoted in Section 3.

8. Further Comments

The time taken by the routine is approximately proportional to n+1.

The increments IA1, IAINT1 are included as parameters to give a degree of flexibility which, for example, allows a polynomial in two variables to be integrated with respect to either variable without rearranging the coefficients.

9. Example

Suppose a polynomial has been computed in Chebyshev-series form to fit data over the interval [-0.5,2.5]. The example program evaluates the integral of the polynomial from 0.0 to 2.0. (For the purpose of this example, XMIN, XMAX and the Chebyshev coefficients are simply supplied in DATA statements. Normally a program would read in or generate data and compute the fitted polynomial).

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

Evaluate polynomial in Chebyshev-series representation

— nage.ht —
22.4. NAGE.HT

E02AKF(3NAG)  Foundation Library (12/10/92)  E02AKF(3NAG)

E02 -- Curve and Surface Fitting
E02AKF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E02AKF evaluates a polynomial from its Chebyshev-series representation, allowing an arbitrary index increment for accessing the array of coefficients.

2. Specification

```
SUBROUTINE E02AKF (NP1, XMIN, XMAX, A, IA1, LA, X, RESULT, IFAIL)
  INTEGER NP1, IA1, LA, IFAIL
  DOUBLE PRECISION XMIN, XMAX, A(LA), X, RESULT
```

3. Description

If supplied with the coefficients $a_i$ for $i=0,1,...,n$, of a polynomial $p(x)$ of degree $n$, where

$$
p(x) = -a_0 + a_1 T_1(x) + \cdots + a_n T_n(x),
$$

this routine returns the value of $p(x)$ at a user-specified value of the variable $x$. Here $T_j(x)$ denotes the Chebyshev polynomial of $j$
the first kind of degree $j$ with argument $x$. It is assumed that

the independent variable $x$ in the interval $[-1,+1]$ was obtained from the user’s original variable $x$ in the interval $[x_{\text{min}}, x_{\text{max}}]$ by the linear transformation

$$x = \frac{2x - (x_{\text{max}} + x_{\text{min}})}{x_{\text{max}} - x_{\text{min}}}.$$

The coefficients $a_i$ may be supplied in the array $A$, with any increment between the indices of array elements which contain successive coefficients. This enables the routine to be used in surface fitting and other applications, in which the array might have two or more dimensions.

The method employed is based upon the three-term recurrence relation due to Clenshaw [1], with modifications due to Reinsch and Gentleman (see [4]). For further details of the algorithm and its use see Cox [2] and Cox and Hayes [3].

4. References

5. Parameters

1: NP1 -- INTEGER

Input

On entry: $n+1$, where $n$ is the degree of the given
polynomial \( p(x) \). Constraint: \( NP1 >= 1 \).

2: \( \text{XMIN} \) -- DOUBLE PRECISION  
Input 

3: \( \text{XMAX} \) -- DOUBLE PRECISION  
Input 
On entry: the lower and upper end-points respectively of 
the interval \([x_{\text{min}}, x_{\text{max}}]\). The Chebyshev-series 
representation is in terms of the normalised variable \( x \), 
where 
\[
2x - (x_{\text{max}} + x_{\text{min}})
\]
\[
\frac{x - x_{\text{min}}}{x_{\text{max}} - x_{\text{min}}}
\]
Constraint: \( \text{XMIN} < \text{XMAX} \).

4: \( \text{A(LA)} \) -- DOUBLE PRECISION array  
Input 
On entry: the Chebyshev coefficients of the polynomial \( p(x) \). 
Specifically, element \( i + i \cdot IA1 \) must contain the coefficient 
\( a_i \), for \( i = 0,1,\ldots,n \). Only these \( n+1 \) elements will be 
accessed. 

5: \( \text{IA1} \) -- INTEGER  
Input 
On entry: the index increment of \( \text{A} \). Most frequently, the 
Chebyshev coefficients are stored in adjacent elements of \( \text{A} \), 
and \( \text{IA1} \) must be set to 1. However, if, for example, they are 
stored in \( \text{A}(1), \text{A}(4), \text{A}(7), \ldots \), then the value of \( \text{IA1} \) must be 
3. Constraint: \( \text{IA1} >= 1 \).

6: \( \text{LA} \) -- INTEGER  
Input 
On entry: the dimension of the array \( \text{A} \) as declared in the (sub)program 
from which \( \text{E02AKF} \) is called. 
Constraint: \( \text{LA} >= (NP1-1) \cdot \text{IA1}+1 \).

7: \( \text{X} \) -- DOUBLE PRECISION  
Input 
On entry: the argument \( x \) at which the polynomial is to be 
evaluated. Constraint: \( \text{XMIN} <= X <= \text{XMAX} \).

8: \( \text{RESULT} \) -- DOUBLE PRECISION  
Output 
On exit: the value of the polynomial \( p(x) \).

9: \( \text{EIFAIL} \) -- INTEGER  
Input/Output 
On entry: \( \text{EIFAIL} \) must be set to 0, -1 or 1. For users not
familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
  On entry NP1 < 1,
  or IA1 < 1,
  or LA<=(NP1-1)*IA1,
  or XMIN >= XMAX.

IFAIL= 2
  X does not satisfy the restriction XMIN <= X <= XMAX.

7. Accuracy

The rounding errors are such that the computed value of the polynomial is exact for a slightly perturbed set of coefficients $a + (\delta)a$. The ratio of the sum of the absolute values of the $a$ to the sum of the absolute values of the $a$ is less than a small multiple of $(n+1)\times$ machine precision.

8. Further Comments

The time taken by the routine is approximately proportional to $n+1$.

9. Example

Suppose a polynomial has been computed in Chebyshev-series form to fit data over the interval $[-0.5,2.5]$. The example program evaluates the polynomial at 4 equally spaced points over the interval. (For the purposes of this example, XMIN, XMAX and the Chebyshev coefficients are supplied in DATA statements. Normally a program would first read in or generate data and compute the fitted polynomial.)

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
Weighted least-squares approx to data points

E02BAF (3NAG) Foundation Library (12/10/92) E02BAF (3NAG)

E02 -- Curve and Surface Fitting
E02BAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E02BAF computes a weighted least-squares approximation to an arbitrary set of data points by a cubic spline with knots prescribed by the user. Cubic spline interpolation can also be carried out.

2. Specification

```
SUBROUTINE E02BAF (M, NCAP7, X, Y, W, LAMDA, WORK1, WORK2, C, SS, IFAIL)
INTEGER M, NCAP7, IFAIL
DOUBLE PRECISION X(M), Y(M), W(M), LAMDA(NCAP7), WORK1(M), WORK2(4*NCAP7), C(NCAP7), SS
```

3. Description

This routine determines a least-squares cubic spline
approximation $s(x)$ to the set of data points $(x, y)$ with weights $w$, for $r=1, 2, \ldots, m$. The value of $\text{NCAP7} = n+7$, where $n$ is the number of intervals of the spline (one greater than the number of interior knots), and the values of the knots $(\lambda), (\lambda), \ldots, (\lambda)$, interior to the data interval, are prescribed by the user.

$s(x)$ has the property that it minimizes $(\theta)$, the sum of squares of the weighted residuals $(\epsilon)$, for $r=1, 2, \ldots, m$, where

$$
(\epsilon) = w (y - s(x)).
$$

The routine produces this minimizing value of $(\theta)$ and the coefficients $c_1, c_2, \ldots, c_q$, where $q=n+3$, in the B-spline representation

$$
q
--
\begin{equation}
\begin{aligned}
s(x) &= \sum_{i=1}^{q} c_i N_i(x) \\
\end{aligned}
\end{equation}
$$

Here $N_i(x)$ denotes the normalised B-spline of degree 3 defined upon the knots $(\lambda), (\lambda), \ldots, (\lambda)$. In order to define the full set of B-splines required, eight additional knots $(\lambda), (\lambda), (\lambda), (\lambda)$ and $(\lambda), (\lambda), (\lambda), (\lambda)$ are inserted automatically by the routine. The first four of these are set equal to the smallest $x$ and the last four to the largest $x$. The representation of $s(x)$ in terms of B-splines is the most compact form possible in that only $n+3$ coefficients, in addition
to the \(n+7\) knots, fully define \(s(x)\).

The method employed involves forming and then computing the least-squares solution of a set of \(m\) linear equations in the

coefficients \(c_i (i=1, 2, \ldots, n+3)\). The equations are formed using a recurrence relation for B-splines that is unconditionally stable (Cox [1], de Boor [5]), even for multiple (coincident) knots. The least-squares solution is also obtained in a stable manner by using orthogonal transformations, viz. a variant of Givens rotations (Gentleman [6] and [7]). This requires only one equation to be stored at a time. Full advantage is taken of the structure of the equations, there being at most four non-zero values of \(N(x)\) for any value of \(x\) and hence at most four coefficients in each equation.

For further details of the algorithm and its use see Cox [2], [3] and [4].

Subsequent evaluation of \(s(x)\) from its B-spline representation may be carried out using E02BBF. If derivatives of \(s(x)\) are also required, E02BCF may be used. E02BDF can be used to compute the definite integral of \(s(x)\).

12 329--336.

5. Parameters

1: M -- INTEGER  
On entry: the number m of data points. Constraint: M >= 
MDIST >= 4, where MDIST is the number of distinct x values 
in the data.

2: NCAP7 -- INTEGER  
On entry: n+7, where n is the number of intervals of the 
spline (which is one greater than the number of interior 
knots, i.e., the knots strictly within the range x to x ) 
1 m
over which the spline is defined. Constraint: 8 <= NCAP7 <= 
MDIST + 4, where MDIST is the number of distinct x values in 
the data.

3: X(M) -- DOUBLE PRECISION array  
On entry: the values x of the independent variable 
r 
(abscissa), for r=1,2,...,m. Constraint: x <=x <=...<=x . 
1 2 m

4: Y(M) -- DOUBLE PRECISION array  
On entry: the values y of the dependent variable 
r 
(ordinate), for r=1,2,...,m.

5: W(M) -- DOUBLE PRECISION array  
On entry: the values w of the weights, for r=1,2,...,m.  
r
For advice on the choice of weights, see the Chapter 
Introduction. Constraint: W(r) > 0, for r=1,2,...,m.

6: LAMDA(NCAP7) -- DOUBLE PRECISION array  
On entry: LAMDA(i) must be set to the (i-4)th (interior) 
knot, (lambda), for i=5,6,...,n+3. Constraint: X(1) < LAMDA 

22.4. NAGE.HT

(5) \leq \Lambda(6) \leq \ldots \leq \Lambda(N\text{CAP}7-4) < X(M). On exit: the input values are unchanged, and \Lambda(i), for \text{i} = 1, 2, 3, 4, N\text{CAP}7-3, N\text{CAP}7-2, N\text{CAP}7-1, N\text{CAP}7 contains the additional (exterior) knots introduced by the routine. For advice on the choice of knots, see Section 3.3 of the Chapter Introduction.

7: WORK1(M) -- DOUBLE PRECISION array Workspace

8: WORK2(4*N\text{CAP}7) -- DOUBLE PRECISION array Workspace

9: C(N\text{CAP}7) -- DOUBLE PRECISION array Output
   On exit: the coefficient c \text{ of the B-spline N(x), for } i = 1, 2, \ldots, n+3. The remaining elements of the array are not used.

10: SS -- DOUBLE PRECISION Output
   On exit: the residual sum of squares, (\theta).

11: IFAIL -- INTEGER Input/Output
   On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
   On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
The knots fail to satisfy the condition
\text{X(1) < \Lambda(5) \leq \Lambda(6) \leq \ldots \leq \Lambda(N\text{CAP}7-4) < X(M). Thus the knots are not in correct order or are not interior to the data interval.}

IFAIL= 2
The weights are not all strictly positive.

IFAIL= 3
The values of X(r), for r = 1,2,\ldots,M are not in non-decreasing order.

IFAIL= 4
N\text{CAP}7 < 8 (so the number of interior knots is negative) or
CHAPTER 22. NAG LIBRARY ROUTINES

NCAP7 > MDIST + 4, where MDIST is the number of distinct x values in the data (so there cannot be a unique solution).

IFAIL= 5
The conditions specified by Schoenberg and Whitney [8] fail to hold for at least one subset of the distinct data abscissae. That is, there is no subset of NCAP7-4 strictly increasing values, X(R(1)), X(R(2)), ..., X(R(NCAP7-4)), among the abscissae such that

\[ X(R(1)) < \lambda(1) < X(R(5)), \]

\[ X(R(2)) < \lambda(2) < X(R(6)), \]

\[ \ldots \]

\[ X(R(NCAP7-8)) < \lambda(NCAP7-8) < X(R(NCAP7-4)). \]

This means that there is no unique solution: there are regions containing too many knots compared with the number of data points.

7. Accuracy
The rounding errors committed are such that the computed coefficients are exact for a slightly perturbed set of ordinates \( y + \delta y \). The ratio of the root-mean-square value for the \( r \) \( r \)
\( \delta y \) to the root-mean-square value of the \( y \) can be expected to be less than a small multiple of \((\kappa)\cdot m \cdot \text{machine precision}\), where \((\kappa)\) is a condition number for the problem. Values of \((\kappa)\) for 20-30 practical data sets all proved to lie between 4.5 and 7.8 (see Cox [3]). (Note that for these data sets, replacing the coincident end knots at the end-points \( x_1 \) and \( x_m \) used in the routine by various choices of non-coincident exterior knots gave values of \((\kappa)\) between 16 and 180. Again see Cox [3] for further details.) In general we would not expect \((\kappa)\) to be large unless the choice of knots results in near-violation of the Schoenberg-Whitney conditions.

A cubic spline which adequately fits the data and is free from spurious oscillations is more likely to be obtained if the knots are chosen to be grouped more closely in regions where the function (underlying the data) or its derivatives change more rapidly than elsewhere.

8. Further Comments
The time taken by the routine is approximately \( C \times (2m+n+7) \) seconds, where \( C \) is a machine-dependent constant.

Multiple knots are permitted as long as their multiplicity does not exceed 4, i.e., the complete set of knots must satisfy

\[ (\lambda_i) < (\lambda_{i+4}) \quad \text{for } i=1,2,\ldots,n+3, \quad \text{(cf. Section 6)}. \]

At a knot of multiplicity one (the usual case), \( s(x) \) and its first two derivatives are continuous. At a knot of multiplicity two, \( s(x) \) and its first derivative are continuous. At a knot of multiplicity three, \( s(x) \) is continuous, and at a knot of multiplicity four, \( s(x) \) is generally discontinuous.

The routine can be used efficiently for cubic spline interpolation, i.e., if \( m=n+3 \). The abscissae must then of course satisfy \( x_1 < x_2 < \ldots < x_m \). Recommended values for the knots in this case are \( \lambda_i = x_i \), for \( i=5,6,\ldots,n+3 \).

9. Example

Determine a weighted least-squares cubic spline approximation with five intervals (four interior knots) to a set of 14 given data points. Tabulate the data and the corresponding values of the approximating spline, together with the residual errors, and also the values of the approximating spline at points half-way between each pair of adjacent data points.

The example program is written in a general form that will enable a cubic spline approximation with \( n \) intervals (\( n-1 \) interior knots) to be obtained to \( m \) data points, with arbitrary positive weights, and the approximation to be tabulated. Note that E02BBF is used to evaluate the approximating spline. The program is self-starting in that any number of data sets can be supplied.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
Evaluates a cubic spline from its B-spline representation

1. Purpose

E02BBF evaluates a cubic spline from its B-spline representation.

2. Specification

```fortran
SUBROUTINE E02BBF (NCAP7, LAMDA, C, X, S, IFAIL)
INTEGER NCAP7, IFAIL
DOUBLE PRECISION LAMDA(NCAP7), C(NCAP7), X, S
```

3. Description

This routine evaluates the cubic spline $s(x)$ at a prescribed argument $x$ from its augmented knot set $(\lambda_i)$, for $i = 1,2,\ldots,n+7$, (see E02BAF) and from the coefficients $c_i$, for $i = 1,2,\ldots,q$ in its B-spline representation.
Here \( q = n + 3 \), where \( n \) is the number of intervals of the spline, and \( N(x) \) denotes the normalised B-spline of degree 3 defined upon the knots \( \lambda_i, \lambda_{i+1}, \ldots, \lambda_{i+4} \). The prescribed argument \( x \) must satisfy \( \lambda_i \leq x \leq \lambda_{i+4} \).

It is assumed that \( \lambda_j \geq \lambda_{j-1} \), for \( j = 2, 3, \ldots, n + 7 \), and \( \lambda_j > \lambda_{n+4} \).

The method employed is that of evaluation by taking convex combinations due to de Boor [4]. For further details of the algorithm and its use see Cox [1] and [3].

It is expected that a common use of E02BBF will be the evaluation of the cubic spline approximations produced by E02BAF. A generalization of E02BBF which also forms the derivative of \( s(x) \) is E02BCF. E02BCF takes about 50% longer than E02BBF.

### 4. References

### 5. Parameters
1: NCAP7 -- INTEGER Input

On entry: n+7, where n is the number of intervals (one greater than the number of interior knots, i.e., the knots strictly within the range (lambda) to (lambda) ) over
n+4
which the spline is defined. Constraint: NCAP7 >= 8.

2: LAMDA(NCAP7) -- DOUBLE PRECISION array Input

On entry: LAMDA(j) must be set to the value of the jth member of the complete set of knots, (lambda) for
j
j=1,2,...,n+7. Constraint: the LAMDA(j) must be in non-decreasing order with LAMDA(NCAP7-3) > LAMDA(4).

3: C(NCAP7) -- DOUBLE PRECISION array Input

On entry: the coefficient c of the B-spline N(x), for
i
i=1,2,...,n+3. The remaining elements of the array are not used.

4: X -- DOUBLE PRECISION Input

On entry: the argument x at which the cubic spline is to be evaluated. Constraint: LAMDA(4) <= X <= LAMDA(NCAP7-3).

5: S -- DOUBLE PRECISION Output

On exit: the value of the spline, s(x).

6: IFAIL -- INTEGER Input/Output

On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
The argument X does not satisfy LAMDA(4) <= X <= LAMDA(NCAP7-3).
In this case the value of S is set arbitrarily to zero.

IFAIL= 2
NCAP7 < 8, i.e., the number of interior knots is negative.

7. Accuracy

The computed value of \( s(x) \) has negligible error in most practical situations. Specifically, this value has an absolute error bounded in modulus by \( 18c \cdot \text{machine precision} \), where \( c \) is the largest in modulus of \( c_j, c_{j+1}, c_{j+2}, c_{j+3} \) and \( j \) is an integer such that \( \lambda_j \leq x \leq \lambda_{j+3} \). If \( c_j, c_{j+1}, c_{j+2} \) and \( c_{j+3} \) are all of the same sign, then the computed value of \( s(x) \) has a relative error not exceeding \( 20 \cdot \text{machine precision} \) in modulus. For further details see Cox [2].

8. Further Comments

The time taken by the routine is approximately \( C \cdot (1 + 0.1 \log(n+7)) \) seconds, where \( C \) is a machine-dependent constant.

Note: the routine does not test all the conditions on the knots given in the description of LAMDA in Section 5, since to do this would result in a computation time approximately linear in \( n+7 \) instead of \( \log(n+7) \). All the conditions are tested in E02BAF, however.

9. Example

Evaluate at 9 equally-spaced points in the interval \( 1.0 \leq x \leq 9.0 \) the cubic spline with (augmented) knots \( 1.0, 1.0, 1.0, 1.0, 3.0, 6.0, 8.0, 9.0, 9.0, 9.0, 9.0 \) and normalised cubic B-spline coefficients \( 1.0, 2.0, 4.0, 7.0, 6.0, 4.0, 3.0 \).

The example program is written in a general form that will enable a cubic spline with \( n \) intervals, in its normalised cubic B-spline form, to be evaluated at \( m \) equally-spaced points in the interval \( \text{LAMDA}(4) \leq x \leq \text{LAMDA}(n+4) \). The program is self-starting in that any number of data sets may be supplied.
Evaluate cubic spline and 3 derivatives from B-spline

E02BCF(3NAG) Foundation Library (12/10/92) E02BCF(3NAG)

E02 -- Curve and Surface Fitting

E02BCF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E02BCF evaluates a cubic spline and its first three derivatives from its B-spline representation.

2. Specification

```fortran
SUBROUTINE E02BCF (NCAP7, LAMDA, C, X, LEFT, S, IFAIL)
INTEGER NCAP7, LEFT, IFAIL
DOUBLE PRECISION LAMDA(NCAP7), C(NCAP7), X, S(4)
```

3. Description

This routine evaluates the cubic spline \( s(x) \) and its first three derivatives at a prescribed argument \( x \). It is assumed that \( s(x) \)
is represented in terms of its B-spline coefficients $c_i$ for $i=1,2,\ldots,n+3$ and (augmented) ordered knot set $(\lambda_i)$, for $i=1,2,\ldots,n+7$, (see E02BAF), i.e.,

$$s(x) = \sum_{i=1}^{q} c_i N_i(x)$$

Here $q=n+3$, $n$ is the number of intervals of the spline and $N_i(x)$ denotes the normalised B-spline of degree 3 (order 4) defined upon the knots $\lambda_i, \lambda_{i+1}, \ldots, \lambda_{i+4}$. The prescribed argument $x$ must satisfy

$$\lambda_i \leq x \leq \lambda_{n+4}$$

At a simple knot $\lambda_i$ (i.e., one satisfying $\lambda_{i-1} < \lambda_i < \lambda_{i+1}$), the third derivative of the spline is in general discontinuous. At a multiple knot (i.e., two or more knots with the same value), lower derivatives, and even the spline itself, may be discontinuous. Specifically, at a point $x=u$ where (exactly) $r$ knots coincide (such a point is termed a knot of multiplicity $r$), the values of the derivatives of order $4-j$, for $j=1,2,\ldots,r$, are in general discontinuous. (Here $1 \leq r \leq 4$; $r > 4$ is not meaningful.) The user must specify whether the value at such a point is required to be the left- or right-hand derivative.

The method employed is based upon:

(i) carrying out a binary search for the knot interval containing the argument $x$ (see Cox [3]),

(ii) evaluating the non-zero B-splines of orders 1,2,3 and 4 by recurrence (see Cox [2] and [3]).
(iii) computing all derivatives of the B-splines of order 4 by applying a second recurrence to these computed B-spline values (see de Boor [1]),

(iv) multiplying the 4th-order B-spline values and their derivative by the appropriate B-spline coefficients, and summing, to yield the values of s(x) and its derivatives.

E02BCF can be used to compute the values and derivatives of cubic spline fits and interpolants produced by E02BAF.

If only values and not derivatives are required, E02BBF may be used instead of E02BCF, which takes about 50% longer than E02BBF.

4. References

5. Parameters

1: NCAP7 -- INTEGER Input

On entry: n+7, where n is the number of intervals of the spline (which is one greater than the number of interior knots, i.e., the knots strictly within the range (lambda) to (lambda) over which the spline is defined).

Constraint: NCAP7 >= 8.

2: LAMDA(NCAP7) -- DOUBLE PRECISION array Input

On entry: LAMDA(j) must be set to the value of the jth member of the complete set of knots, (lambda), for j = 1,2,...,n+7. Constraint: the LAMDA(j) must be in non-decreasing order with LAMDA(NCAP7-3) > LAMDA(4).

3: C(NCAP7) -- DOUBLE PRECISION array Input
On entry: the coefficient $c$ of the $B$-spline $N_i(x)$, for $i=1,2,\ldots,n+3$. The remaining elements of the array are not used.

4: $X$ -- DOUBLE PRECISION Input
On entry: the argument $x$ at which the cubic spline and its derivatives are to be evaluated. Constraint: $\text{LAMDA}(4) \leq X \leq \text{LAMDA}(\text{NCAP7}-3)$.

5: $\text{LEFT}$ -- INTEGER Input
On entry: specifies whether left- or right-hand values of the spline and its derivatives are to be computed (see Section 3). Left- or right-hand values are formed according to whether $\text{LEFT}$ is equal or not equal to 1. If $x$ does not coincide with a knot, the value of $\text{LEFT}$ is immaterial. If $x = \text{LAMDA}(4)$, right-hand values are computed, and if $x = \text{LAMDA}(\text{NCAP7}-3)$, left-hand values are formed, regardless of the value of $\text{LEFT}$.

6: $S(4)$ -- DOUBLE PRECISION array Output
On exit: $S(j)$ contains the value of the $(j-1)$th derivative of the spline at the argument $x$, for $j = 1,2,3,4$. Note that $S(1)$ contains the value of the spline.

7: $\text{IFAIL}$ -- INTEGER Input/Output
On entry: $\text{IFAIL}$ must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: $\text{IFAIL} = 0$ unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

$\text{IFAIL} = 1$
NCAP7 < 8, i.e., the number of intervals is not positive.

$\text{IFAIL} = 2$
Either $\text{LAMDA}(4) \geq \text{LAMDA}(\text{NCAP7}-3)$, i.e., the range over which $s(x)$ is defined is null or negative in length, or $X$ is an invalid argument, i.e., $X < \text{LAMDA}(4)$ or $X > \text{LAMDA}(\text{NCAP7}-3)$.

7. Accuracy

The computed value of $s(x)$ has negligible error in most practical
situations. Specifically, this value has an absolute error bounded in modulus by $18c \cdot 18\star c \cdot \text{machine precision}$, where $c$ is the largest in modulus of $c$, $c$, $c$, and $c$, and $j$ is an integer such that $(\lambda_j) \leq x \leq (\lambda_{j+3})$. If $c$, $c$, $c$, and $c$ are all of the same sign, then the computed value of $s(x)$ has relative error bounded by $18\star \text{machine precision}$. For full details see Cox [3].

No complete error analysis is available for the computation of the derivatives of $s(x)$. However, for most practical purposes the absolute errors in the computed derivatives should be small.

8. Further Comments

The time taken by this routine is approximately linear in $\log(n+7)$.

Note: the routine does not test all the conditions on the knots given in the description of LAMDA in Section 5, since to do this would result in a computation time approximately linear in $n+7$ instead of $\log(n+7)$. All the conditions are tested in E02BAF, however.

9. Example

Compute, at the 7 arguments $x = 0, 1, 2, 3, 4, 5, 6$, the left- and right-hand values and first 3 derivatives of the cubic spline defined over the interval $0 \leq x \leq 6$ having the 6 interior knots $x = 1, 3, 3, 3, 4, 4$, the 8 additional knots $0, 0, 0, 0, 6, 6, 6, 6$, and the 10 B-spline coefficients $10, 12, 13, 15, 22, 26, 24, 18, 14, 12$.

The input data items (using the notation of Section 5) comprise the following values in the order indicated:

\[
\begin{align*}
n & \quad m \\
LAMDA(j), & \quad \text{for } j = 1, 2, \ldots, \text{NCAP7}
\end{align*}
\]
The example program is written in a general form that will enable the values and derivatives of a cubic spline having an arbitrary number of knots to be evaluated at a set of arbitrary points. Any number of data sets may be supplied. The only changes required to the program relate to the dimensions of the arrays LAMDA and C.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

---

**Definite integral of cubic spline from B-spline**

---

E02BDF computes the definite integral of a cubic spline from its B-spline representation.
2. Specification

SUBROUTINE E02BDF (NCAP7, LAMDA, C, DEFINT, IFAIL)
INTEGER NCAP7, IFAIL
DOUBLE PRECISION LAMDA(NCAP7), C(NCAP7), DEFINT

3. Description

This routine computes the definite integral of the cubic spline
\[ s(x) \] between the limits \( x=a \) and \( x=b \), where \( a \) and \( b \) are
respectively the lower and upper limits of the range over which
\( s(x) \) is defined. It is assumed that \( s(x) \) is represented in terms
of its B-spline coefficients \( c_i \), for \( i=1,2,\ldots,n+3 \) and

\[ (\text{augmented) ordered knot set } (\lambda_i), \text{ for } i=1,2,\ldots,n+7, \text{ with } \]
\[ (\lambda_i) = a, \text{ for } i = 1,2,3,4 \text{ and } (\lambda_i) = b, \text{ for } \]
\[ i = n+4,n+5,n+6,n+7, \text{ (see E02BAF), i.e., } \]

\[ \sum_{i=1}^{q} c_i N_i(x) = \int_a^b s(x) \, dx \]

Here \( q=n+3 \), \( n \) is the number of intervals of the spline and \( N_i(x) \) denotes the normalised B-spline of degree 3 (order 4) defined
upon the knots \( (\lambda_i),(\lambda_{i+1}),\ldots,(\lambda_{i+4}) \).

The method employed uses the formula given in Section 3 of Cox [1].

E02BDF can be used to determine the definite integrals of cubic
spline fits and interpolants produced by E02BAF.

4. References

5. Parameters

1: NCAP7 -- INTEGER  
   On entry: n+7, where n is the number of intervals of the 
   spline (which is one greater than the number of interior 
   knots, i.e., the knots strictly within the range a to b) 
   over which the spline is defined. Constraint: NCAP7 >= 8.

2: LAMDA(NCAP7) -- DOUBLE PRECISION array  
   On entry: LAMDA(j) must be set to the value of the jth 
   member of the complete set of knots, (lambda) for 
   j

   j=1,2,...,n+7. Constraint: the LAMDA(j) must be in non-
   decreasing order with LAMDA(NCAP7-3) > LAMDA(4) and satisfy
   LAMDA(1)=LAMDA(2)=LAMDA(3)=LAMDA(4)

   and

   LAMDA(NCAP7-3)=LAMDA(NCAP7-2)=LAMDA(NCAP7-1)=LAMDA(NCAP7).

3: C(NCAP7) -- DOUBLE PRECISION array  
   On entry: the coefficient c of the B-spline N (x), for 
   i

   i=1,2,...,n+3. The remaining elements of the array are not 
   used.

4: DEFINT -- DOUBLE PRECISION  
   On exit: the value of the definite integral of s(x) between 
   the limits x=a and x=b, where a=(lambda) and b=(lambda) .

   4 n+4

5: IFAIL -- INTEGER  
   On entry: IFAIL must be set to 0, -1 or 1. For users not 
   familiar with this parameter (described in the Essential 
   Introduction) the recommended value is 0.

   On exit: IFAIL = 0 unless the routine detects an error (see 
   Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:
If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1
NCAP7 < 8, i.e., the number of intervals is not positive.

IFAIL= 2
At least one of the following restrictions on the knots is violated:
\[ \text{LAMDA}(\text{NCAP7}-3) > \text{LAMDA}(4), \]
\[ \text{LAMDA}(j) >= \text{LAMDA}(j-1), \]
for \( j = 2,3,\ldots,\text{NCAP7} \), with equality in the cases \( j=2,3,4,\text{NCAP7}-2,\text{NCAP7}-1, \) and \( \text{NCAP7}. \)

7. Accuracy
The rounding errors are such that the computed value of the integral is exact for a slightly perturbed set of B-spline coefficients \( c \) differing in a relative sense from those supplied by no more than \( 2.2*(n+3)\times \text{machine precision}. \)

8. Further Comments
The time taken by the routine is approximately proportional to \( n+7. \)

9. Example
Determine the definite integral over the interval \( 0 \leq x \leq 6 \) of a cubic spline having 6 interior knots at the positions (lambda)=1, 3, 3, 3, 4, 4, the 8 additional knots 0, 0, 0, 0, 6, 6, 6, 6, and the 10 B-spline coefficients 10, 12, 13, 15, 22, 26, 24, 18, 14, 12.

The input data items (using the notation of Section 5) comprise the following values in the order indicated:

\[ n \]
\[ \text{LAMDA}(j) \text{ for } j = 1,2,\ldots,\text{NCAP7} \]
\[ , \]
\[ C(j) \text{ for } j = 1,2,\ldots,\text{NCAP7}-3 \]
The example program is written in a general form that will enable the definite integral of a cubic spline having an arbitrary number of knots to be computed. Any number of data sets may be supplied. The only changes required to the program relate to the dimensions of the arrays LAMDA and C.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

Cubic spline approximation to an arbitrary set points

1. Purpose

E02BEF computes a cubic spline approximation to an arbitrary set of data points. The knots of the spline are located automatically, but a single parameter must be specified to control the trade-off between closeness of fit and smoothness of fit.

2. Specification
3. Description

This routine determines a smooth cubic spline approximation \( s(x) \) to the set of data points \( (x_r, y_r) \), with weights \( w_r \), for \( r = 1, 2, \ldots, m \).

The spline is given in the B-spline representation

\[
 s(x) = \sum_{i=1}^{n-4} c_i N_i(x) \quad (1)
\]

where \( N_i(x) \) denotes the normalised cubic B-spline defined upon the knots \( \lambda_i, \lambda_{i+1}, \ldots, \lambda_i \).

The total number \( n \) of these knots and their values \( \lambda_1, \ldots, \lambda_n \) are chosen automatically by the routine.

The knots \( \lambda_1, \ldots, \lambda_{n-4} \) are the interior knots; they divide the approximation interval \( [x_1, x_m] \) into \( n-7 \) sub-intervals.

The coefficients \( c_1, c_2, \ldots, c_{n-4} \) are then determined as the solution of the following constrained minimization problem:

\[
 \text{minimize} \quad \sum_{i=5}^{n-4} (\delta_i) \quad (2)
\]

subject to the constraint

\[
 m
\]
\[
\frac{\Delta}{r} \geq \frac{\epsilon_2}{r} \leq \frac{\sum_i}{S}
\]

(3)

where: \( \Delta \) stands for the discontinuity jump in the third order derivative of \( s(x) \) at the interior knot \( \lambda_i \),

\[\epsilon = \text{weighted residual} \quad w(y - s(x)) \quad r \quad r \quad r \]

and \( S \) is a non-negative number to be specified by the user.

The quantity \( \eta \) can be seen as a measure of the (lack of) smoothness of \( s(x) \), while closeness of fit is measured through \( \theta \). By means of the parameter \( S \), 'the smoothing factor', the user will then control the balance between these two (usually conflicting) properties. If \( S \) is too large, the spline will be too smooth and signal will be lost (underfit); if \( S \) is too small, the spline will pick up too much noise (overfit). In the extreme cases the routine will return an interpolating spline \( (\theta = 0) \) if \( S \) is set to zero, and the weighted least-squares cubic polynomial \( (\eta = 0) \) if \( S \) is set very large. Experimenting with \( S \) values between these two extremes should result in a good compromise. (See Section 8.2 for advice on choice of \( S \).)

The method employed is outlined in Section 8.3 and fully described in Dierckx [1], [2] and [3]. It involves an adaptive strategy for locating the knots of the cubic spline (depending on the function underlying the data and on the value of \( S \)), and an iterative method for solving the constrained minimization problem once the knots have been determined.

Values of the computed spline, or of its derivatives or definite integral, can subsequently be computed by calling E02BBF, E02BCF or E02BDF, as described in Section 8.4.

4. References

5. Parameters

1: START -- CHARACTER*1  Input
On entry: START must be set to 'C' or 'W'.

If START = 'C' (Cold start), the routine will build up the knot set starting with no interior knots. No values need be assigned to the parameters N, LAMDA, WRK or IWRK.

If START = 'W' (Warm start), the routine will restart the knot-placing strategy using the knots found in a previous call of the routine. In this case, the parameters N, LAMDA, WRK, and IWRK must be unchanged from that previous call. This warm start can save much time in searching for a satisfactory value of S. Constraint: START = 'C' or 'W'.

2: M -- INTEGER  Input
On entry: m, the number of data points. Constraint: M >= 4.

3: X(M) -- DOUBLE PRECISION array  Input
On entry: the values x of the independent variable r
(abscissa) x, for r=1,2,...,m. Constraint: x <x <...<x
1 2 m

4: Y(M) -- DOUBLE PRECISION array  Input
On entry: the values y of the dependent variable r
(ordinate) y, for r=1,2,...,m.

5: W(M) -- DOUBLE PRECISION array  Input
On entry: the values w of the weights, for r=1,2,...,m.

For advice on the choice of weights, see the Chapter Introduction, Section 2.1.2. Constraint: W(r) > 0, for r=1,2,...,m.

6: S -- DOUBLE PRECISION  Input
On entry: the smoothing factor, S.

If S=0.0, the routine returns an interpolating spline.

If S is smaller than machine precision, it is assumed equal
to zero.

For advice on the choice of \( S \), see Section 3 and Section 8.2
Constraint: \( S \geq 0.0 \).

7: \textbf{NEST} -- INTEGER
Input
On entry: an over-estimate for the number, \( n \), of knots
required. Constraint: \( \text{NEST} \geq 8 \). In most practical
situations, \( \text{NEST} = M/2 \) is sufficient. \( \text{NEST} \) never needs to be
larger than \( M + 4 \), the number of knots needed for
interpolation (\( S = 0.0 \)).

8: \textbf{N} -- INTEGER
Input/Output
On entry: if the warm start option is used, the value of \( N \)
must be left unchanged from the previous call. On exit: the
total number, \( n \), of knots of the computed spline.

9: \textbf{LAMDA(NEST)} -- DOUBLE PRECISION array
Input/Output
On entry: if the warm start option is used, the values
\( \text{LAMDA}(1), \text{LAMDA}(2), \ldots, \text{LAMDA}(N) \) must be left unchanged from
the previous call. On exit: the knots of the spline i.e.,
the positions of the interior knots \( \text{LAMDA}(5), \text{LAMDA}(6), \ldots \),
\( \text{LAMDA}(N-4) \) as well as the positions of the additional knots
\( \text{LAMDA}(1) = \text{LAMDA}(2) = \text{LAMDA}(3) = \text{LAMDA}(4) = x \) and
\( x \)
\( \text{LAMDA}(N-3) = \text{LAMDA}(N-2) = \text{LAMDA}(N-1) = \text{LAMDA}(N) = x \) needed
\( m \)
for the B-spline representation.

10: \textbf{C(NEST)} -- DOUBLE PRECISION array
Output
On exit: the coefficient \( c \) of the B-spline \( N(x) \) in the
spline approximation \( s(x) \), for \( i = 1, 2, \ldots, n-4 \).

11: \textbf{FP} -- DOUBLE PRECISION
Output
On exit: the sum of the squared weighted residuals, \( \theta \),
of the computed spline approximation. If \( FP = 0.0 \), this is
an interpolating spline. \( FP \) should equal \( S \) within a relative
tolerance of \( 0.001 \) unless \( n=8 \) when the spline has no
interior knots and so is simply a cubic polynomial. For
knots to be inserted, \( S \) must be set to a value below the
value of \( FP \) produced in this case.

12: \textbf{WRK(LWRK)} -- DOUBLE PRECISION array
Workspace
On entry: if the warm start option is used, the values \( \text{WRK}(1), \ldots, \text{WRK}(n) \) must be left unchanged from the previous
call.

13: \textbf{LWRK} -- INTEGER
Input
On entry:
the dimension of the array WRK as declared in the
(sub)program from which E02BEF is called.
Constraint: LWRK>=4*M+16*NEST+41.

14: IWRK(NEST) -- INTEGER array Workspace
On entry: if the warm start option is used, the values IWRK
(1), ..., IWRK(n) must be left unchanged from the previous
call.
This array is used as workspace.

15: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not
familiar with this parameter (described in the Essential
Introduction) the recommended value is 0.
On exit: IFAIL = 0 unless the routine detects an error (see
Section 6).

6. Error Indicators and Warnings
Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
On entry START /= 'C' or 'W',
or M < 4,
or S < 0.0,
or S = 0.0 and NEST < M + 4,
or NEST < 8,
or LWRK<4*M+16*NEST+41.

IFAIL= 2
The weights are not all strictly positive.

IFAIL= 3
The values of X(r), for r=1,2,...,M, are not in strictly
increasing order.

IFAIL= 4
The number of knots required is greater than NEST. Try
increasing NEST and, if necessary, supplying larger arrays
for the parameters LAMDA, C, WRK and IWRK. However, if NEST is already large, say NEST > M/2, then this error exit may indicate that S is too small.

IFAIL = 5
The iterative process used to compute the coefficients of the approximating spline has failed to converge. This error exit may occur if S has been set very small. If the error persists with increased S, consult NAG.

If IFAIL = 4 or 5, a spline approximation is returned, but it fails to satisfy the fitting criterion (see (2) and (3) in Section 3) – perhaps by only a small amount, however.

7. Accuracy
On successful exit, the approximation returned is such that its weighted sum of squared residuals FP is equal to the smoothing factor S, up to a specified relative tolerance of 0.001 – except that if n=8, FP may be significantly less than S: in this case the computed spline is simply a weighted least-squares polynomial approximation of degree 3, i.e., a spline with no interior knots.

8. Further Comments

8.1. Timing
The time taken for a call of E02BEF depends on the complexity of the shape of the data, the value of the smoothing factor S, and the number of data points. If E02BEF is to be called for different values of S, much time can be saved by setting START =

8.2. Choice of S
If the weights have been correctly chosen (see Section 2.1.2 of the Chapter Introduction), the standard deviation of w y would r r be the same for all r, equal to (sigma), say. In this case, choosing the smoothing factor S in the range (sigma) (m+\sqrt{2m}), as suggested by Reinsch [4], is likely to give a good start in the search for a satisfactory value. Otherwise, experimenting with different values of S will be required from the start, taking account of the remarks in Section 3.

In that case, in view of computation time and memory requirements, it is recommended to start with a very large value for S and so determine the least-squares cubic polynomial; the value returned for FP, call it FP , gives an upper bound for S.
Then progressively decrease the value of \( S \) to obtain closer fits — say by a factor of 10 in the beginning, i.e., \( S = FP /10, S = FP /100, \) and so on, and more carefully as the approximation shows more details.

The number of knots of the spline returned, and their location, generally depend on the value of \( S \) and on the behaviour of the function underlying the data. However, if \( E02BEF \) is called with \( \text{START} = 'W' \), the knots returned may also depend on the smoothing factors of the previous calls. Therefore if, after a number of trials with different values of \( S \) and \( \text{START} = 'W' \), a fit can finally be accepted as satisfactory, it may be worthwhile to call \( E02BEF \) once more with the selected value for \( S \) but now using \( \text{START} = 'C' \). Often, \( E02BEF \) then returns an approximation with the same quality of fit but with fewer knots, which is therefore better if data reduction is also important.

8.3. Outline of Method Used

If \( S=0 \), the requisite number of knots is known in advance, i.e., \( n = m + 4 \); the interior knots are located immediately as \( \lambda_i = x_{i-2} \), for \( i=5,6,...,n-4 \). The corresponding least-squares spline (see \( E02BAF \)) is then an interpolating spline and therefore a solution of the problem.

If \( S>0 \), a suitable knot set is built up in stages (starting with no interior knots in the case of a cold start but with the knot set found in a previous call if a warm start is chosen). At each stage, a spline is fitted to the data by least-squares (see \( E02BAF \)) and \( (\theta) \), the weighted sum of squares of residuals, is computed. If \( (\theta)>S \), new knots are added to the knot set to reduce \( (\theta) \) at the next stage. The new knots are located in intervals where the fit is particularly poor, their number depending on the value of \( S \) and on the progress made so far in reducing \( (\theta) \). Sooner or later, we find that \( (\theta)\leq S \) and at that point the knot set is accepted. The routine then goes on to compute the (unique) spline which has this knot set and which satisfies the full fitting criterion specified by (2) and (3). The theoretical solution has \( (\theta)=S \). The routine computes the spline by an iterative scheme which is ended when \( (\theta)=S \) within a relative tolerance of 0.001. The main part of each iteration consists of a linear least-squares computation of special form, done in a similarly stable and efficient manner as in \( E02BAF \).

An exception occurs when the routine finds at the start that, even with no interior knots \((n=8)\), the least-squares spline
already has its weighted sum of squares of residuals \( \leq S \). In this case, since this spline (which is simply a cubic polynomial) also has an optimal value for the smoothness measure (\( \eta \)), namely zero, it is returned at once as the (trivial) solution. It will usually mean that \( S \) has been chosen too large.

For further details of the algorithm and its use, see Dierckx [3].

8.4. Evaluation of Computed Spline

The value of the computed spline at a given value \( X \) may be obtained in the double precision variable \( S \) by the call:

\[
\text{CALL E02BBF}(N, \text{LAMDA}, C, X, S, \text{IFAIL})
\]

where \( N \), \( \text{LAMDA} \) and \( C \) are the output parameters of E02BEF.

The values of the spline and its first three derivatives at a given value \( X \) may be obtained in the double precision array \( \text{SDIF} \) of dimension at least 4 by the call:

\[
\text{CALL E02BCF}(N, \text{LAMDA}, C, X, \text{LEFT}, \text{SDIF}, \text{IFAIL})
\]

where if \( \text{LEFT} = 1 \), left-hand derivatives are computed and if \( \text{LEFT} \neq 1 \), right-hand derivatives are calculated. The value of \( \text{LEFT} \) is only relevant if \( X \) is an interior knot.

The value of the definite integral of the spline over the interval \( X(1) \) to \( X(M) \) can be obtained in the double precision variable \( \text{SINT} \) by the call:

\[
\text{CALL E02BDF}(N, \text{LAMDA}, C, \text{SINT}, \text{IFAIL})
\]

9. Example

This example program reads in a set of data values, followed by a set of values of \( S \). For each value of \( S \) it calls E02BEF to compute a spline approximation, and prints the values of the knots and the B-spline coefficients \( c_i \).

The program includes code to evaluate the computed splines, by calls to E02BBF, at the points \( x \) and at points mid-way between them. These values are not printed out, however; instead the results are illustrated by plots of the computed splines, together with the data points (indicated by *) and the positions of the knots (indicated by vertical lines): the effect of decreasing \( S \) can be clearly seen. (The plots were obtained by
Minimal, weighted least-squares bicubic spline fit

--- nage.ht ---

Minimal, weighted least-squares bicubic spline fit

--- nage.ht ---
3. Description

This routine determines a bicubic spline fit \( s(x,y) \) to the set of data points \((x_r, y_r, f_r)\) with weights \(w_r\), for \(r=1,2,...,m\). The two sets of internal knots of the spline, \(\{(\lambda)\}\) and \(\{(\mu)\}\), associated with the variables \(x\) and \(y\) respectively, are prescribed by the user. These knots can be thought of as dividing the data region of the \((x,y)\) plane into panels (see diagram in Section 5). A bicubic spline consists of a separate bicubic polynomial in each panel, the polynomials joining together with continuity up to the second derivative across the panel boundaries.

\( s(x,y) \) has the property that \((\Sigma)\), the sum of squares of its weighted residuals \(\rho_r\), for \(r=1,2,...,m\), where

\[
\rho_r = w_r (s(x_r, y_r) - f_r),
\]

is as small as possible for a bicubic spline with the given knot sets. The routine produces this minimized value of \((\Sigma)\) and the coefficients \(c_{ij}\) in the B-spline representation of \(s(x,y)\) - see Section 8. E02DEF and E02DFF are available to compute values of the fitted spline from the coefficients \(c_{ij}\).

The least-squares criterion is not always sufficient to determine the bicubic spline uniquely: there may be a whole family of splines which have the same minimum sum of squares. In these cases, the routine selects from this family the spline for which the sum of squares of the coefficients \(c_{ij}\) is smallest: in other words, the minimal least-squares solution. This choice, although arbitrary, reduces the risk of unwanted fluctuations in the spline fit. The method employed involves forming a system of \(m\) linear equations in the coefficients \(c_{ij}\) and then computing its least-squares solution, which will be the minimal least-squares solution when appropriate. The basis of the method is described in Hayes and Halliday [4]. The matrix of the equation is formed using a recurrence relation for B-splines which is numerically stable (see Cox [1] and de Boor [2] - the former contains the
more elementary derivation but, unlike [2], does not cover the case of coincident knots). The least-squares solution is also obtained in a stable manner by using orthogonal transformations, viz. a variant of Givens rotation (see Gentleman [3]). This requires only one row of the matrix to be stored at a time. Advantage is taken of the stepped-band structure which the matrix possesses when the data points are suitably ordered, there being at most sixteen non-zero elements in any row because of the definition of B-splines. First the matrix is reduced to upper triangular form and then the diagonal elements of this triangle are examined in turn. When an element is encountered whose square, divided by the mean squared weight, is less than a threshold (epsilon), it is replaced by zero and the rest of the elements in its row are reduced to zero by rotations with the remaining rows. The rank of the system is taken to be the number of non-zero diagonal elements in the final triangle, and the non-zero rows of this triangle are used to compute the minimal least-squares solution. If all the diagonal elements are non-zero, the rank is equal to the number of coefficients $c_{ij}$ and the solution obtained is the ordinary least-squares solution, which is unique in this case.

4. References

5. Parameters

1: M -- INTEGER Input
   On entry: the number of data points, $m$. Constraint: $M > 1$.

2: PX -- INTEGER Input
3: PY -- INTEGER Input
   On entry: the total number of knots ($\lambda$) and ($\mu$)
   associated with the variables $x$ and $y$, respectively.
   Constraint: $PX >= 8$ and $PY >= 8$. 

(They are such that PX-8 and PY-8 are the corresponding numbers of interior knots.) The running time and storage required by the routine are both minimized if the axes are labelled so that PY is the smaller of PX and PY.

4: X(M) -- DOUBLE PRECISION array
   Input

5: Y(M) -- DOUBLE PRECISION array
   Input

6: F(M) -- DOUBLE PRECISION array
   Input
   On entry: the co-ordinates of the data point (x ,y ,f ), for
   r r r
   r=1,2,...,m. The order of the data points is immaterial, but
   see the array POINT, below.

7: W(M) -- DOUBLE PRECISION array
   Input
   On entry: the weight w of the rth data point. It is
   r
   important to note the definition of weight implied by the
   equation (1) in Section 3, since it is also common usage to
   define weight as the square of this weight. In this routine,
   each w should be chosen inversely proportional to the
   r
   (absolute) accuracy of the corresponding f , as expressed,
   r
   for example, by the standard deviation or probable error of
   the f . When the f are all of the same accuracy, all the w
   r r
   may be set equal to 1.0.

8: LAMDA(PX) -- DOUBLE PRECISION array
   Input/Output
   On entry: LAMDA(i+4) must contain the ith interior knot
   (lambda) associated with the variable x, for
   i+4
   i=1,2,...,PX-8. The knots must be in non-decreasing order
   and lie strictly within the range covered by the data values
   of x. A knot is a value of x at which the spline is allowed
   to be discontinuous in the third derivative with respect to
   x, though continuous up to the second derivative. This
   degree of continuity can be reduced, if the user requires,
   by the use of coincident knots, provided that no more than
   four knots are chosen to coincide at any point. Two, or
   three, coincident knots allow loss of continuity in,
   respectively, the second and first derivative with respect
   to x at the value of x at which they coincide. Four
   coincident knots split the spline surface into two
   independent parts. For choice of knots see Section 8. On
   exit: the interior knots LAMDA(5) to LAMDA(PX-4) are
   unchanged, and the segments LAMDA(1:4) and LAMDA(PX-3:PX)
contain additional (exterior) knots introduced by the routine in order to define the full set of B-splines required. The four knots in the first segment are all set equal to the lowest data value of \( x \) and the other four additional knots are all set equal to the highest value: there is experimental evidence that coincident end-knots are best for numerical accuracy. The complete array must be left undisturbed if E02DEF or E02DFF is to be used subsequently.

9: \( \text{MU(PY)} \) -- DOUBLE PRECISION array Input
On entry: \( \text{MU}(i+4) \) must contain the \( i \)th interior knot (\( \mu \))

\[ i+4 \]

associated with the variable \( y \), \( i=1,2,...,\text{PY}-8 \). The same remarks apply to \( \text{MU} \) as to \( \text{LAMDA} \) above, with \( Y \) replacing \( X \), and \( y \) replacing \( x \).

10: \( \text{POINT(NPOINT)} \) -- INTEGER array Input
On entry: indexing information usually provided by E02ZAF which enables the data points to be accessed in the order which produces the advantageous matrix structure mentioned in Section 3. This order is such that, if the \((x,y)\) plane is thought of as being divided into rectangular panels by the two sets of knots, all data in a panel occur before data in succeeding panels, where the panels are numbered from bottom to top and then left to right with the usual arrangement of axes, as indicated in the diagram.

Please see figure in printed Reference Manual

A data point lying exactly on one or more panel sides is considered to be in the highest numbered panel adjacent to the point. E02ZAF should be called to obtain the array \( \text{POINT} \), unless it is provided by other means.

11: \( \text{NPOINT} \) -- INTEGER Input
On entry: the dimension of the array \( \text{POINT} \) as declared in the (sub)program from which E02DAF is called.
Constraint: \( \text{NPOINT} \geq M + (\text{PX}-7)*(\text{PY}-7) \).

12: \( \text{DL(NC)} \) -- DOUBLE PRECISION array Output
On exit: \( \text{DL} \) gives the squares of the diagonal elements of the reduced triangular matrix, divided by the mean squared weight. It includes those elements, less than (\( \epsilon \)), which are treated as zero (see Section 3).

13: \( \text{C(NC)} \) -- DOUBLE PRECISION array Output
On exit: \( \text{C} \) gives the coefficients of the fit. \( \text{C}((\text{PY}-4)*(i-1)+j) \) is the coefficient \( c_{ij} \) of Section 3 and Section 8 for \( ij \)
i=1,2,...,PX-4 and j=1,2,...,PY-4. These coefficients are used by E02DEF or E02DFF to calculate values of the fitted function.

14: NC -- INTEGER Input
On entry: the value (PX-4)*(PY-4).

15: WS(NWS) -- DOUBLE PRECISION array Workspace
16: NWS -- INTEGER Input
On entry:
the dimension of the array WS as declared in the (sub)program from which E02DAF is called.
Constraint: NWS>=(2*NC+1)*(3*PY-6)-2.

17: EPS -- DOUBLE PRECISION Input
On entry: a threshold (epsilon) for determining the effective rank of the system of linear equations. The rank is determined as the number of elements of the array DL (see below) which are non-zero. An element of DL is regarded as zero if it is less than (epsilon). Machine precision is a suitable value for (epsilon) in most practical applications which have only 2 or 3 decimals accurate in data. If some coefficients of the fit prove to be very large compared with the data ordinates, this suggests that (epsilon) should be increased so as to decrease the rank. The array DL will give a guide to appropriate values of (epsilon) to achieve this, as well as to the choice of (epsilon) in other cases where some experimentation may be needed to determine a value which leads to a satisfactory fit.

18: SIGMA -- DOUBLE PRECISION Output
On exit: (Sigma), the weighted sum of squares of residuals. This is not computed from the individual residuals but from the right-hand sides of the orthogonally-transformed linear equations. For further details see Hayes and Halliday [4] page 97. The two methods of computation are theoretically equivalent, but the results may differ because of rounding error.

19: RANK -- INTEGER Output
On exit: the rank of the system as determined by the value of the threshold (epsilon). When RANK = NC, the least-squares solution is unique: in other cases the minimal least-squares solution is computed.

20: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL = 1
At least one set of knots is not in non-decreasing order, or an interior knot is outside the range of the data values.

IFAIL = 2
More than four knots coincide at a single point, possibly because all data points have the same value of x (or y) or because an interior knot coincides with an extreme data value.

IFAIL = 3
Array POINT does not indicate the data points in panel order. Call E02ZAF to obtain a correct array.

IFAIL = 4
On entry M <= 1, or PX < 8, or PY < 8, or NC /= (PX-4)*(PY-4), or NWS is too small, or NPOINT is too small.

IFAIL = 5
All the weights w are zero or rank determined as zero.

7. Accuracy

The computation of the B-splines and reduction of the observation matrix to triangular form are both numerically stable.

8. Further Comments

The time taken by this routine is approximately proportional to 2 the number of data points, m, and to (3*(PY-4)+4).
The B-spline representation of the bicubic spline is

\[
s(x,y) = \sum_{i=1}^{PX-4} \sum_{j=1}^{PY-4} c_{ij} M_i(x) N_j(y)
\]

summed over \(i=1,2,\ldots,PX-4\) and over \(j=1,2,\ldots,PY-4\). Here \(M_i(x)\) and \(N_j(y)\) denote normalised cubic B-splines, the former defined on the knots \((\lambda_i, \lambda_i, \ldots, \lambda_i)\) and the latter on \((\mu_j, \mu_j, \ldots, \mu_j)\). For further details, see Hayes and Halliday [4] for bicubic splines and de Boor [2] for normalised B-splines.

The choice of the interior knots, which help to determine the spline’s shape, must largely be a matter of trial and error. It is usually best to start with a small number of knots and, examining the fit at each stage, add a few knots at a time at places where the fit is particularly poor. In intervals of \(x\) or \(y\) where the surface represented by the data changes rapidly, in function value or derivatives, more knots will be needed than elsewhere. In some cases guidance can be obtained by analogy with the case of coincident knots: for example, just as three coincident knots can produce a discontinuity in slope, three close knots can produce rapid change in slope. Of course, such rapid changes in behaviour must be adequately represented by the data points, as indeed must the behaviour of the surface generally, if a satisfactory fit is to be achieved. When there is no rapid change in behaviour, equally-spaced knots will often suffice.

In all cases the fit should be examined graphically before it is accepted as satisfactory.

The fit obtained is not defined outside the rectangle

\[
[\lambda_4, \lambda_{PX-3}, \mu_4, \mu_{PY-3}]
\]

The reason for taking the extreme data values of \(x\) and \(y\) for these four knots is that, as is usual in data fitting, the fit cannot be expected to give satisfactory values outside the data region. If, nevertheless, the user requires values over a larger rectangle, this can be achieved by augmenting the data with two artificial data points \((a,c,0)\) and \((b,d,0)\) with zero weight, where \(a \leq x \leq b\), \(c \leq y \leq d\) defines the enlarged rectangle. In the
case when the data are adequate to make the least-squares solution unique (\text{RANK} = \text{NC}), this enlargement will not affect the fit over the original rectangle, except for possibly enlarged rounding errors, and will simply continue the bicubic polynomials in the panels bordering the rectangle out to the new boundaries: in other cases the fit will be affected. Even using the original rectangle there may be regions within it, particularly at its corners, which lie outside the data region and where, therefore, the fit will be unreliable. For example, if there is no data point in panel 1 of the diagram in Section 5, the least-squares criterion leaves the spline indeterminate in this panel: the minimal spline determined by the subroutine in this case passes through the value zero at the point \((\lambda^1, \mu^1)\).

9. Example

This example program reads a value for \((\epsilon)\), and a set of data points, weights and knot positions. If there are more \(y\) knots than \(x\) knots, it interchanges the \(x\) and \(y\) axes. It calls \text{E02ZAF} to sort the data points into panel order, \text{E02DAF} to fit a bicubic spline to them, and \text{E02DEF} to evaluate the spline at the data points.

Finally it prints:

- the weighted sum of squares of residuals computed from the linear equations;
- the rank determined by \text{E02DAF};
- data points, fitted values and residuals in panel order;
- the weighted sum of squares of the residuals;
- the coefficients of the spline fit.

The program is written to handle any number of data sets.

Note: the data supplied in this example is not typical of a realistic problem: the number of data points would normally be much larger (in which case the array dimensions and the value of \text{NWS} in the program would have to be increased); and the value of \((\epsilon)\) would normally be much smaller on most machines (see Section 5; the relatively large value of \(10^{-6}\) has been chosen in order to illustrate a minimal least-squares solution when \text{RANK} < \text{NC}; in this example \(\text{NC} = 24\)).

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation Library software and should be available on-line.

Bicubic spline approximation to a set of data values

--- nage.ht ---

SUBROUTINE E02DCF (START, MX, X, MY, Y, F, S, NXEST, 1 NYEST, NX, LAMDA, NY, MU, C, FP, WRK, 2 LWRK, IWRK, LIWRK, IFAIL)

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E02DCF computes a bicubic spline approximation to a set of data values, given on a rectangular grid in the x-y plane. The knots of the spline are located automatically, but a single parameter must be specified to control the trade-off between closeness of fit and smoothness of fit.

2. Specification

SUBROUTINE E02DCF (START, MX, X, MY, Y, F, S, NXEST, 1 NYEST, NX, LAMDA, NY, MU, C, FP, WRK, 2 LWRK, IWRK, LIWRK, IFAIL)

INTEGER MX, MY, NXEST, NYEST, NX, NY, LWRK, IWRK, LIWRK, IFAIL

DOUBLE PRECISION X(MX), Y(MY), F(MX*MY), S, LAMDA(NXEST),
3. Description

This routine determines a smooth bicubic spline approximation
\( s(x,y) \) to the set of data points \( (x_q,y_r,f_{qr}) \), for \( q=1,2,\ldots,m \)
and \( r=1,2,\ldots,m \).

The spline is given in the B-spline representation

\[
\begin{align*}
  s(x,y) &= \sum_{i=1}^{n-4} \sum_{j=1}^{n-4} c_{ij} M_i(x) N_j(y), \\
  & \quad (1)
\end{align*}
\]

where \( M_i(x) \) and \( N_j(y) \) denote normalised cubic B-splines, the
\( M_i(x) \) former defined on the knots \( \lambda_1,\ldots,\lambda_n \) and the
\( N_j(y) \) latter on the knots \( \mu_1,\ldots,\mu_n \). For further details, see
Hayes and Halliday [4] for bicubic splines and de Boor [1] for
normalised B-splines.

The total numbers \( n \) and \( n \) of these knots and their values
\( \lambda_1,\ldots,\lambda_n \) and \( \mu_1,\ldots,\mu_n \) are chosen
automatically by the routine. The knots \( \lambda_5,\ldots,\lambda_5 \)
\( \mu_5,\ldots,\mu_5 \) are the interior knots; they
divide the approximation domain \( [x_1,x_m] \times [y_1,y_m] \) into \( (m-7) \times (m-7) \) subpanels \( [\lambda_i,\lambda_{i+1}] \times [\mu_j,\mu_{j+1}] \),
for \( i=4,5,\ldots,n-4 \), \( j=4,5,\ldots,n-4 \). Then, much as in the curve
case (see E02BEF), the coefficients \( c_{ij} \) are determined as the
solution of the following constrained minimization problem:
minimize

\[ (\eta), \quad (2) \]

subject to the constraint

\[
\begin{array}{cccc}
\text{min} & \text{min} \\
\text{f} & \text{f} & 2 \\
\text{x} & \text{y} & \text{x} & \text{y} \\
\text{--} & \text{--} & \text{--} & \text{--} \\
\text{2} & \theta & \geq & \varepsilon \leq S, \\
\text{q} & \text{r} & \text{q} & \text{r} \\
\text{q=1} & \text{r=1}
\end{array}
\]

where \((\eta)\) is a measure of the (lack of) smoothness of \(s(x,y)\). Its value depends on the discontinuity jumps in \(s(x,y)\) across the boundaries of the subpanels. It is zero only when there are no discontinuities and is positive otherwise, increasing with the size of the jumps (see Dierckx [2] for details).

\((\varepsilon)\) denotes the residual \(f - s(x,y)\),

\[
\begin{array}{cccc}
\text{min} & \text{min} \\
\text{f} & \text{f} & \text{q} & \text{r} \\
\text{x} & \text{y} & \text{q} & \text{r} \\
\text{--} & \text{--} & \text{q} & \text{r} \\
\text{q=1} & \text{r=1}
\end{array}
\]

and \(S\) is a non-negative number to be specified by the user.

By means of the parameter \(S\), 'the smoothing factor', the user will then control the balance between smoothness and closeness of fit, as measured by the sum of squares of residuals in (3). If \(S\) is too large, the spline will be too smooth and signal will be lost (underfit); if \(S\) is too small, the spline will pick up too much noise (overfit). In the extreme cases the routine will return an interpolating spline ((\(\theta\)=0) if \(S\) is set to zero, and the least-squares bicubic polynomial ((\(\eta\)=0) if \(S\) is set very large. Experimenting with \(S\)-values between these two extremes should result in a good compromise. (See Section 8.3 for advice on choice of \(S\).)

The method employed is outlined in Section 8.5 and fully described in Dierckx [2] and [3]. It involves an adaptive strategy for locating the knots of the bicubic spline (depending on the function underlying the data and on the value of \(S\)), and an iterative method for solving the constrained minimization problem once the knots have been determined.

Values of the computed spline can subsequently be computed by calling E02DEF or E02DFF as described in Section 8.6.

4. References

5. Parameters

1: START -- CHARACTER*1 Input
   On entry: START must be set to 'C' or 'W'.
   If START = 'C' (Cold start), the routine will build up the knot set starting with no interior knots. No values need be assigned to the parameters NX, NY, LAMDA, MU, WRK or IWRK.
   If START = 'W' (Warm start), the routine will restart the knot-placing strategy using the knots found in a previous call of the routine. In this case, the parameters NX, NY, LAMDA, MU, WRK and IWRK must be unchanged from that previous call. This warm start can save much time in searching for a satisfactory value of S. Constraint: START = 'C' or 'W'.

2: MX -- INTEGER Input
   On entry: m, the number of grid points along the x axis.
   Constraint: MX >= 4.

3: X(MX) -- DOUBLE PRECISION array Input
   On entry: X(q) must be set to x, the x co-ordinate of the qth grid point along the x axis, for q=1,2,...,m.
   Constraint: x <x<...<x.
   1 2 m

4: MY -- INTEGER Input
   On entry: m, the number of grid points along the y axis.
Constraint: MY >= 4.

5: Y(MY) -- DOUBLE PRECISION array Input
On entry: Y(r) must be set to y, the y co-ordinate of the rth grid point along the y axis, for r=1,2,...,m.
Constraint: y <y <...<y.
     1  2   m

6: F(MX*MY) -- DOUBLE PRECISION array Input
On entry: F(m *(q-1)+r) must contain the data value f, y q,r
for q=1,2,...,m and r=1,2,...,m.

7: S -- DOUBLE PRECISION Input
On entry: the smoothing factor, S.
If S=0.0, the routine returns an interpolating spline.
If S is smaller than machine precision, it is assumed equal to zero.
For advice on the choice of S, see Section 3 and Section 8.3
Constraint: S >= 0.0.

8: NXEST -- INTEGER Input

9: NYEST -- INTEGER Input
On entry: an upper bound for the number of knots n and n x y
required in the x- and y-directions respectively.

In most practical situations, NXEST =m/2 and NYEST m/2 is x y sufficient. NXEST and NYEST never need to be larger than m+4 and m+4 respectively, the numbers of knots needed for x y interpolation (S=0.0). See also Section 8.4. Constraint: NXEST >= 8 and NYEST >= 8.

10: NX -- INTEGER Input/Output
On entry: if the warm start option is used, the value of NX must be left unchanged from the previous call. On exit: the total number of knots, n, of the computed spline with x respect to the x variable.
11: LAMDA(NXEST) -- DOUBLE PRECISION array  Input/Output
On entry: if the warm start option is used, the values
LAMDA(1), LAMDA(2),...,LAMDA(NX) must be left unchanged from
the previous call. On exit: LAMDA contains the complete set
of knots (lambda) associated with the x variable, i.e., the
interior knots LAMDA(5), LAMDA(6), ..., LAMDA(NX-4) as well
as the additional knots LAMDA(1) = LAMDA(2) = LAMDA(3) =
LAMDA(4) = X(1) and LAMDA(NX-3) = LAMDA(NX-2) = LAMDA(NX-1) =
LAMDA(NX) = X(MX) needed for the B-spline representation.

12: NY -- INTEGER  Input/Output
On entry: if the warm start option is used, the value of NY
must be left unchanged from the previous call. On exit: the
total number of knots, n, of the computed spline with
respect to the y variable.

13: MU(NYEST) -- DOUBLE PRECISION array  Input/Output
On entry: if the warm start option is used, the values MU
(1), MU(2),...,MU(NY) must be left unchanged from the
previous call. On exit: MU contains the complete set of
knots (mu) associated with the y variable, i.e., the
interior knots MU(5), MU(6),...,MU(NY-4) as well as the
additional knots MU(1) = MU(2) = MU(3) = MU(4) = Y(1) and MU
(NY-3) = MU(NY-2) = MU(NY-1) = MU(NY) = Y(MY) needed for the
B-spline representation.

14: C((NXEST-4)*(NYEST-4)) -- DOUBLE PRECISION array  Output
On exit: the coefficients of the spline approximation. C(\(n-4\times(i-1)+j\)) is the coefficient c_{ij}
defined in Section 3.

15: FP -- DOUBLE PRECISION  Output
On exit: the sum of squared residuals, (theta), of the
computed spline approximation. If FP = 0.0, this is an
interpolating spline. FP should equal S within a relative
tolerance of 0.001 unless NX = NY = 8, when the spline has
no interior knots and so is simply a bicubic polynomial. For
knots to be inserted, S must be set to a value below the
value of FP produced in this case.

16: WRK(LWRK) -- DOUBLE PRECISION array  Workspace
On entry: if the warm start option is used, the values WRK
(1),...,WRK(4) must be left unchanged from the previous
call.

This array is used as workspace.
22.4. NAGE.HT

17: LWRK -- INTEGER  
Input
On entry:
the dimension of the array WRK as declared in the
(sub)program from which E02DCF is called.
Constraint:
\[ LWRK \geq 4\times(MX+MY)+11\times(NXEST+NYEST)+NXEST\times MY \]
\[ + \text{max}(MY,NXEST)+54. \]

18: IWRK(LIWRK) -- INTEGER array  
Workspace
On entry: if the warm start option is used, the values IWRK
(1), ..., IWRK(3) must be left unchanged from the previous
call.

This array is used as workspace.

19: LIWRK -- INTEGER  
Input
On entry:
the dimension of the array IWRK as declared in the
(sub)program from which E02DCF is called.
Constraint: LIWRK \geq 3 + MX + MY + NXEST + NYEST.

20: IFAIL -- INTEGER  
Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not
familiar with this parameter (described in the Essential
Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see
Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL \neq 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
On entry START /= 'C' or 'W',

or MX < 4,

or MY < 4,

or S < 0.0,

or S = 0.0 and NXEST < MX + 4,

or S = 0.0 and NYEST < MY + 4,
or \( \text{NXEST} < 8 \),

or \( \text{NYEST} < 8 \),

or \( \text{LWRK} < 4*(\text{MX}+\text{MY})+11*(\text{NXEST}+\text{NYEST})+\text{NXEST} \times \text{MY}+\max(\text{MY},\text{NXEST})+54 \)

or \( \text{LIWRK} < 3 + \text{MX} + \text{MY} + \text{NXEST} + \text{NYEST} \).

IFAIL = 2
The values of \( X(q) \), for \( q = 1,2,\ldots,\text{MX} \), are not in strictly increasing order.

IFAIL = 3
The values of \( Y(r) \), for \( r = 1,2,\ldots,\text{MY} \), are not in strictly increasing order.

IFAIL = 4
The number of knots required is greater than allowed by \( \text{NXEST} \) and \( \text{NYEST} \). Try increasing \( \text{NXEST} \) and/or \( \text{NYEST} \) and, if necessary, supplying larger arrays for the parameters \( \text{LAMDA}, \text{MU}, \text{C}, \text{WRK} \) and \( \text{IWRK} \). However, if \( \text{NXEST} \) and \( \text{NYEST} \) are already large, say \( \text{NXEST} > \text{MX}/2 \) and \( \text{NYEST} > \text{MY}/2 \), then this error exit may indicate that \( S \) is too small.

IFAIL = 5
The iterative process used to compute the coefficients of the approximating spline has failed to converge. This error exit may occur if \( S \) has been set very small. If the error persists with increased \( S \), consult NAG.

If IFAIL = 4 or 5, a spline approximation is returned, but it fails to satisfy the fitting criterion (see (2) and (3) in Section 3) -- perhaps by only a small amount, however.

7. Accuracy
On successful exit, the approximation returned is such that its sum of squared residuals \( FP \) is equal to the smoothing factor \( S \), up to a specified relative tolerance of 0.001 -- except that if \( n = 8 \) and \( n = 8 \), \( FP \) may be significantly less than \( S \): in this case the computed spline is simply the least-squares bicubic polynomial approximation of degree 3, i.e., a spline with no interior knots.

8. Further Comments

8.1. Timing
The time taken for a call of E02DCF depends on the complexity of the shape of the data, the value of the smoothing factor $S$, and the number of data points. If E02DCF is to be called for different values of $S$, much time can be saved by setting $\text{START} = 'W'$. 

8.2. Weighting of Data Points

E02DCF does not allow individual weighting of the data values. If these were determined to widely differing accuracies, it may be better to use E02DDF. The computation time would be very much longer, however.

8.3. Choice of $S$

If the standard deviation of $f$ is the same for all $q$ and $r$ (the case for which this routine is designed - see Section 8.2.) and known to be equal, at least approximately, to $(\sigma)$, say, then following Reinsch [5] and choosing the smoothing factor $S$ in the range $(\sigma) (m+\sqrt{2m})$, where $m=m_x m_y$, is likely to give a good start in the search for a satisfactory value. If the standard deviations vary, the sum of their squares over all the data points could be used. Otherwise experimenting with different values of $S$ will be required from the start, taking account of the remarks in Section 3.

In that case, in view of computation time and memory requirements, it is recommended to start with a very large value for $S$ and so determine the least-squares bicubic polynomial; the value returned for $FP_0$ gives an upper bound for $S$.

Then progressively decrease the value of $S$ to obtain closer fits - say by a factor of 10 in the beginning, i.e., $S=FP_0/10$, $S=FP_0/100$, and so on, and more carefully as the approximation shows more details.

The number of knots of the spline returned, and their location, generally depend on the value of $S$ and on the behaviour of the function underlying the data. However, if E02DCF is called with $\text{START} = 'W'$, the knots returned may also depend on the smoothing factors of the previous calls. Therefore if, after a number of trials with different values of $S$ and $\text{START} = 'W'$, a fit can finally be accepted as satisfactory, it may be worthwhile to call E02DCF once more with the selected value for $S$ but now using $\text{START} = 'C'$. Often, E02DCF then returns an approximation with the
same quality of fit but with fewer knots, which is therefore better if data reduction is also important.

8.4. Choice of NXEST and NYEST

The number of knots may also depend on the upper bounds NXEST and NYEST. Indeed, if at a certain stage in E02DCF the number of knots in one direction (say \( n_x \)) has reached the value of its upper bound (NXEST), then from that moment on all subsequent knots are added in the other (\( y \)) direction. Therefore the user has the option of limiting the number of knots the routine locates in any direction. For example, by setting NXEST = 8 (the lowest allowable value for NXEST), the user can indicate that he wants an approximation which is a simple cubic polynomial in the variable \( x \).

8.5. Outline of Method Used

If \( S=0 \), the requisite number of knots is known in advance, i.e., \( n_x = m + 4 \) and \( n_y = m + 4 \); the interior knots are located immediately as \( (\lambda_i) = x_{i-2} \) and \( (\mu_j) = y_{j-2} \), for \( i = 5, 6, \ldots, n_x - 4 \) and \( j = 5, 6, \ldots, n_y - 4 \). The corresponding least-squares spline is then an \( x \)-interpolating spline and therefore a solution of the problem.

If \( S > 0 \), suitable knot sets are built up in stages (starting with no interior knots in the case of a cold start but with the knot set found in a previous call if a warm start is chosen). At each stage, a bicubic spline is fitted to the data by least-squares, and \( (\theta) \), the sum of squares of residuals, is computed. If \( (\theta) > S \), new knots are added to one knot set or the other so as to reduce \( (\theta) \) at the next stage. The new knots are located in intervals where the fit is particularly poor, their number depending on the value of \( S \) and on the progress made so far in reducing \( (\theta) \). Sooner or later, we find that \( (\theta) \leq S \) and at that point the knot sets are accepted. The routine then goes on to compute the (unique) spline which has these knot sets and which satisfies the full fitting criterion specified by (2) and (3). The theoretical solution has \( (\theta) = S \). The routine computes the spline by an iterative scheme which is ended when \( (\theta) = S \) within a relative tolerance of 0.001. The main part of each iteration consists of a linear least-squares computation of special form, done in a similarly stable and efficient manner as in E02BAF for least-squares curve fitting.

An exception occurs when the routine finds at the start that, even with no interior knots \( (n_x = n_y = 8) \), the least-squares spline
already has its sum of residuals <=S. In this case, since this spline (which is simply a bicubic polynomial) also has an optimal value for the smoothness measure (eta), namely zero, it is returned at once as the (trivial) solution. It will usually mean that S has been chosen too large.

For further details of the algorithm and its use see Dierckx [2].

8.6. Evaluation of Computed Spline

The values of the computed spline at the points (TX(r),TY(r)), for r = 1,2,...,N, may be obtained in the double precision array FF, of length at least N, by the following code:

\[
\begin{align*}
&\text{IFAIL} = 0 \\
&\text{CALL E02DEF}(\text{N}, \text{NX}, \text{NY}, \text{TX}, \text{TY}, \text{LAMDA}, \text{MU}, \text{C}, \text{FF}, \text{WRK}, \text{IWRK}, \text{IFAIL})
\end{align*}
\]

where NX, NY, LAMDA, MU and C are the output parameters of E02DCF, WRK is a double precision workspace array of length at least NY-4, and IWRK is an integer workspace array of length at least NY-4.

To evaluate the computed spline on a KX by KY rectangular grid of points in the x-y plane, which is defined by the x co-ordinates stored in TX(q), for q=1,2,...,KX, and the y co-ordinates stored in TY(r), for r=1,2,...,KY, returning the results in the double precision array FG which is of length at least KX*KY, the following call may be used:

\[
\begin{align*}
&\text{IFAIL} = 0 \\
&\text{CALL E02DFF}(\text{KX}, \text{KY}, \text{NX}, \text{NY}, \text{TX}, \text{TY}, \text{LAMDA}, \text{MU}, \text{C}, \text{FG}, \text{WRK}, \text{LWRK}, * \\
&\text{IWRK}, \text{LIWRK}, \text{IFAIL})
\end{align*}
\]

where NX, NY, LAMDA, MU and C are the output parameters of E02DCF, WRK is a double precision workspace array of length at least LWRK = \text{min}(\text{NWRK1}, \text{NWRK2}) = \text{NWRK1} = \text{KX*4+NX}, \text{NWRK2} = \text{KY*4+NY}, and IWRK is an integer workspace array of length at least LIWRK = \text{KY + NY - 4} if \text{NWRK1} >= \text{NWRK2}, or \text{KX + NX - 4} otherwise. The result of the spline evaluated at grid point (q,r) is returned in element (KY*(q-1)+r) of the array FG.

9. Example

This example program reads in values of MX, MY, x, for q = 1,2,.. r
q
r
ordinates f defined at the grid points (x,y). It then calls q,r q,r
E02DCF to compute a bicubic spline approximation for one
specified value of \( S \), and prints the values of the computed knots and B-spline coefficients. Finally it evaluates the spline at a small sample of points on a rectangular grid.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

---

Bicubic spline approximation to a set of scattered data

--- nage.ht ---

---

--- manpageXXe02ddf ---

---

---

---

---

---
3. Description

This routine determines a smooth bicubic spline approximation \( s(x,y) \) to the set of data points \((x_r, y_r, f_r)\) with weights \( w_r\), for \( r=1,2,...,m \).

The approximation domain is considered to be the rectangle \([x_{\text{min}}, x_{\text{max}}] \times [y_{\text{min}}, y_{\text{max}}]\), where \( x_{\text{min}} \) (\( y_{\text{min}} \)) and \( x_{\text{max}} \) (\( y_{\text{max}} \)) denote the lowest and highest data values of \( x \) (\( y \)).

The spline is given in the B-spline representation

\[
s(x,y) = \sum_{i=1}^{n-4} \sum_{j=1}^{n-4} c_{ij} M(i) N(j),
\]

where \( M(i) \) and \( N(j) \) denote normalised cubic B-splines, the former defined on the knots \((\lambda_1),...,(\lambda_i),...,(\lambda_{i+4})\) and the latter on the knots \((\mu_1),...,(\mu_j),...,(\mu_{j+4})\). For further details, see Hayes and Halliday [4] for bicubic splines and de Boor [1] for normalised B-splines.

The total numbers \( n \) and \( n \) of these knots and their values

\[
\begin{align*}
x_{\text{min}},...,(\lambda_1),...,(\lambda_i),...,(\lambda_{i+4}) \quad \text{and} \quad (\mu_1),...,(\mu_j),...,(\mu_{j+4})
\end{align*}
\]

are chosen automatically by the routine. The knots \((\lambda_1),...,(\lambda_{i+4})\) and \((\mu_1),...,(\mu_{j+4})\) are the interior knots; they divide the approximation domain \([x_{\text{min}}, x_{\text{max}}] \times [y_{\text{min}}, y_{\text{max}}]\) into (}
min max min max
\[ \text{n -7} \times (\text{n -7}) \text{ subpanels } [(\text{lambda}) \times i, i+1] \times [(\text{mu}) \times j, j+1], \]
for i=4,5,...,n-4; j=4,5,...,n-4. Then, much as in the curve x-y case (see E02BEF), the coefficients c_ij are determined as the solution of the following constrained minimization problem:

\[
\text{minimize } \sum_{i,j} (\text{eta})_{ij},
\]
subject to the constraint
\[
\sum_{r=1}^{m-2} \left( (\text{theta})_{r} \right) \leq S - (\text{epsilon})_{r} \leq S
\]
where: (eta) is a measure of the (lack of) smoothness of s(x,y). Its value depends on the discontinuity jumps in s(x,y) across the boundaries of the subpanels. It is zero only when there are no discontinuities and is positive otherwise, increasing with the size of the jumps (see Dierckx [2] for details).

(epsilon) denotes the weighted residual \( w \) \( (f - s(x,y)) \),
and S is a non-negative number to be specified by the user.

By means of the parameter S, 'the smoothing factor', the user will then control the balance between smoothness and closeness of fit, as measured by the sum of squares of residuals in (3). If S is too large, the spline will be too smooth and signal will be lost (underfit); if S is too small, the spline will pick up too much noise (overfit). In the extreme cases the method would return an interpolating spline ((theta)=0) if S were set to zero, and returns the least-squares bicubic polynomial ((eta)=0) if S is set very large. Experimenting with S-values between these two extremes should result in a good compromise. (See Section 8.2 for advice on choice of S.) Note however, that this routine, unlike E02BEF and E02DCF, does not allow S to be set exactly to zero: to compute an interpolant to scattered data, E01SAF or E01SEF should be used.

The method employed is outlined in Section 8.5 and fully described in Dierckx [2] and [3]. It involves an adaptive
strategy for locating the knots of the bicubic spline (depending on the function underlying the data and on the value of S), and an iterative method for solving the constrained minimization problem once the knots have been determined.

Values of the computed spline can subsequently be computed by calling E02DEF or E02DFF as described in Section 8.6.

4. References

5. Parameters

1: START -- CHARACTER*1

Input
On entry: START must be set to 'C' or 'W'.

If START = 'C' (Cold start), the routine will build up the knot set starting with no interior knots. No values need be assigned to the parameters NX, NY, LAMDA, MU or WRK.

If START = 'W' (Warm start), the routine will restart the knot-placing strategy using the knots found in a previous call of the routine. In this case, the parameters NX, NY, LAMDA, MU and WRK must be unchanged from that previous call. This warm start can save much time in searching for a satisfactory value of S. Constraint: START = 'C' or 'W'.

2: M -- INTEGER

Input
On entry: m, the number of data points.

The number of data points with non-zero weight (see W below)
must be at least 16.

3: X(M) -- DOUBLE PRECISION array Input

4: Y(M) -- DOUBLE PRECISION array Input

5: F(M) -- DOUBLE PRECISION array Input
On entry: X(r), Y(r), F(r) must be set to the co-ordinates of (x ,y ,f ), the rth data point, for r=1,2,...,m. The order of the data points is immaterial.

6: W(M) -- DOUBLE PRECISION array Input
On entry: W(r) must be set to w , the rth value in the set of weights, for r=1,2,...,m. Zero weights are permitted and the corresponding points are ignored, except when determining x , x , y and y (see Section 8.4). For advice on the choice of weights, see Section 2.1.2 of the Chapter Introduction. Constraint: the number of data points with non-zero weight must be at least 16.

7: S -- DOUBLE PRECISION Input
On entry: the smoothing factor, S.
For advice on the choice of S, see Section 3 and Section 8.2. Constraint: S > 0.0.

8: NXEST -- INTEGER Input

9: NYEST -- INTEGER Input
On entry: an upper bound for the number of knots n and n required in the x- and y-directions respectively.

In most practical situations, NXEST = NYEST = 4+√m/2 is sufficient. See also Section 8.3. Constraint: NXEST >= 8 and NYEST >= 8.

10: NX -- INTEGER Input/Output
On entry: if the warm start option is used, the value of NX must be left unchanged from the previous call. On exit: the total number of knots, n , of the computed spline with x respect to the x variable.

11: LAMDA(NXEST) -- DOUBLE PRECISION array Input/Output
On entry: if the warm start option is used, the values LAMDA
(1), LAMDA(2),...,LAMDA(NX) must be left unchanged from the
previous call. On exit: LAMDA contains the complete set of
knots (lambda) associated with the x variable, i.e., the
interior knots LAMDA(5), LAMDA(6),...,LAMDA(NX-4) as well as
the additional knots LAMDA(1) = LAMDA(2) = LAMDA(3) = LAMDA
(4) = x and LAMDA(NX-3) = LAMDA(NX-2) = LAMDA(NX-1) =
\min
LAMDA(NX) = x needed for the B-spline representation
\max
(\text{where } x \text{ and } x \text{ are as described in Section 3}).
\min \max

12: NY -- INTEGER
Input/Output
On entry: if the warm start option is used, the value of NY
must be left unchanged from the previous call. On exit: the
total number of knots, n, of the computed spline with
y
respect to the y variable.

13: MU(NYEST) -- DOUBLE PRECISION array
Input/Output
On entry: if the warm start option is used, the values MU(1)
MU(2),...,MU(NY) must be left unchanged from the previous
call. On exit: MU contains the complete set of knots (mu)
i
associated with the y variable, i.e., the interior knots MU
(5), MU(6),...,MU(NY-4) as well as the additional knots MU
(1) = MU(2) = MU(3) = MU(4) = y and MU(NY-3) = MU(NY-2) =
\min
MU(NY-1) = MU(NY) = y needed for the B-spline
\max
representation (\text{where } y \text{ and } y \text{ are as described in min max
\text{Section 3}}).

14: C((NXEST-4)*(NYEST-4)) -- DOUBLE PRECISION array
Output
On exit: the coefficients of the spline approximation. C(
(n-4)*(i-1)+j) is the coefficient c defined in Section 3.
i
\text{y}
j

15: FP -- DOUBLE PRECISION
Output
On exit: the weighted sum of squared residuals, (theta), of
the computed spline approximation. FP should equal S within
a relative tolerance of 0.001 unless NX = NY = 8, when the
spline has no interior knots and so is simply a bicubic
polynomial. For knots to be inserted, S must be set to a
value below the value of FP produced in this case.

16: RANK -- INTEGER
Output
On exit: RANK gives the rank of the system of equations used
to compute the final spline (as determined by a suitable machine-dependent threshold). When \( RANK = (NX-4) \times (NY-4) \), the solution is unique; otherwise the system is rank-deficient and the minimum-norm solution is computed. The latter case may be caused by too small a value of \( S \).

17: \( \text{WRK}(LWRK) \) -- DOUBLE PRECISION array
Workspace
On entry: if the warm start option is used, the value of \( \text{WRK}(1) \) must be left unchanged from the previous call.

This array is used as workspace.

18: \( LWRK \) -- INTEGER Input
On entry:
the dimension of the array \( \text{WRK} \) as declared in the (sub)program from which \( \text{E02DDF} \) is called.
Constraint: \( LWRK \geq (7u+25v)\times(u+1)+2(u+v+4M)+23u+56 \),
where \( u=NXEST-4 \), \( v=NYEST-4 \), and \( w=\max(u,v) \).

For some problems, the routine may need to compute the minimal least-squares solution of a rank-deficient system of linear equations (see Section 3). The amount of workspace required to solve such problems will be larger than specified by the value given above, which must be increased by an amount, \( LWRK2 \) say. An upper bound for \( LWRK2 \) is given by \( 4u+v+u+4v \), where \( u, v \) and \( w \) are as above. However, if there are enough data points, scattered uniformly over the approximation domain, and if the smoothing factor \( S \) is not too small, there is a good chance that this extra workspace is not needed. A lot of memory might therefore be saved by assuming \( LWRK2 = 0 \).

19: \( \text{IWRK}(LIWRK) \) -- INTEGER array
Workspace

20: \( LIWRK \) -- INTEGER Input
On entry:
the dimension of the array \( \text{IWRK} \) as declared in the (sub)program from which \( \text{E02DDF} \) is called.
Constraint: \( LIWRK > M+2*(NXEST-7) \times (NYEST-7) \).

21: \( IFAIL \) -- INTEGER Input/Output
On entry: \( IFAIL \) must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: \( IFAIL = 0 \) unless the routine detects an error (see
6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1
On entry START /= 'C' or 'W',
or the number of data points with non-zero weight < 16,
or S <= 0.0,
or NXEST < 8,
or NYEST < 8,
or LWRK < (7*u*v+25*w)*(w+1)+2*(u+v+4*M)+23*v+56,
where u = NXEST - 4, v = NYEST - 4 and w=max(u,v),
or LIWRK <M+2*(NXEST-7)*(NYEST-7).

IFAIL= 2
On entry either all the X(r), for r = 1,2,...,M, are equal,
or all the Y(r), for r = 1,2,...,M, are equal.

IFAIL= 3
The number of knots required is greater than allowed by NXEST and NYEST. Try increasing NXEST and/or NYEST and, if necessary, supplying larger arrays for the parameters LAMDA, MU, C, WRK and IWRK. However, if NXEST and NYEST are already large, say NXEST, NYEST > 4 + \sqrt{M}/2, then this error exit may indicate that S is too small.

IFAIL= 4
No more knots can be added because the number of B-spline coefficients (NX-4)*(NY-4) already exceeds the number of data points M. This error exit may occur if either of S or M is too small.

IFAIL= 5
No more knots can be added because the additional knot would (quasi) coincide with an old one. This error exit may occur if too large a weight has been given to an inaccurate data
CHAPTER 22. NAG LIBRARY ROUTINES

point, or if \( S \) is too small.

IFAIL= 6
The iterative process used to compute the coefficients of
the approximating spline has failed to converge. This error
exit may occur if \( S \) has been set very small. If the error
persists with increased \( S \), consult NAG.

IFAIL= 7
LWRK is too small; the routine needs to compute the minimal
least-squares solution of a rank-deficient system of linear
equations, but there is not enough workspace. There is no
approximation returned but, having saved the information
contained in NX, LAMDA, NY, MU and WRK, and having adjusted
the value of LWRK and the dimension of array WRK
accordingly, the user can continue at the point the program
was left by calling E02DDF with \( \text{START} = 'W' \). Note that the
requested value for LWRK is only large enough for the
current phase of the algorithm. If the routine is restarted
with LWRK set to the minimum value requested, a larger
request may be made at a later stage of the computation. See
Section 5 for the upper bound on LWRK. On soft failure, the
minimum requested value for LWRK is returned in IWRK(1) and
the safe value for LWRK is returned in IWRK(2).

If IFAIL = 3,4,5 or 6, a spline approximation is returned, but it
fails to satisfy the fitting criterion (see (2) and (3) in
Section 3 -- perhaps only by a small amount, however.

7. Accuracy

On successful exit, the approximation returned is such that its
weighted sum of squared residuals \( FP \) is equal to the smoothing
factor \( S \), up to a specified relative tolerance of 0.001 - except
that if \( n =8 \) and \( n =8 \), \( FP \) may be significantly less than \( S \): in
this case the computed spline is simply the least-squares bicubic
polynomial approximation of degree 3, i.e., a spline with no
interior knots.

8. Further Comments

8.1. Timing

The time taken for a call of E02DDF depends on the complexity of
the shape of the data, the value of the smoothing factor \( S \), and
the number of data points. If E02DDF is to be called for
different values of \( S \), much time can be saved by setting \( \text{START} = 'W' \).
It should be noted that choosing \( S \) very small considerably
increases computation time.
8.2. Choice of S

If the weights have been correctly chosen (see Section 2.1.2 of the Chapter Introduction), the standard deviation of \( w_f \) would be the same for all \( r \), equal to \( (\sigma) \), say. In this case, choosing the smoothing factor \( S \) in the range \( (\sigma) (m-\sqrt{2m}) \), as suggested by Reinsch [6], is likely to give a good start in the search for a satisfactory value. Otherwise, experimenting with different values of \( S \) will be required from the start.

In that case, in view of computation time and memory requirements, it is recommended to start with a very large value for \( S \) and so determine the least-squares bicubic polynomial; the value returned for FP, call it \( FP_0 \), gives an upper bound for \( S \).

Then progressively decrease the value of \( S \) to obtain closer fits - say by a factor of 10 in the beginning, i.e., \( S=FP_0 /10 \), \( S=FP_0 /100 \), and so on, and more carefully as the approximation shows more details.

To choose \( S \) very small is strongly discouraged. This considerably increases computation time and memory requirements. It may also cause rank-deficiency (as indicated by the parameter RANK) and endanger numerical stability.

The number of knots of the spline returned, and their location, generally depend on the value of \( S \) and on the behaviour of the function underlying the data. However, if E02DDF is called with \( \text{START} = 'W' \), the knots returned may also depend on the smoothing factors of the previous calls. Therefore if, after a number of trials with different values of \( S \) and \( \text{START} = 'W' \), a fit can finally be accepted as satisfactory, it may be worthwhile to call E02DDF once more with the selected value for \( S \) but now using \( \text{START} = 'C' \). Often, E02DDF then returns an approximation with the same quality of fit but with fewer knots, which is therefore better if data reduction is also important.

8.3. Choice of NXEST and NYEST

The number of knots may also depend on the upper bounds NXEST and NYEST. Indeed, if at a certain stage in E02DDF the number of knots in one direction (say \( n_x \)) has reached the value of its upper bound (NXEST), then from that moment on all subsequent knots are added in the other (\( y \)) direction. This may indicate...
that the value of NXEST is too small. On the other hand, it gives
the user the option of limiting the number of knots the routine
locates in any direction. For example, by setting NXEST = 8 (the
lowest allowable value for NXEST), the user can indicate that he
wants an approximation which is a simple cubic polynomial in the
variable x.

8.4. Restriction of the approximation domain

The fit obtained is not defined outside the rectangle
\[(\lambda_\text{min}, \lambda_\text{max}) \times (\mu_\text{min}, \mu_\text{max})\]. The reason for taking
\[
\begin{align*}
\lambda_\text{min} + (4n-3)/4 & \quad \lambda_\text{max} - (n-3)/4 \\
\mu_\text{min} + (4n-3)/4 & \quad \mu_\text{max} - (n-3)/4
\end{align*}
\]
the extreme data values of x and y for these four knots is that,
as is usual in data fitting, the fit cannot be expected to give
satisfactory values outside the data region. If, nevertheless,
the user requires values over a larger rectangle, this can be
achieved by augmenting the data with two artificial data points
\((a,c,0)\) and \((b,d,0)\) with zero weight, where \([a,b] * [c,d]\) denotes
the enlarged rectangle.

8.5. Outline of method used

First suitable knot sets are built up in stages (starting with no
interior knots in the case of a cold start but with the knot set
found in a previous call if a warm start is chosen). At each
stage, a bicubic spline is fitted to the data by least-squares
and \((\theta)\), the sum of squares of residuals, is computed. If
\((\theta) > S\), a new knot is added to one knot set or the other so as
to reduce \((\theta)\) at the next stage. The new knot is located in
an interval where the fit is particularly poor. Sooner or later,
we find that \((\theta) \leq S\) and at that point the knot sets are
accepted. The routine then goes on to compute a spline which has
these knot sets and which satisfies the full fitting criterion
specified by (2) and (3). The theoretical solution has \((\theta) = S\).
The routine computes the spline by an iterative scheme which is
ended when \((\theta) = S\) within a relative tolerance of 0.001. The
main part of each iteration consists of a linear least-squares
computation of special form, done in a similarly stable and
efficient manner as in E02DAF. As there also, the minimal least-
squares solution is computed wherever the linear system is found
to be rank-deficient.

An exception occurs when the routine finds at the start that,
even with no interior knots \((N = 8)\), the least-squares spline
already has its sum of squares of residuals \(\leq S\). In this case,
since this spline (which is simply a bicubic polynomial) also has
an optimal value for the smoothness measure \((\eta)\), namely zero,
it is returned at once as the (trivial) solution. It will usually
mean that \(S\) has been chosen too large.
For further details of the algorithm and its use see Dierckx [2].

8.6. Evaluation of computed spline

The values of the computed spline at the points (TX(r),TY(r)), for r = 1,2,...,N, may be obtained in the double precision array FF, of length at least N, by the following code:

IFAIL = 0
CALL E02DEF(N,NX,NY,TX,TY,LAMDA,MU,C,FF,WRK,IWRK,IFAIL)

where NX, NY, LAMDA, MU and C are the output parameters of E02DDF, WRK is a double precision workspace array of length at least NY-4, and IWRK is an integer workspace array of length at least NY-4.

To evaluate the computed spline on a KX by KY rectangular grid of points in the x-y plane, which is defined by the x co-ordinates stored in TX(q), for q=1,2,...,KX, and the y co-ordinates stored in TY(r), for r=1,2,...,KY, returning the results in the double precision array FG which is of length at least KX*KY, the following call may be used:

IFAIL = 0
CALL E02DFF(KX,KY,NX,NY,TX,TY,LAMDA,MU,C,FG,WRK,LWRK,*
  IWRK,LIWRK,IFAIL)

where NX, NY, LAMDA, MU and C are the output parameters of E02DDF, WRK is a double precision workspace array of length at least LWRK = min(NWRK1,NWRK2), NWRK1 = KX*4+NX, NWRK2 = KY*4+NY, and IWRK is an integer workspace array of length at least LIWRK = KY + NY - 4 if NWRK1 >= NWRK2, or KX + NX - 4 otherwise. The result of the spline evaluated at grid point (q,r) is returned in element (KY*(q-1)+r) of the array FG.

9. Example

This example program reads in a value of M, followed by a set of M data points (x ,y ,f ) and their weights w . It then calls E02DDF to compute a bicubic spline approximation for one specified value of S, and prints the values of the computed knots and B-spline coefficients. Finally it evaluates the spline at a small sample of points on a rectangular grid.
The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
This routine calculates values of the bicubic spline \( s(x,y) \) at prescribed points \((x_r,y_r)\), for \( r=1,2,\ldots,m \), from its augmented knot sets \((\lambda)\) and \((\mu)\) and from the coefficients \(c_{ij}\) for \( i=1,2,\ldots,\text{PX}-4; j=1,2,\ldots,\text{PY}-4 \), in its B-spline representation
\[
- \quad s(x,y) = \sum_{i,j} c_{ij} M_i(x)N_j(y). 
- \quad ij \quad ij
\]
Here \( M_i(x) \) and \( N_j(y) \) denote normalised cubic B-splines, the former defined on the knots \((\lambda)\) to \((\lambda)\) and the latter on the knots \((\mu)\) to \((\mu)\).

This routine may be used to calculate values of a bicubic spline given in the form produced by E01DAF, E02DAF, E02DCF and E02DDF. It is derived from the routine B2VRE in Anthony et al [1].

4. References

5. Parameters

1: \( M \) -- INTEGER
\( \quad \) Input
On entry: \( m \), the number of points at which values of the spline are required. Constraint: \( M \geq 1 \).

2: \( \text{PX} \) -- INTEGER
\( \quad \) Input

3: \( \text{PY} \) -- INTEGER
\( \quad \) Input
On entry: \( \text{PX} \) and \( \text{PY} \) must specify the total number of knots associated with the variables \( x \) and \( y \) respectively. They are such that \( \text{PX}-8 \) and \( \text{PY}-8 \) are the corresponding numbers of interior knots. Constraint: \( \text{PX} \geq 8 \) and \( \text{PY} \geq 8 \).

4: \( X(M) \) -- DOUBLE PRECISION array
\( \quad \) Input

5: \( Y(M) \) -- DOUBLE PRECISION array
\( \quad \) Input
On entry: X and Y must contain \( x \) and \( y \), for \( r=1,2,\ldots,m \), respectively. These are the co-ordinates of the points at which values of the spline are required. The order of the points is immaterial. Constraint: X and Y must satisfy
\[
\text{LAMDA}(4) \leq X(r) \leq \text{LAMDA}(\text{PX}-3)
\]
and
\[
\text{MU}(4) \leq Y(r) \leq \text{MU}(\text{PY}-3), \text{ for } r=1,2,\ldots,m.
\]
The spline representation is not valid outside these intervals.

6: LAMDA(PX) -- DOUBLE PRECISION array Input

7: MU(PY) -- DOUBLE PRECISION array Input
On entry: LAMDA and MU must contain the complete sets of knots \{\text{LAMDA}\} and \{\text{MU}\} associated with the x and y variables respectively. Constraint: the knots in each set must be in non-decreasing order, with LAMDA(PX-3) > LAMDA(4) and MU(PY-3) > MU(4).

8: C((PX-4)*(PY-4)) -- DOUBLE PRECISION array Input
On entry: \( C((\text{PY}-4)\*(i-1)+j) \) must contain the coefficient \( c_{ij} \) described in Section 3, for \( i=1,2,\ldots,\text{PX}-4; j=1,2,\ldots,\text{PY}-4 \).

9: FF(M) -- DOUBLE PRECISION array Output
On exit: FF(r) contains the value of the spline at the point \( (x ,y ) \), for \( r=1,2,\ldots,m \).

10: WRK(PY-4) -- DOUBLE PRECISION array Workspace

11: IWRK(PY-4) -- INTEGER array Workspace

12: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:
If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL = 1
  On entry M < 1,
    or PY < 8,
    or PX < 8.

IFAIL = 2
  On entry the knots in array LAMDA, or those in array MU, are not in non-decreasing order, or LAMDA(PX-3) <= LAMDA(4), or MU(PY-3) <= MU(4).

IFAIL = 3
  On entry at least one of the prescribed points (x , y ) lies
    r r
  outside the rectangle defined by LAMDA(4), LAMDA(PX-3) and
    r
  MU(4), MU(PY-3).

7. Accuracy

The method used to evaluate the B-splines is numerically stable, in the sense that each computed value of s(x , y ) can be regarded
    r r
as the value that would have been obtained in exact arithmetic from slightly perturbed B-spline coefficients. See Cox [2] for details.

8. Further Comments

Computation time is approximately proportional to the number of points, m, at which the evaluation is required.

9. Example

This program reads in knot sets LAMDA(1),..., LAMDA(PX) and MU(1),..., MU(PY), and a set of bicubic spline coefficients c .

Following these are a value for m and the co-ordinates (x , y ),
    r r
for r=1,2,...,m, at which the spline is to be evaluated.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

\end{verbatim}
Calculates values of a bicubic spline from B-spline representation

1. Purpose

E02DFF calculates values of a bicubic spline from its B-spline representation. The spline is evaluated at all points on a rectangular grid.

2. Specification

```fortran
SUBROUTINE E02DFF (MX, MY, PX, PY, X, Y, LAMDA, MU, C, FF, WRK, LWRK, IWRK(LIWRK), LIWRK, IFAIL)
INTEGER MX, MY, PX, PY, LAMDA, MU, C, LIWRK(LIWRK), LIWRK, IWRK(LIWRK), IFAIL
DOUBLE PRECISION X(MX), Y(MY), LAMDA(PX), MU(PY), C((PX-4)*PY-4)), FF(MX*MY), WRK(LWRK)
```

3. Description

This routine calculates values of the bicubic spline \( s(x,y) \) on a rectangular grid of points in the \( x-y \) plane, from its augmented knot sets \( \{(\lambda)\} \) and \( \{(\mu)\} \) and from the coefficients \( c \),
for \( i=1,2,\ldots,\text{PX}-4; j=1,2,\ldots,\text{PY}-4 \), in its B-spline representation

\[
\begin{align*}
\text{s}(x,y) &= \sum_{ij} c_{ij} M_i(x) N_j(y) \\
\end{align*}
\]

Here \( M_i(x) \) and \( N_j(y) \) denote normalised cubic B-splines, the former defined on the knots \((\lambda_i, \lambda_{i+4})\) and the latter on the knots \((\mu_j, \mu_{j+4})\).

The points in the grid are defined by co-ordinates \( x_q \), for \( q=1,2,\ldots,\text{m} \), along the \( x \) axis, and co-ordinates \( y_r \), for \( r=1,2,\ldots,\text{m} \), along the \( y \) axis.

This routine may be used to calculate values of a bicubic spline given in the form produced by E01DAF, E02DAF, E02DCF and E02DDF. It is derived from the routine B2VRE in Anthony et al [1].

4. References

5. Parameters

1: \( \text{MX} -- \text{INTEGER} \) Input

2: \( \text{MY} -- \text{INTEGER} \) Input

\( \text{On entry: MX and MY must specify } \text{m} \text{ and } \text{m} \text{ respectively, } x_y \text{ the number of points along the } x \text{ and } y \text{ axis that define the rectangular grid. Constraint: } \text{MX} \geq 1 \text{ and } \text{MY} \geq 1. \)

3: \( \text{PX} -- \text{INTEGER} \) Input

4: \( \text{PY} -- \text{INTEGER} \) Input

\( \text{On entry: PX and PY must specify the total number of knots} \)
associated with the variables $x$ and $y$ respectively. They are such that $PX - 8$ and $PY - 8$ are the corresponding numbers of interior knots. Constraint: $PX \geq 8$ and $PY \geq 8$.

5: $X(MX)$ -- DOUBLE PRECISION array
Input

6: $Y(MY)$ -- DOUBLE PRECISION array
On entry: $X$ and $Y$ must contain $x$, for $q=1,2,\ldots,m$, and $y$, for $r=1,2,\ldots,m$, respectively. These are the $x$ and $y$ coordinates that define the rectangular grid of points at which values of the spline are required. Constraint: $X$ and $Y$ must satisfy

$$LAMDA(4) \leq X(q) < X(q+1) \leq LAMDA(PX-3), \text{ for } q=1,2,\ldots,m-1$$

and

$$MU(4) \leq Y(r) < Y(r+1) \leq MU(PY-3), \text{ for } r=1,2,\ldots,m-1.$$  

The spline representation is not valid outside these intervals.

7: $LAMDA(PX)$ -- DOUBLE PRECISION array
Input

8: $MU(PY)$ -- DOUBLE PRECISION array
Input
On entry: $LAMDA$ and $MU$ must contain the complete sets of knots $\{(\lambda)\}$ and $\{(\mu)\}$ associated with the $x$ and $y$ variables respectively. Constraint: the knots in each set must be in non-decreasing order, with $LAMDA(PX-3) > LAMDA(4)$ and $MU(PY-3) > MU(4)$.

9: $C((PX-4)*(PY-4))$ -- DOUBLE PRECISION array
Input
On entry: $C((PY-4)*(i-1)+j)$ must contain the coefficient $c$ described in Section 3, for $i=1,2,\ldots,PX-4$; $j=1,2,\ldots,PY-4$.

10: $FF(MX*MY)$ -- DOUBLE PRECISION array
Output
On exit: $FF(MY*(q-1)+r)$ contains the value of the spline at the point $(x,y)$, for $q=1,2,\ldots,m$; $r=1,2,\ldots,m$.

11: $WRK(LWRK)$ -- DOUBLE PRECISION array
Workspace

12: $LWRK$ -- INTEGER
Input
On entry: the dimension of the array $WRK$ as declared in the
(sub)program from which E02DFF is called.
Constraint: LWRK >= min(NWRK1,NWRK2), where NWRK1=4*MX+PX,
NWRK2=4*MY+PY.

13: IWRK(LIWRK) -- INTEGER array Workspace

14: LIWRK -- INTEGER Input
On entry:
the dimension of the array IWRK as declared in the
(sub)program from which E02DFF is called.
Constraint: LIWRK >= MY + PY - 4 if NWRK1 > NWRK2, or MX + PX - 4 otherwise, where NWRK1 and NWRK2 are as defined in the description of argument LWRK.

15: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1
On entry MX < 1,
 or MY < 1,
 or PY < 8,
 or PX < 8.

IFAIL= 2
On entry LWRK is too small,
 or LIWRK is too small.

IFAIL= 3
On entry the knots in array LAMDA, or those in array MU, are not in non-decreasing order, or LAMDA(PX-3) <= LAMDA(4), or MU(PY-3) <= MU(4).

IFAIL= 4
On entry the restriction LAMDA(4) <= X(1) <... < X(MX) <=
LAMDA(PX-3), or the restriction MU(4) <= Y(1) < ... < Y(MY)
<= MU(PY-3), is violated.

7. Accuracy

The method used to evaluate the B-splines is numerically stable,
in the sense that each computed value of \( s(x, y) \) can be regarded
as the value that would have been obtained in exact arithmetic
from slightly perturbed B-spline coefficients. See Cox [2] for
details.

8. Further Comments

Computation time is approximately proportional to \( m^2 + 4(m + m) \).

9. Example

This program reads in knot sets LAMDA(1),..., LAMDA(PX) and MU(1)
..., MU(PY), and a set of bicubic spline coefficients \( c_{ij} \).
Following these are values for \( m \) and the x co-ordinates \( x_q \), for
\( q=1,2,...,m \), and values for \( m \) and the y co-ordinates \( y_r \), for
\( r=1,2,...,m \), defining the grid of points on which the spline is
\( y \) to be evaluated.

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.

---

Calculates \( l_1 \) solution to over-determined system equations

— nage.ht —
Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E02GAF calculates an l solution to an over-determined system of linear equations.

2. Specification

SUBROUTINE E02GAF (M, A, LA, B, NPLUS2, TOLER, X, RESID, IRANK, ITER, IWORK, IFAIL)

INTEGER M, LA, NPLUS2, IRANK, ITER, IWORK(M), IFAIL
DOUBLE PRECISION A(LA,NPLUS2), B(M), TOLER, X(NPLUS2), RESID

3. Description

Given a matrix A with m rows and n columns (m\geq n) and a vector b with m elements, the routine calculates an l solution to the over-determined system of equations

Ax=b.

That is to say, it calculates a vector x, with n elements, which minimizes the l-norm (the sum of the absolute values) of the residuals

\[ r(x) = \sum_{i=1}^{m} |r_i|, \]

with the symbol (*).
where the residuals $r$ are given by

$$\begin{align*}
    r &= b - \sum_{i=1}^{m} a_{ij} x_i, \\
    i &= 1, 2, \ldots, m. \\
    j &= 1
\end{align*}$$

Here $a_{ij}$ is the element in row $i$ and column $j$ of $A$, $b_i$ is the $i$th element of $b$, and $x_j$ the $j$th element of $x$. The matrix $A$ need not be of full rank.

Typically in applications to data fitting, data consisting of $m$ points with co-ordinates $(t_i, y_i)$ are to be approximated in the $l_1$-norm by a linear combination of known functions $(\phi_i)(t)$,

$$(\alpha_1)(\phi_1)(t_1) + (\alpha_2)(\phi_2)(t_2) + \ldots + (\alpha_n)(\phi_n)(t_n).$$

This is equivalent to fitting an $l_1$ solution to the over-determined system of equations

$$\begin{align*}
    n \\
    &> (\phi_i)(t_j)(\alpha) = y_i, \\
    i &= 1, 2, \ldots, m. \\
    j &= 1
\end{align*}$$

Thus if, for each value of $i$ and $j$, the element $a_{ij}$ of the matrix $A$ in the previous paragraph is set equal to the value of $(\phi_i)(t_j)$ and $b_i$ is set equal to $y_i$, the solution vector $x$ will contain the required values of the $(\alpha_i)$. Note that the independent variable $t$ above can, instead, be a vector of several independent variables (this includes the case where each $(\phi_i)$ is a function of a different variable, or set of variables).

The algorithm is a modification of the simplex method of linear programming applied to the primal formulation of the $l_1$ problem (see Barrodale and Roberts [1] and [2]). The modification allows
several neighbouring simplex vertices to be passed through in a single iteration, providing a substantial improvement in efficiency.

4. References

5. Parameters

1: M -- INTEGER Input
On entry: the number of equations, $m$ (the number of rows of the matrix $A$). Constraint: $M \geq n \geq 1$.

2: A(LA,NPLUS2) -- DOUBLE PRECISION array Input/Output
On entry: $A(i,j)$ must contain $a_{ij}$, the element in the $i$th row and $j$th column of the matrix $A$, for $i=1,2,\ldots,m$ and $j=1,2,\ldots,n$. The remaining elements need not be set. On exit: $A$ contains the last simplex tableau generated by the simplex method.

3: LA -- INTEGER Input
On entry: the first dimension of the array $A$ as declared in the (sub)program from which E02GAF is called. Constraint: $LA \geq M + 2$.

4: B(M) -- DOUBLE PRECISION array Input/Output
On entry: $b_i$, the $i$th element of the vector $b$, for $i=1,2,\ldots,m$. On exit: the $i$th residual $r_i$ corresponding to the solution vector $x$, for $i=1,2,\ldots,m$.

5: NPLUS2 -- INTEGER Input
On entry: $n+2$, where $n$ is the number of unknowns (the number of columns of the matrix $A$). Constraint: $3 \leq NPLUS2 \leq M + 2$.

6: TOLER -- DOUBLE PRECISION Input
On entry: a non-negative value. In general TOLER specifies
a threshold below which numbers are regarded as zero. The recommended threshold value is (epsilon) where (epsilon) is the machine precision. The recommended value can be computed within the routine by setting TOLER to zero. If premature termination occurs a larger value for TOLER may result in a valid solution. Suggested value: 0.0.

7: X(NPLUS2) -- DOUBLE PRECISION array Output
On exit: X(j) contains the jth element of the solution vector x, for j=1,2,...,n. The elements X(n+1) and X(n+2) are unused.

8: RESID -- DOUBLE PRECISION Output
On exit: the sum of the absolute values of the residuals for the solution vector x.

9: IRANK -- INTEGER Output
On exit: the computed rank of the matrix A.

10: ITER -- INTEGER Output
On exit: the number of iterations taken by the simplex method.

11: IWORK(M) -- INTEGER array Workspace

12: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
An optimal solution has been obtained but this may not be unique.

IFAIL= 2
The calculations have terminated prematurely due to rounding errors. Experiment with larger values of TOLER or try scaling the columns of the matrix (see Section 8).

IFAIL= 3
On entry NPLUS2 < 3,
or \( NPLUS2 > M + 2 \),

or \( LA < M + 2 \).

7. Accuracy

Experience suggests that the computational accuracy of the solution \( x \) is comparable with the accuracy that could be obtained by applying Gaussian elimination with partial pivoting to the \( n \) equations satisfied by this algorithm (i.e., those equations with zero residuals). The accuracy therefore varies with the conditioning of the problem, but has been found generally very satisfactory in practice.

8. Further Comments

The effects of \( m \) and \( n \) on the time and on the number of iterations in the Simplex Method vary from problem to problem, but typically the number of iterations is a small multiple of \( n \) and the total time taken by the routine is approximately

\[
2 \propto mn.
\]

It is recommended that, before the routine is entered, the columns of the matrix \( A \) are scaled so that the largest element in each column is of the order of unity. This should improve the conditioning of the matrix, and also enable the parameter \( TOLER \) to perform its correct function. The solution \( x \) obtained will then, of course, relate to the scaled form of the matrix. Thus if the scaling is such that, for each \( j=1,2,...,n \), the elements of the \( j \)th column are multiplied by the constant \( k \), the element \( x^j \) of the solution vector \( x \) must be multiplied by \( k \) if it is desired to recover the solution corresponding to the original matrix \( A \).

9. Example

Suppose we wish to approximate a set of data by a curve of the form

\[
y = Ke^{t} + Le^{-t} + M
\]

where \( K \), \( L \) and \( M \) are unknown. Given values \( y \) at 5 points \( t \) we may form the over-determined set of equations for \( K \), \( L \) and \( M \)

\[
x - x
\]

3. Description

A set of \( m \) data points with rectangular Cartesian co-ordinates \( x, y \) are sorted into panels defined by lines parallel to the \( y \) and \( x \) axes. The intercepts of these lines on the \( x \) and \( y \) axes are given in \( \text{LAMDA}(i) \), for \( i=5,6,...,\text{PX}-4 \) and \( \text{MU}(j) \), for \( j=5,6,...,\text{PY}-4 \), respectively. The subroutine orders the data so that all points in a panel occur before data in succeeding panels, where the panels are numbered from bottom to top and then left to right, with the usual arrangement of axes, as shown in the diagram. Within a panel the points maintain their original order.

Please see figure in printed Reference Manual

A data point lying exactly on one or more panel sides is taken to be in the highest-numbered panel adjacent to the point. The subroutine does not physically rearrange the data, but provides the array \( \text{POINT} \) which contains a linked list for each panel, pointing to the data in that panel. The total number of panels is \((\text{PX}-7)\times(\text{PY}-7)\).

4. References

None.

5. Parameters

1: \( \text{PX} \) -- INTEGER Input

On entry: \( \text{PX} \) and \( \text{PY} \) must specify eight more than the number of intercepts on the \( x \) axis and \( y \) axis, respectively.

Constraint: \( \text{PX} \geq 8 \) and \( \text{PY} \geq 8 \).

2: \( \text{PY} \) -- INTEGER Input

3: \( \text{LAMDA}(\text{PX}) \) -- DOUBLE PRECISION array Input

On entry: \( \text{LAMDA}(5) \) to \( \text{LAMDA}((\text{PX}-4)) \) must contain, in non-decreasing order, the intercepts on the \( x \) axis of the sides of the panels parallel to the \( y \) axis.

4: \( \text{MU}(\text{PY}) \) -- DOUBLE PRECISION array Input

On entry: \( \text{MU}(5) \) to \( \text{MU}((\text{PY}-4)) \) must contain, in non-decreasing order, the intercepts on the \( y \) axis of the sides of the panels parallel to the \( x \) axis.
5: M -- INTEGER Input
   On entry: the number m of data points.

6: X(M) -- DOUBLE PRECISION array Input

7: Y(M) -- DOUBLE PRECISION array Input
   On entry: the co-ordinates of the rth data point $(x_r, y_r)$,
   for $r = 1, 2, \ldots, m$.

8: POINT(NPOINT) -- INTEGER array Output
   On exit: for $i = 1, 2, \ldots, \text{NADRES}$, POINT(m+i) = I1 is the
   index of the first point in panel i, POINT(I1) = I2 is the
   index of the second point in panel i and so on.

   POINT(IN) = 0 indicates that $X(IN), Y(IN)$ was the last point
   in the panel.

   The co-ordinates of points in panel i can be accessed in
   turn by means of the following instructions:
   
   \[
   \begin{align*}
   \text{IN} &= M + I \\
   \text{IN} &= \text{POINT}(	ext{IN}) \\
   \text{IF} (\text{IN} \text{EQ} 0) & \text{GOTO} 20 \\
   \text{XI} &= X(\text{IN}) \\
   \text{YI} &= Y(\text{IN}) \\
   \ldots & \\
   & \text{GOTO} 10 \\
   \end{align*}
   \]

9: NPOINT -- INTEGER Input
   On entry:
   the dimension of the array POINT as declared in the
   (sub)program from which E02ZAF is called.
   Constraint: NPOINT $\geq$ M + (PX-7)*(PY-7).

10: ADRES(NADRES) -- INTEGER array Workspace

11: NADRES -- INTEGER Input
   On entry: the value $(\text{PX}-7) \times (\text{PY}-7)$, the number of panels
   into which the $(x,y)$ plane is divided.

12: IFAIL -- INTEGER Input/Output
   On entry: IFAIL must be set to 0, -1 or 1. For users not
   familiar with this parameter (described in the Essential
   Introduction) the recommended value is 0.

   On exit: IFAIL = 0 unless the routine detects an error (see
6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL = 1
The intercepts in the array LAMDA, or in the array MU, are not in non-decreasing order.

IFAIL = 2
On entry PX < 8, or PY < 8, or M <= 0, or NADRES /= (PX-7)*(PY-7), or NPOINT < M + (PX-7)*(PY-7).

7. Accuracy

Not applicable.

8. Further Comments

The time taken by this routine is approximately proportional to m log(NADRES).

This subroutine was written to sort two dimensional data in the manner required by routines E02DAF and E02DBF(*). The first 9 parameters of E02ZAF are the same as the parameters in E02DAF and E02DBF(*) which have the same name.

9. Example

This example program reads in data points and the intercepts of the panel sides on the x and y axes; it calls E02ZAF to set up the index array POINT; and finally it prints the data points in panel order.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

1. Scope of the Chapter

An optimization problem involves minimizing a function (called the objective function) of several variables, possibly subject to restrictions on the values of the variables defined by a set of constraint functions. The routines in the NAG Foundation Library are concerned with function minimization only, since the problem of maximizing a given function can be transformed into a minimization problem simply by multiplying the function by -1.

This introduction is only a brief guide to the subject of optimization designed for the casual user. Anyone with a difficult or protracted problem to solve will find it beneficial to consult a more detailed text, such as Gill et al [5] or Fletcher [3].

Readers who are unfamiliar with the mathematics of the subject may find some sections difficult at first reading; if so, they should concentrate on Sections 2.1, 2.2, 2.5, 2.6 and 3.

2. Background to the Problems

2.1. Types of Optimization Problems

Solution of optimization problems by a single, all-purpose, method is cumbersome and inefficient. Optimization problems are therefore classified into particular categories, where each category is defined by the properties of the objective and constraint functions, as illustrated by some examples below.

<table>
<thead>
<tr>
<th>Properties of Objective Function</th>
<th>Properties of Constraints</th>
</tr>
</thead>
<tbody>
<tr>
<td>Nonlinear</td>
<td>Nonlinear</td>
</tr>
<tr>
<td>Sums of squares of nonlinear functions</td>
<td>Sparse linear</td>
</tr>
<tr>
<td>Quadratic</td>
<td>Linear</td>
</tr>
<tr>
<td>Sums of squares of linear bounds functions</td>
<td>None</td>
</tr>
</tbody>
</table>

For instance, a specific problem category involves the minimization of a nonlinear objective function subject to bounds on the variables. In the following sections we define the
particular categories of problems that can be solved by routines contained in this Chapter.

2.1.1. Unconstrained minimization

In unconstrained minimization problems there are no constraints on the variables. The problem can be stated mathematically as follows:

\[
\text{minimize } F(x) \\
\quad x
\]

where \( x \) is in \( \mathbb{R} \), that is, \( x = (x_1, x_2, \ldots, x_n) \).

2.1.2. Nonlinear least-squares problems

Special consideration is given to the problem for which the function to be minimized can be expressed as a sum of squared functions. The least-squares problem can be stated mathematically as follows:

\[
\begin{align*}
\text{minimize } & \{ f_i(x) \}, \quad x \text{ is in } \mathbb{R} \\
\text{subject to } & \{ \quad i=1 \}
\end{align*}
\]

where the \( i \)-th element of the \( m \)-vector \( f \) is the function \( f_i(x) \).

2.1.3. Minimization subject to bounds on the variables

These problems differ from the unconstrained problem in that at least one of the variables is subject to a simple restriction on its value, e.g. \( x \leq 10 \), but no constraints of a more general form are present.

The problem can be stated mathematically as follows:

\[
\begin{align*}
\text{minimize } & F(x), \quad x \text{ is in } \mathbb{R} \\
\text{subject to } & l_i \leq x_i \leq u_i, \quad i=1,2,\ldots,n.
\end{align*}
\]

This format assumes that upper and lower bounds exist on all the
variables. By conceptually allowing \( u = \infty \) and \( l = -\infty \) all

the variables need not be restricted.

2.1.4. Minimization subject to linear constraints

A general linear constraint is defined as a constraint function

that is linear in more than one of the variables, e.g. \( 3x_1 + 2x_2 \geq 4 \)

The various types of linear constraint are reflected in the

following mathematical statement of the problem:

\[
\begin{align*}
& \text{minimize } F(x), \ x \text{ is in } \mathbb{R}^n \\
& \text{subject to the} \\
\end{align*}
\]

\[
\begin{align*}
\text{equality} & \quad a_i^T x = b_i, \quad i = 1, 2, \ldots, m; \\
\text{constraints:} & \quad i \quad i \quad 1 \\
\text{inequality} & \quad a_i^T x \geq b_i, \quad i = m + 1, m + 2, \ldots, m; \\
\text{constraints:} & \quad i \quad i \quad 1 \quad 1 \quad 2 \\
\text{inequality} & \quad a_i^T x \leq b_i, \quad i = m + 1, m + 2, \ldots, m; \\
\text{constraints:} & \quad i \quad i \quad 2 \quad 2 \quad 3 \\
\text{range} & \quad s \leq a_i^T x \leq t_i, \quad i = m + 1, m + 2, \ldots, m; \\
\text{constraints:} & \quad j \quad i \quad j \quad 3 \quad 3 \quad 4 \\
& \quad j = 1, 2, \ldots, m - m; \\
& \quad 4 \quad 3 \\
\text{bounds} & \quad 1 \leq x \leq u_i, \quad i = 1, 2, \ldots, n \\
\text{constraints:} & \quad i \quad i \quad i
\end{align*}
\]

where each \( a_i \) is a vector of length \( n \); \( b_i \), \( s \) and \( t_i \) are constant

scalars; and any of the categories may be empty.

Although the bounds on \( x \) could be included in the definition of

general linear constraints, we prefer to distinguish between them

for reasons of computational efficiency.

If \( F(x) \) is a linear function, the linearly-constrained problem is
termed a linear programming problem (LP problem); if \( F(x) \) is a quadratic function, the problem is termed a quadratic programming problem (QP problem). For further discussion of LP and QP problems, including the dual formulation of such problems, see Dantzig \[2\].

2.1.5. Minimization subject to nonlinear constraints

A problem is included in this category if at least one constraint function is nonlinear, e.g. \( x + x + x - 2 \geq 0 \). The mathematical statement of the problem is identical to that for the linearly-constrained case, except for the addition of the following constraints:

\[
\begin{align*}
& \text{equality constraints: } \quad c_i(x) = 0, \quad i = 1, 2, \ldots, m; \\
& \text{inequality constraints: } \quad c_i(x) \geq 0, \quad i = m + 1, m + 2, \ldots, m; \\
& \text{range constraints: } \quad v_i \leq c_j(x) \leq w_j, \quad j = 1, 2, \ldots, m - m
\end{align*}
\]

where each \( c_i \) is a nonlinear function; \( v_i \) and \( w_j \) are constant scalars; and any category may be empty. Note that we do not include a separate category for constraints of the form \( c_i(x) \leq 0 \), since this is equivalent to \( -c_i(x) \geq 0 \).

2.2. Geometric Representation and Terminology

To illustrate the nature of optimization problems it is useful to consider the following example in two dimensions

\[
F(x) = e^{(4x + 2x + 4x x + 2x + 1)}.
\]

(This function is used as the example function in the documentation for the unconstrained routines.)

Figure 1
Figure 1 is a contour diagram of $F(x)$. The contours labelled $F_0, F_1, \ldots, F_4$ are isovalue contours, or lines along which the function $F(x)$ takes specific constant values. The point $x$ is a local unconstrained minimum, that is, the value of $F(x)$ is less than at all the neighbouring points. A function may have several such minima. The lowest of the local minima is termed a global minimum. In the problem illustrated in Figure 1, $x$ is the only local minimum. The point $x$ is said to be a saddle point because it is a minimum along the line $AB$, but a maximum along $CD$.

If we add the constraint $x \geq 0$ to the problem of minimizing $F(x)$, the solution remains unaltered. In Figure 1 this constraint is represented by the straight line passing through $x = 0$, and the shading on the line indicates the unacceptable region. The region in $\mathbb{R}^n$ satisfying the constraints of an optimization problem is termed the feasible region. A point satisfying the constraints is defined as a feasible point.

If we add the nonlinear constraint $x + x - x - 1.5 \geq 0$, represented by the curved shaded line in Figure 1, then $x$ is not a feasible point. The solution of the new constrained problem is $x$, the feasible point with the smallest function value.

2.2.1. Gradient vector

The vector of first partial derivatives of $F(x)$ is called the gradient vector, and is denoted by $g(x)$, i.e.,

$$
\begin{bmatrix}
\frac{dF(x)}{dx} & \frac{dF(x)}{dx} & \cdots & \frac{dF(x)}{dx}
\end{bmatrix}^T
$$

For the function illustrated in Figure 1,
\[
\begin{bmatrix}
1 & 1 \\
F(x)+e^{(8x+4x^2)} & \\
1 & 2 \\
x & \\
1 & \\
g(x)=[e^{(4x^4+2x^2)}] \\
2 & 1
\end{bmatrix}
\]

The gradient vector is of importance in optimization because it must be zero at an unconstrained minimum of any function with continuous first derivatives.

2.2.2. Hessian matrix

The matrix of second partial derivatives of a function is termed its Hessian matrix. The Hessian matrix of \(F(x)\) is denoted by \(G(x)\) and its \((i,j)\)th element is given by \(\frac{\partial^2 F(x)}{\partial x_i \partial x_j}\). If \(F(x)\) has continuous second derivatives, then \(G(x)\) must be positive semi-definite at any unconstrained minimum of \(F\).

2.2.3. Jacobian matrix; matrix of constraint normals

In nonlinear least-squares problems, the matrix of first partial derivatives of the vector-valued function \(f(x)\) is termed the Jacobian matrix of \(f(x)\) and its \((i,j)\)th component is \(\frac{\partial f_i}{\partial x_j}\).

The vector of first partial derivatives of the constraint \(c_i(x)\) is denoted by

\[
\begin{bmatrix}
dc_i(x) & dc_i(x) \\
i & i \\
a_i(x)=& \begin{bmatrix}
\cdots & \cdots \\
1 & n
\end{bmatrix}
\end{bmatrix}
\]

At a point, \(x\), the vector \(a_i(x)\) is orthogonal (normal) to the \(c_i(x)\) isovalue contour of \(c_i(x)\) passing through \(x\); this relationship is illustrated for a two-dimensional function in Figure 2.

Figure 2

Please see figure in printed Reference Manual
CHAPTER 22. NAG LIBRARY ROUTINES

The matrix whose columns are the vectors \( \{ a_i \} \) is termed the matrix of constraint normals. Note that if \( c(x) \) is a linear constraint involving \( a_i^T \), then its vector of first partial derivatives is simply the vector \( a_i \).

2.3. Sufficient Conditions for a Solution

All nonlinear functions will be assumed to have continuous second derivatives in the neighbourhood of the solution.

2.3.1. Unconstrained minimization

The following conditions are sufficient for the point \( x \) to be an unconstrained local minimum of \( F(x) \):

\[
\begin{align*}
(i) \quad |||g(x)||| &= 0; \text{ and} \\
(ii) \quad G(x) \text{ is positive-definite,}
\end{align*}
\]

where \( |||g||| \) denotes the Euclidean length of \( g \).

2.3.2. Minimization subject to bounds on the variables

At the solution of a bounds-constrained problem, variables which are not on their bounds are termed free variables. If it is known in advance which variables are on their bounds at the solution, the problem can be solved as an unconstrained problem in just the free variables; thus, the sufficient conditions for a solution are similar to those for the unconstrained case, applied only to the free variables.

Sufficient conditions for a feasible point \( x \) to be the solution of a bound-constrained problem are as follows:

\[
\begin{align*}
(i) \quad |||g(x)||| &= 0; \text{ and} \\
(ii) \quad G(x) \text{ is positive-definite; and}
\end{align*}
\]
where \( g(x) \) is the gradient of \( F(x) \) with respect to the free variables, and \( G(x) \) is the Hessian matrix of \( F(x) \) with respect to the free variables. The extra condition (iii) ensures that \( F(x) \) cannot be reduced by moving off one or more of the bounds.

2.3.3. Linearly-constrained minimization

For the sake of simplicity, the following description does not include a specific treatment of bounds or range constraints, since the results for general linear inequality constraints can be applied directly to these cases.

At a solution \( x^* \) of a linearly-constrained problem, the constraints which hold as equalities are called the active or binding constraints. Assume that there are \( t \) active constraints at the solution \( x^* \), and let \( A \) denote the matrix whose columns are the columns of \( A \) corresponding to the active constraints, with \( b \) the vector similarly obtained from \( b \); then

\[
A^T x^* = b. 
\]

The matrix \( Z \) is defined as an \( n \times (n-t) \) matrix satisfying:

\[
A^T Z = 0; \quad Z^T Z = I. 
\]

The columns of \( Z \) form an orthogonal basis for the set of vectors orthogonal to the columns of \( A \).

Define

\[
T \quad g(x) = Z g(x), \text{ the projected gradient vector of } F(x); \\
T \quad G(x) = Z G(x) Z, \text{ the projected Hessian matrix of } F(x). 
\]
At the solution of a linearly-constrained problem, the projected gradient vector must be zero, which implies that the gradient vector \( g(x) \) can be written as a linear combination of the columns of \( A \), i.e., \( g(x) = \sum_{i=1}^{t} \lambda_i a_i \). The scalar \( \lambda_i \) is defined as the Lagrange multiplier corresponding to the \( i \)th active constraint. A simple interpretation of the \( i \)th Lagrange multiplier is that it gives the gradient of \( F(x) \) along the \( i \)th active constraint normal; a convenient definition of the Lagrange multiplier vector (although not a recommended method for computation) is:

\[
(\lambda) = (A^TA)^{-1}A^T g(x).
\]

Sufficient conditions for \( x \) to be the solution of a linearly-constrained problem are:

(i) \( x \) is feasible, and \( A x = b \); and

(ii) \( \|g(x)\| = 0 \), or equivalently, \( g(x) = A(\lambda) \); and

(iii) \( G(x) \) is positive-definite; and

(iv) \( \lambda_i > 0 \) if \( \lambda_i \) corresponds to a constraint \( a_i^T x \geq b \); and \( \lambda_i < 0 \) if \( \lambda_i \) corresponds to a constraint \( a_i^T x \leq b \).
The sign of \((\lambda_i)\) is immaterial for equality constraints, which by definition are always active.

2.3.4. Nonlinearly-constrained minimization

For nonlinearly-constrained problems, much of the terminology is defined exactly as in the linearly-constrained case. The set of active constraints at \(x\) again means the set of constraints that hold as equalities at \(x\), with corresponding definitions of \(c\) and \(A\): the vector \(c(x)\) contains the active constraint functions, and the columns of \(A(x)\) are the gradient vectors of the active constraints. As before, \(Z\) is defined in terms of \(A(x)\) as a matrix such that:

\[
\begin{align*}
^T & A Z = 0; \quad Z Z = I
\end{align*}
\]

where the dependence on \(x\) has been suppressed for compactness.

The projected gradient vector \(g^*(x)\) is the vector \(Z^T g(x)\). At the solution \(x^*\) of a nonlinearly-constrained problem, the projected gradient must be zero, which implies the existence of Lagrange multipliers corresponding to the active constraints, i.e.,

\[
g(x^*) = A(x^*)(\lambda^*)
\]

The Lagrangian function is given by:

\[
L(x^*, (\lambda^*)) = F(x^*) - (\lambda^*) c(x^*)
\]

We define \(g_L(x)\) as the gradient of the Lagrangian function; \(G_L(x)\) as its Hessian matrix, and \(G_L^*(x)\) as its projected Hessian matrix, i.e., \(G_L^* = Z^T G_L Z\).
Sufficient conditions for $x$ to be a solution of nonlinearly-constrained problem are:

1. $x$ is feasible, and $c(x) = 0$; and
2. $||g(x)|| = 0$, or, equivalently, $g(x) = A(x)(\lambda)$; and
3. $G(x)$ is positive-definite; and
4. $(\lambda) > 0$ if $(\lambda)$ corresponds to a constraint of the form $c \geq 0$; the sign of $(\lambda)$ is immaterial for an equality constraint.

Note that condition (ii) implies that the projected gradient of the Lagrangian function must also be zero at $x$, since the application of $Z$ annihilates the matrix $A(x)$.

2.4. Background to Optimization Methods

All the algorithms contained in this Chapter generate an iterative sequence $\{x^{(k)}\}$ that converges to the solution $x$ in the limit, except for some special problem categories (i.e., linear and quadratic programming). To terminate computation of the sequence, a convergence test is performed to determine whether the current estimate of the solution is an adequate approximation. The convergence tests are discussed in Section 2.6.

Most of the methods construct a sequence $\{x^{(k)}\}$ satisfying:

$$x^{(k+1)} = x^{(k)} + (\alpha) p^{(k)}$$

where the vector $p^{(k)}$ is termed the direction of search, and $(\alpha)^{(k)}$ is the steplength. The steplength $(\alpha)^{(k)}$ is chosen so that $F(x^{(k+1)}) < F(x^{(k)})$. 
2.4.1. Methods for unconstrained optimization

The distinctions among methods arise primarily from the need to use varying levels of information about derivatives of \( F(x) \) in defining the search direction. We describe three basic approaches to unconstrained problems, which may be extended to other problem categories. Since a full description of the methods would fill several volumes, the discussion here can do little more than allude to the processes involved, and direct the reader to other sources for a full explanation.

(a) Newton-type Methods (Modified Newton Methods)

Newton-type methods use the Hessian matrix \( G(x) \), or a finite difference approximation to \( G(x) \), to define the search direction. The routines in the Library either require a subroutine that computes the elements of \( G(x) \), or they approximate \( G(x) \) by finite differences.

Newton-type methods are the most powerful methods available for general problems and will find the minimum of a quadratic function in one iteration. See Sections 4.4. and 4.5.1. of Gill et al [5].

(b) Quasi-Newton Methods

Quasi-Newton methods approximate the Hessian \( G(x) \) by a matrix \( B \) which is modified at each iteration to include information obtained about the curvature of \( F \) along the latest search direction. Although not as robust as Newton-type methods, quasi-Newton methods can be more efficient because \( G(x) \) is not computed, or approximated by finite-differences. Quasi-Newton methods minimize a quadratic function in \( n \) iterations. See Section 4.5.2 of Gill et al [5].

(c) Conjugate-Gradient Methods

Unlike Newton-type and quasi-Newton methods, conjugate gradient methods do not require the storage of an \( n \) by \( n \) matrix and so are ideally suited to solve large problems.
Conjugate-gradient type methods are not usually as reliable or efficient as Newton-type, or quasi-Newton methods. See Section 4.8.3 of Gill et al [5].

2.4.2. Methods for nonlinear least-squares problems

These methods are similar to those for unconstrained optimization, but exploit the special structure of the Hessian matrix to give improved computational efficiency.

Since

\[ F(x) = \sum_{i=1}^{m} f(x_i) \]

the Hessian matrix \( G(x) \) is of the form

\[ G(x) = 2 \sum_{i=1}^{m} J(x) J(x)^T f(x_i) G(x_i), \]

where \( J(x) \) is the Jacobian matrix of \( f(x) \), and \( G(x_i) \) is the Hessian matrix of \( f(x_i) \).

In the neighbourhood of the solution, \( ||f(x)|| \) is often small compared to \( ||J(x) J(x)^T|| \) (for example, when \( f(x) \) represents the goodness of fit of a nonlinear model to observed data). In such cases, \( 2J(x) J(x)^T \) may be an adequate approximation to \( G(x) \), thereby avoiding the need to compute or approximate second derivatives of \( f(x) \). See Section 4.7 of Gill et al [5].

2.4.3. Methods for handling constraints

Bounds on the variables are dealt with by fixing some of the variables on their bounds and adjusting the remaining free variables to minimize the function. By examining estimates of the Lagrange multipliers it is possible to adjust the set of variables fixed on their bounds so that eventually the bounds active at the solution should be correctly identified. This type
of method is called an active set method. One feature of such methods is that, given an initial feasible point, all \((k)\) approximations \(x^{(k)}\) are feasible. This approach can be extended to general linear constraints. At a point, \(x\), the set of constraints which hold as equalities being used to predict, or approximate, the set of active constraints is called the working set.

Nonlinear constraints are more difficult to handle. If at all possible, it is usually beneficial to avoid including nonlinear constraints during the formulation of the problem. The methods currently implemented in the Library handle nonlinearly constrained problems either by transforming them into a sequence of bound constraint problems, or by transforming them into a sequence of quadratic programming problems. A feature of almost all methods for nonlinear constraints is that \(x^{(k)}\) is not guaranteed to be feasible except in the limit, and this is certainly true of the routines currently in the Library. See Chapter 6, particularly Section 6.4 and Section 6.5 of Gill et al [5].

Anyone interested in a detailed description of methods for optimization should consult the references.

2.5. Scaling

Scaling (in a broadly defined sense) often has a significant influence on the performance of optimization methods. Since convergence tolerances and other criteria are necessarily based on an implicit definition of 'small' and 'large', problems with unusual or unbalanced scaling may cause difficulties for some algorithms. Nonetheless, there are currently no scaling routines in the Library, although the position is under constant review. In light of the present state of the art, it is considered that sensible scaling by the user is likely to be more effective than any automatic routine. The following sections present some general comments on problem scaling.

2.5.1. Transformation of variables

One method of scaling is to transform the variables from their original representation, which may reflect the physical nature of the problem, to variables that have certain desirable properties in terms of optimization. It is generally helpful for the following conditions to be satisfied:

(i) the variables are all of similar magnitude in the region of interest;
(ii) a fixed change in any of the variables results in similar changes in $F(x)$. Ideally, a unit change in any variable produces a unit change in $F(x)$;

(iii) the variables are transformed so as to avoid cancellation error in the evaluation of $F(x)$.

Normally, users should restrict themselves to linear transformations of variables, although occasionally nonlinear transformations are possible. The most common such transformation (and often the most appropriate) is of the form

$$x = Dx,$$

where $D$ is a diagonal matrix with constant coefficients. Our experience suggests that more use should be made of the transformation

$$x = Dx + v,$$

where $v$ is a constant vector.

Consider, for example, a problem in which the variable $x$ represents the position of the peak of a Gaussian curve to be fitted to data for which the extreme values are 150 and 170; therefore $x$ is known to lie in the range 150--170. One possible scaling would be to define a new variable $x'$, given by

$$x' = \frac{3}{3} x,$$

$$x = \frac{3}{170}.$$

A better transformation, however, is given by defining $x$ as

$$x = -160.$$
Frequently, an improvement in the accuracy of evaluation of \( F(x) \) can result if the variables are scaled before the routines to evaluate \( F(x) \) are coded. For instance, in the above problem just mentioned of Gaussian curve fitting, \( x \) may always occur in terms of the form \( (x - x_m) \), where \( x_m \) is a constant representing the mean peak position.

2.5.2. Scaling the objective function

The objective function has already been mentioned in the discussion of scaling the variables. The solution of a given problem is unaltered if \( F(x) \) is multiplied by a positive constant, or if a constant value is added to \( F(x) \). It is generally preferable for the objective function to be of the order of unity in the region of interest; thus, if in the original formulation \( F(x) \) is always of the order of \( 10^{-5} \) (say), then the value of \( F(x) \) should be multiplied by 10 when evaluating the function within the optimization routines. If a constant is added or subtracted in the computation of \( F(x) \), usually it should be omitted - i.e., it is better to formulate \( F(x) \) as \( x_1^2 + x_2^2 \) rather than as \( x_1^2 + x_2^2 + 1000 \) or even \( x_1 + x_2 + 1 \). The inclusion of such a constant in the calculation of \( F(x) \) can result in a loss of significant figures.

2.5.3. Scaling the constraints

The solution of a nonlinearly-constrained problem is unaltered if the \( i \)th constraint is multiplied by a positive weight \( w_i \). At the approximation of the solution determined by a Library routine, the active constraints will not be satisfied exactly, but will have 'small' values (for example, \( c_1 = 10^{-6} \), \( c_2 = 10^{-8} \), etc.). In general, this discrepancy will be minimized if the constraints are weighted so that a unit change in \( x \) produces a similar change in each constraint.

A second reason for introducing weights is related to the effect of the size of the constraints on the Lagrange multiplier estimates and, consequently, on the active set strategy. Additional discussion is given in Gill et al [5].
2.6. Analysis of Computed Results

2.6.1. Convergence criteria

The convergence criteria inevitably vary from routine to routine, since in some cases more information is available to be checked (for example, is the Hessian matrix positive-definite?), and different checks need to be made for different problem categories (for example, in constrained minimization it is necessary to verify whether a trial solution is feasible). Nonetheless, the underlying principles of the various criteria are the same; in non-mathematical terms, they are:

\begin{align*}
(i) & \quad \text{is the sequence } \{x_k\} \text{ converging?} \\
(ii) & \quad \text{is the sequence } \{F_k\} \text{ converging?} \\
(iii) & \quad \text{are the necessary and sufficient conditions for the solution satisfied?}
\end{align*}

The decision as to whether a sequence is converging is necessarily speculative. The criterion used in the present routines is to assume convergence if the relative change occurring between two successive iterations is less than some prescribed quantity. Criterion (iii) is the most reliable but often the conditions cannot be checked fully because not all the required information may be available.

2.6.2. Checking results

Little a priori guidance can be given as to the quality of the solution found by a nonlinear optimization algorithm, since no guarantees can be given that the methods will always work. Therefore, it is necessary for the user to check the computed solution even if the routine reports success. Frequently a 'solution' may have been found even when the routine does not report a success. The reason for this apparent contradiction is that the routine needs to assess the accuracy of the solution. This assessment is not an exact process and consequently may be unduly pessimistic. Any 'solution' is in general only an approximation to the exact solution, and it is possible that the accuracy specified by the user is too stringent.

Further confirmation can be sought by trying to check whether or not convergence tests are almost satisfied, or whether or not some of the sufficient conditions are nearly satisfied. When it is thought that a routine has returned a non-zero value of IFAIL
only because the requirements for 'success' were too stringent it may be worth restarting with increased convergence tolerances.

For nonlinearily-constrained problems, check whether the solution returned is feasible, or nearly feasible; if not, the solution returned is not an adequate solution.

Confidence in a solution may be increased by resolving the problem with a different initial approximation to the solution. See Section 8.3 of Gill et al [5] for further information.

2.6.3. Monitoring progress

Many of the routines in the Chapter have facilities to allow the user to monitor the progress of the minimization process, and users are encouraged to make use of these facilities. Monitoring information can be a great aid in assessing whether or not a satisfactory solution has been obtained, and in indicating difficulties in the minimization problem or in the routine’s ability to cope with the problem.

The behaviour of the function, the estimated solution and first derivatives can help in deciding whether a solution is acceptable and what to do in the event of a return with a non-zero value of IFAIL.

2.6.4. Confidence intervals for least-squares solutions

When estimates of the parameters in a nonlinear least-squares problem have been found, it may be necessary to estimate the variances of the parameters and the fitted function. These can be calculated from the Hessian of \( F(x) \) at the solution.

In many least-squares problems, the Hessian is adequately approximated at the solution by \( G=2J J \) (see Section 2.4.3). The Jacobian, \( J \), or a factorization of \( J \) is returned by all the comprehensive least-squares routines and, in addition, a routine is supplied in the Library to estimate variances of the parameters following the use of most of the nonlinear least-squares routines, in the case that \( G=2J J \) is an adequate approximation.

Let \( H \) be the inverse of \( G \), and \( S \) be the sum of squares, both calculated at the solution \( x \); an unbiased estimate of the variance of the \( i \)th parameter \( x_i \) is
and an unbiased estimate of the covariance of $x_i$ and $x_j$ is
\[ \text{covar}(x_i, x_j) = -\frac{\text{var}(x)}{m-n} \]

*If $x$ is the true solution, then the $100(1-(\beta))$ confidence interval on $x$ is
\[
\frac{x_i - \sqrt{\text{var}(x_i)t}}{t} < x_i < \frac{x_i + \sqrt{\text{var}(x_i)t}}{t}, \quad i = 1, 2, \ldots, n
\]

where $t$ is the $100(1-(\beta))/2$ percentage point of the $t$-distribution with $m-n$ degrees of freedom.

In the majority of problems, the residuals $f_i$, for $i = 1, 2, \ldots, m$, contain the difference between the values of a model function $(\phi)(z, x)$ calculated for $m$ different values of the independent variable $z$, and the corresponding observed values at these points. The minimization process determines the parameters, or constants $x$, of the fitted function $(\phi)(z, x)$. For any value, $z$, of the independent variable $z$, an unbiased estimate of the variance of $(\phi)$ is
\[
\text{var}(\phi) = \frac{n}{n-1} \text{var}(\phi)
\]
The $100(1-(\beta))$ confidence interval on $F$ at the point $z$ is

\[
(\phi)(z,x) - \sqrt{\text{var}(\phi)} t_{((\beta)/2,m-n)} < (\phi)(z,x) + \sqrt{\text{var}(\phi)} t_{((\beta)/2,m-n)}
\]

For further details on the analysis of least-squares solutions see Bard [1] and Wolberg [7].

2.7. References

3. Recommendations on Choice and Use of Routines

The choice of routine depends on several factors: the type of problem (unconstrained, etc.); the level of derivative information available (function values only, etc.); the experience of the user (there are easy-to-use versions of some routines); whether or not storage is a problem; and whether
computational time has a high priority.

3.1. Choice of Routine

Routines are provided to solve the following types of problem:

- Nonlinear Programming: E04UCF
- Quadratic Programming: E04NAF
- Linear Programming: E04MBF
- Nonlinear Function: E04DGF
  (using 1st derivatives)
- Nonlinear Function, unconstrained or simple bounds: E04JAF
  (using function values only)
- Nonlinear least-squares: E04PDF
  (using function values only)
- Nonlinear least-squares: E04GCF
  (using function values and 1st derivatives)

E04UCF can be used to solve unconstrained, bound-constrained and linearly-constrained problems.

E04NAF can be used as a comprehensive linear programming solver; however, in most cases the easy-to-use routine E04MBF will be adequate.

E04MBF can be used to obtain a feasible point for a set of linear constraints.

E04DGF can be used to solve large scale unconstrained problems.

The routines can be used to solve problems in a single variable.

3.2. Service Routines

One of the most common errors in use of optimization routines is that the user's subroutines incorrectly evaluate the relevant partial derivatives. Because exact gradient information normally enhances efficiency in all areas of optimization, the user should be encouraged to provide analytical derivatives whenever possible. However, mistakes in the computation of derivatives can result in serious and obscure run-time errors, as well as complaints that the Library routines are incorrect.

E04UCF incorporates a check on the gradients being supplied and users are encouraged to utilize this option; E04GCF also incorporates a call to a derivative checker.

E04YCF estimates selected elements of the variance-covariance matrix for the computed regression parameters following the use
of a nonlinear least-squares routine.

3.3. Function Evaluations at Infeasible Points

Users must not assume that the routines for constrained problems will require the objective function to be evaluated only at points which satisfy the constraints, i.e., feasible points. In the first place some of the easy-to-use routines call a service routine which will evaluate the objective function at the user-supplied initial point, and at neighbouring points (to check user-supplied derivatives or to estimate intervals for finite differencing). Apart from this, all routines will ensure that any evaluations of the objective function occur at points which approximately satisfy any simple bounds or linear constraints. Satisfaction of such constraints is only approximate because:

(a) routines which have a parameter FEATOL may allow such constraints to be violated by a margin specified by FEATOL;

(b) routines which estimate derivatives by finite differences may require function evaluations at points which just violate such constraints even though the current iteration just satisfies them.

There is no attempt to ensure that the current iteration satisfies any nonlinear constraints. Users who wish to prevent their objective function being evaluated outside some known region (where it may be undefined or not practically computable), may try to confine the iteration within this region by imposing suitable simple bounds or linear constraints (but beware as this may create new local minima where these constraints are active).

Note also that some routines allow the user-supplied routine to return a parameter (MODE) with a negative value to force an immediate clean exit from the minimization when the objective function cannot be evaluated.

3.4. Related Problems

Apart from the standard types of optimization problem, there are other related problems which can be solved by routines in this or other chapters of the Library.

E04MBF can be used to find a feasible point for a set of linear constraints and simple bounds.

Two routines in Chapter E04 solve linear least-squares problems,

\[ \minimize \quad \sum_{i=1}^{m} \sum_{j=1}^{n} \quad 2 \]

i.e., minimize \( \sum_{i=1}^{m} \sum_{j=1}^{n} \) where \( \sum_{i=1}^{m} \sum_{j=1}^{n} \)
E02GAF solves an overdetermined system of linear equations in the \( m \) norm, i.e., minimizes \( \sum_{i=1}^{\infty} |r(x)| \), with \( r \) as above.

EO4 -- Minimizing or Maximizing a Function
EO4DGFS -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

Note for users via the Axiom system: the interface to this routine has been enhanced for use with Axiom and is slightly different to that offered in the standard version of the Foundation Library. In particular, the optional parameters of the NAG routine are now included in the parameter list. These are described in section 5.1.2, below.

1. Purpose

EO4DGFS minimizes an unconstrained nonlinear function of several variables using a pre-conditioned, limited memory quasi-Newton conjugate gradient method. First derivatives are required. The routine is intended for use on large scale problems.

2. Specification

SUBROUTINE EO4DGFS(N,OBJFUN,ITER,OBJF,OBJGRD,X,IWORK,WORK,IUSER,
3. Description

E04DGF uses a pre-conditioned conjugate gradient method and is based upon algorithm PLMA as described in Gill and Murray [1] and Gill et al [2] Section 4.8.3.

The algorithm proceeds as follows:

Let $x$ be a given starting point and let $k$ denote the current iteration, starting with $k=0$. The iteration requires $g_k$, the gradient vector evaluated at $x_k$, the $k$th estimate of the minimum.

At each iteration a vector $p_k$ (known as the direction of search) is computed and the new estimate $x_{k+1}$ is given by $x_k + (\alpha_k) p_k$ where $(\alpha_k)$ (the step length) minimizes the function $F(x_k + (\alpha_k) p_k)$ with respect to the scalar $(\alpha_k)$. A choice of initial step $(\alpha_0)$ is taken as

$$
(\alpha_0) = \min\{1, 2|F - F_{est}|/g_{k est} g_k\}
$$

where $F$ is a user-supplied estimate of the function value at the solution. If $F$ is not specified, the software always chooses the unit step length for $(\alpha_k)$. Subsequent step length estimates are computed using cubic interpolation with safeguards.

A quasi-Newton method can be used to compute the search direction $p_k$ by updating the inverse of the approximate Hessian ($H_k$) and computing
The updating formula for the approximate inverse is given by

\[
p_{k+1} = -H_{k+1} g_{k+1}
\]

The method used by E04DGF to obtain the search direction is based upon computing \( p \) as \(-H \cdot g \) where \( H \) is a matrix obtained by updating the identity matrix with a limited number of quasi-Newton corrections. The storage of an \( n \) by \( n \) matrix is avoided by storing only the vectors that define the rank two corrections - hence the term limited-memory quasi-Newton method. The precise method depends upon the number of updating vectors stored. For example, the direction obtained with the 'one-step' limited memory update is given by (1) using (2) with \( H \) equal to the identity matrix, viz.

\[
p_{k+1} = -g_{k+1} + \left( \sum_{k} y_{k} \cdot s_{k} \right) - \left( \sum_{k} s_{k} \cdot y_{k} \right)
\]

E04DGF uses a two-step method described in detail in Gill and Murray [1] in which restarts and pre-conditioning are incorporated. Using a limited-memory quasi-Newton formula, such as the one above, guarantees \( p \) to be a descent direction if all the inner products \( y \) are positive for all vectors \( y \) and \( s \) used in the updating formula.

The termination criterion of E04DGF is as follows:

Let (\( \text{tau} \)) specify a parameter that indicates the number of
correct figures desired in $F$ ($(\tau)$ is equivalent to Optimality Tolerance in the optional parameter list, see Section 5.1). If the following three conditions are satisfied

(i) $F_{k-1} - F_k < (\tau) (1 + |F_k|)$

(ii) $\|x_{k-1} - x_k\| < (\tau) (1 + \|x_k\|)$

(iii) $\|g_k\| \leq 3(\tau) (1 + |F_k|)$ or $\|g_k\| < (\epsilon)$, where $(\epsilon)$ is the absolute error associated with $A$

then the algorithm is considered to have converged. For a full discussion on termination criteria see Gill et al [2] Chapter 8.

4. References

5. Parameters

1: $N$ -- INTEGER Input
   On entry: the number $n$ of variables. Constraint: $N \geq 1$.

2: OBJFUN -- SUBROUTINE, supplied by the user.
   External Procedure
   OBJFUN must calculate the objective function $F(x)$ and its gradient for a specified $n$ element vector $x$.

   Its specification is:

   SUBROUTINE OBJFUN (MODE, N, X, OBJF, OBJGRD, 1
   INTEGER NSTATE, IUSER, USER)
   DOUBLE PRECISION X(N), OBJF, OBJGRD(N), USER(*)

   1: MODE -- INTEGER Input/Output
MODE is a flag that the user may set within OBJFUN to indicate a failure in the evaluation of the objective function. On entry: MODE is always non-negative. On exit: if MODE is negative the execution of E04DGF is terminated with IFAIL set to MODE.

2: N -- INTEGER Input
   On entry: the number n of variables.

3: X(N) -- DOUBLE PRECISION array Input
   On entry: the point x at which the objective function is required.

4: OBJF -- DOUBLE PRECISION Output
   On exit: the value of the objective function F at the current point x.

5: OBJGRD(N) -- DOUBLE PRECISION array Output
   On exit: OBJGRD(i) must contain the value of \( \frac{ddF}{ddx} \) at the point x, for i=1,2,...,n.

6: NSTATE -- INTEGER Input
   On entry: NSTATE will be 1 on the first call of OBJFUN by E04DGF, and is 0 for all subsequent calls. Thus, if the user wishes, NSTATE may be tested within OBJFUN in order to perform certain calculations once only. For example the user may read data or initialise COMMON blocks when NSTATE = 1.

7: IUSER(*) -- INTEGER array User Workspace

8: USER(*) -- DOUBLE PRECISION array User Workspace
   OBJFUN is called from E04DGF with the parameters IUSER and USER as supplied to E04DGF. The user is free to use arrays IUSER and USER to supply information to OBJFUN as an alternative to using COMMON.

OBJFUN must be declared as EXTERNAL in the (sub)program from which E04DGF is called. Parameters denoted as Input must not be changed by this procedure.

3: ITER -- INTEGER Output
   On exit: the number of iterations performed.

4: OBJF -- DOUBLE PRECISION Output
   On exit: the value of the objective function F(x) at the final iterate.
5: OBJGRD(N) -- DOUBLE PRECISION array Output
On exit: the objective gradient at the final iterate.

6: X(N) -- DOUBLE PRECISION array Input/Output
On entry: an initial estimate of the solution. On exit: the final estimate of the solution.

7: IWORK(N+1) -- INTEGER array Workspace

8: WORK(13*N) -- DOUBLE PRECISION array Workspace

9: IUSER(*) -- INTEGER array User Workspace
Note: the dimension of the array IUSER must be at least 1.
This array is not used by E04DGF, but is passed directly to routine OBJFUN and may be used to supply information to OBJFUN.

10: USER(*) -- DOUBLE PRECISION array User Workspace
Note: the dimension of the array USER must be at least 1.
This array is not used by E04DGF, but is passed directly to routine OBJFUN and may be used to supply information to OBJFUN.

11: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. Users who are unfamiliar with this parameter should refer to the Essential Introduction for details.
On exit: IFAIL = 0 unless the routine detects an error or gives a warning (see Section 6).
For this routine, because the values of output parameters may be useful even if IFAIL /=0 on exit, users are recommended to set IFAIL to -1 before entry. It is then essential to test the value of IFAIL on exit.

5.1. Optional Input Parameters

Several optional parameters in E04DGF define choices in the behaviour of the routine. In order to reduce the number of formal parameters of E04DGF these optional parameters have associated default values (see Section 5.1.3) that are appropriate for most problems. Therefore the user need only specify those optional parameters whose values are to be different from their default values.

The remainder of this section can be skipped by users who wish to use the default values for all optional parameters. A complete list of optional parameters and their default values is given in
Section 5.1.3.

5.1.1. Specification of the Optional Parameters

Optional parameters may be specified by calling one, or both, of E04DJF and E04DKF prior to a call to E04DGF.

E04DJF reads options from an external options file, with Begin and End as the first and last lines respectively and each intermediate line defining a single optional parameter. For example,

```
Begin
Print Level = 1
End
```

The call

```
CALL E04DJF(IOPTNS, INFORM)
```

can then be used to read the file on unit IOPTNS. INFORM will be zero on successful exit. E04DJF should be consulted for a full description of this method of supplying optional parameters.

E04DKF can be called to supply options directly, one call being necessary for each optional parameter.

For example,

```
CALL E04DKF(‘Print level = 1’)
```

E04DKF should be consulted for a full description of this method of supplying optional parameters.

All optional parameters not specified by the user are set to their default values. Optional parameters specified by the user are unaltered by E04DGF (unless they define invalid values) and so remain in effect for subsequent calls to E04DGF, unless altered by the user.

5.1.2. Description of the Optional Parameters

The following list (in alphabetical order) gives the valid options. For each option, we give the keyword, any essential optional qualifiers, the default value, and the definition. The minimum valid abbreviation of each keyword is underlined. If no characters of an optional qualifier are underlined, the qualifier may be omitted. The letter a denotes a phrase (character string)
that qualifies an option. The letters i and r denote INTEGER and real values required with certain options. The number (epsilon) is a generic notation for machine precision, and (epsilon) 
\[ R \]
denotes the relative precision of the objective function (the optional parameter Function Precision; see below).

Defaults

This special keyword may be used to reset the default values following a call to E04DGF.

Estimated Optimal Function Value r

(Axiom parameter ES)

This value of r specifies the user-supplied guess of the optimum objective function value. This value is used by E04DGF to calculate an initial step length (see Section 3). If the value of r is not specified by the user (the default), then this has the effect of setting the initial step length to unity. It should be noted that for badly scaled functions a unit step along the steepest descent direction will often compute the function at very large values of x.

0.9

Function Precision r Default = (epsilon)

(Axiom parameter FU)

The parameter defines (epsilon), which is intended to be a 
\[ R \]
measure of the accuracy with which the problem function F can be computed. The value of (epsilon) should reflect the relative 
\[ R \]
precision of 1+|F(x)|; i.e. (epsilon) acts as a relative 
\[ R \]
precision when |F| is large, and as an absolute precision when |F| is small. For example, if F(x) is typically of order 1000 and the first six significant digits are known to be correct, an appropriate value for (epsilon) would be 1.0E-6. In contrast, if \[ R \]
-4
F(x) is typically of order 10 and the first six significant digits are known to be correct, an appropriate value for (epsilon) would be 1.0E-10. The choice of (epsilon) can be 
\[ R \]
quite complicated for badly scaled problems; see Chapter 8 of Gill and Murray [2], for a discussion of scaling techniques. The default value is appropriate for most simple functions that are
computed with full accuracy. However when the accuracy of the computed function values is known to be significantly worse than full precision, the value of (epsilon) should be large enough so that E04DGF will not attempt to distinguish between function values that differ by less than the error inherent in the calculation. If 0 <= r < (epsilon), where (epsilon) is the machine precision then the default value is used.

Iteration Limit  i Default = \text{max}(50, 5n)

Iters

Itns

(Axiom parameter IT)

The value i (i \geq 0) specifies the maximum number of iterations allowed before termination. If i < 0 the default value is used. See Section 8 for further information.

Linesearch Tolerance  r Default = 0.9

(Axiom parameter LIN)

The value r (0 \leq r < 1) controls the accuracy with which the step (alpha) taken during each iteration approximates a minimum of the function along the search direction (the smaller the value of r, the more accurate the linesearch). The default value r = 0.9 requests an inaccurate search, and is appropriate for most problems. A more accurate search may be appropriate when it is desirable to reduce the number of iterations - for example, if the objective function is cheap to evaluate.

List  Default = List

Nolist

(Axiom parameter LIST)

Normally each optional parameter specification is printed as it is supplied. Nolist may be used to suppress the printing and List may be used to restore printing.

Maximum Step Length  r Default = 10

(Axiom parameter MA)

The value r (r > 0) defines the maximum allowable step length for the line search. If r \leq 0 the default value is used.
Optimality Tolerance  $r$ Default = $(\varepsilon)$

(Axiom parameter OP)

The parameter $r$ ($(\varepsilon) \leq r < 1$) specifies the accuracy to which

the user wishes the final iterate to approximate a solution of

the problem. Broadly speaking, $r$ indicates the number of correct

figures desired in the objective function at the solution. For

example, if $r$ is 10 and E04DGF terminates successfully, the

final value of $F$ should have approximately six correct figures.

E04DGF will terminate successfully if the iterative sequence of $x$

-values is judged to have converged and the final point satisfies

the termination criteria (see Section 3, where $(\tau)$ represents

$F$ Optimality Tolerance).

Print Level  $i$ Default = 10

(Axiom parameter PR)

The value $i$ controls the amount of printout produced by E04DGF.
The following levels of printing are available.

$i$  Output.

0  No output.

1  The final solution.

5  One line of output for each iteration.

10  The final solution and one line of output for each iteration.

Start Objective Check at Variable  $i$ Default = 1

(Axiom parameter STA)

Stop Objective Check at Variable  $i$ Default = $n$

(Axiom parameter STD)

These keywords take effect only if Verify Level > 0 (see below).
They may be used to control the verification of gradient elements
computed by subroutine OBJFUN. For example if the first 30
variables appear linearly in the objective, so that the
corresponding gradient elements are constant, then it is reasonable to specify Start Objective Check at Variable 31.

Verify Level i Default = 0
Verify No
Verify Level -1
Verify Level 0
Verify
Verify Yes
Verify Objective Gradients
Verify Gradients
Verify Level 1

(Axiom parameter VE)

These keywords refer to finite-difference checks on the gradient elements computed by the user-provided subroutine OBJFUN. It is possible to set Verify Level in several ways, as indicated above. For example, the gradients will be verified if Verify, Verify Yes, Verify Gradients, Verify Objective Gradients or Verify Level = 1 is specified.

If i<0 then no checking will be performed. If i>0 then the gradients will be verified at the user-supplied point. If i=0 only a ‘cheap’ test will be performed, requiring one call to OBJFUN. If i=1, a more reliable (but more expensive) check will be made on individual gradient components, within the ranges specified by the Start and Stop keywords as described above. A result of the form OK or BAD? is printed by E04DGF to indicate whether or not each component appears to be correct.

5.1.3. Optional parameter checklist and default values

For easy reference, the following sample list shows all valid keywords and their default values. The default options Function Precision and Optimality Tolerance depend upon (epsilon), the machine precision.

Optional Parameters Default Values

Estimated Optimal Function Value
Function precision (epsilon)
Iterations \( \max(50, 5n) \)
Linesearch Tolerance 0.9
Maximum Step Length 10
List/Nolist List

Optimality Tolerance (epsilon)
Print Level 10
Start Objective Check at 1 Variable
Stop Objective Check at \( n \) Variable
Verify Level 0

5.2. Description of Printed Output

The level of printed output from E04DGF is controlled by the user (see the description of Print Level in Section 5.1).

When Print Level \( \geq 5 \), the following line of output is produced at each iteration.

\( \text{Itn} \) is the iteration count.

\( \text{Step} \) is the step (alpha) taken along the computed search direction. On reasonably well-behaved problems, the unit step will be taken as the solution is approached.

\( \text{Nfun} \) is the cumulated number of evaluations of the objective function needed for the linesearch. Evaluations needed for the estimation of the gradients by finite differences are not included. \( \text{Nfun} \) is printed as a guide to the amount of work required for the linesearch. E04DGF will perform at most 16 function evaluations per iteration.

\( \text{Objective} \) is the value of the objective function.
Norm $G$ is the Euclidean norm of the gradient of the objective function.

Norm $X$ is the Euclidean norm of $x$.

Norm $(X^{(k-1)} - X^{(k)})$ is the Euclidean norm of $x^{(k-1)} - x^{(k)}$.

When Print Level $= 1$ or Print Level $\geq 10$ then the solution at the end of execution of E04DGF is printed out.

The following describes the printout for each variable:

- **Variable** gives the name (VARBL) and index $j$ ($j = 1$ to $n$) of the variable
- **Value** is the value of the variable at the final iterate
- **Gradient Value** is the value of the gradient of the objective function with respect to the $j$th variable at the final iterate

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

If on entry IFAIL $= 0$ or $-1$, explanatory error messages are output on the current error message unit (as defined by X04AAF).

On exit from E04DGF, IFAIL should be tested. If Print Level $> 0$ then a short description of IFAIL is printed.

Errors and diagnostics indicated by IFAIL from E04DGF are as follows:

- **IFAIL** $< 0$
  - A negative value of IFAIL indicates an exit from E04DGF because the user set MODE negative in routine OBJFUN. The value of IFAIL will be the same as the user's setting of MODE.

- **IFAIL** $= 1$
  - Not used by this routine.

- **IFAIL** $= 2$
  - Not used by this routine.

- **IFAIL** $= 3$
  - The maximum number of iterations has been performed. If the
algorithm appears to be making progress the iterations value may be too small (see Section 5.1.2) so the user should increase iterations and rerun E04DGF. If the algorithm seems to be 'bogged down', the user should check for incorrect gradients or ill-conditioning as described below under IFAIL = 6.

IFAIL = 4
The computed upper bound on the step length taken during the linesearch was too small. A rerun with an increased value of the Maximum Step Length ((rho) say) may be successful unless

\[ (\rho) > 10 \quad \text{the default value}, \]

in which case the current point cannot be improved upon.

IFAIL = 5
Not used by this routine.

IFAIL = 6
A sufficient decrease in the function value could not be attained during the final linesearch. If the subroutine OBJFUN computes the function and gradients correctly, then this may occur because an overly stringent accuracy has been requested, i.e., Optimality Tolerance is too small or if the minimum lies close to a step length of zero. In this case the user should apply the four tests described in Section 3 to determine whether or not the final solution is acceptable (the user will need to set Print Level \( \geq 5 \)). For a discussion of attainable accuracy see Gill and Murray [2].

If many iterations have occurred in which essentially no progress has been made or E04DGF has failed to move from the initial point, subroutine OBJFUN may be incorrect. The user should refer to the comments below under IFAIL = 7 and check the gradients using the Verify parameter. Unfortunately, there may be small errors in the objective gradients that cannot be detected by the verification process. Finite-difference approximations to first derivatives are catastrophically affected by even small inaccuracies.

IFAIL = 7
Large errors were found in the derivatives of the objective function. This value of IFAIL will occur if the verification process indicated that at least one gradient component had no correct figures. The user should refer to the printed output to determine which elements are suspected to be in error.

As a first step, the user should check that the code for the objective values is correct - for example, by computing the
function at a point where the correct value is known. However, care should be taken that the chosen point fully tests the evaluation of the function. It is remarkable how often the values $x=0$ or $x=1$ are used to test function evaluation procedures, and how often the special properties of these numbers make the test meaningless.

Special care should be used in this test if computation of the objective function involves subsidiary data communicated in COMMON storage. Although the first evaluation of the function may be correct, subsequent calculations may be in error because some of the subsidiary data has accidentally been overwritten.

Errors in programming the function may be quite subtle in that the function value is 'almost' correct. For example, the function may not be accurate to full precision because of the inaccurate calculation of a subsidiary quantity, or the limited accuracy of data upon which the function depends. A common error on machines where numerical calculations are usually performed in double precision is to include even one single-precision constant in the calculation of the function; since some compilers do not convert such constants to double precision, half the correct figures may be lost by such a seemingly trivial error.

**IFAIL = 8**
The gradient ($g$) at the starting point is too small. The $T$ value $g g$ is less than $(\epsilon)$ $|F(x)|$, where $(\epsilon)$ is the machine precision.

The problem should be rerun at a different starting point.

**IFAIL = 9**
On entry $N < 1$.

7. Accuracy

On successful exit the accuracy of the solution will be as defined by the optional parameter Optimality Tolerance.

8. Further Comments

Problems whose Hessian matrices at the solution contain sets of clustered eigenvalues are likely to be minimized in significantly fewer than $n$ iterations. Problems without this property may require anything between $n$ and $5n$ iterations, with approximately $2n$ iterations being a common figure for moderately difficult
3362  CHAPTER 22.  NAG LIBRARY ROUTINES

problems.

9. Example

To find a minimum of the function

\[
F(x) = e^{(4x_1 + 2x_2 + 4x_1 x_2 + 2x_2 + 1)}.
\]

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

Supply optional parameters to E04DGF from file

--- nage.ht ---

\begin{verbatim}
E04DJF(3NAG)  Foundation Library (12/10/92)  E04DJF(3NAG)

E04 -- Minimizing or Maximizing a Function  E04DJF
E04DJF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

To supply optional parameters to E04DGF from an external file.

2. Specification
SUBROUTINE E04DJF (IOPTNS, INFORM)
INTEGER IOPTNS, INFORM

3. Description

E04DJF may be used to supply values for optional parameters to
E04DGF. E04DJF reads an external file and each line of the file
defines a single optional parameter. It is only necessary to
supply values for those parameters whose values are to be
different from their default values.

Each optional parameter is defined by a single character string
of up to 72 characters, consisting of one or more items. The
items associated with a given option must be separated by spaces,
or equal signs (=). Alphabetic characters may be upper or lower
case. The string

\text{Print level = 1}

is an example of a string used to set an optional parameter. For
each option the string contains one or more of the following
items:

(a) A mandatory keyword.

(b) A phrase that qualifies the keyword.

(c) A number that specifies an INTEGER or real value. Such
numbers may be up to 16 contiguous characters in Fortran
77's I, F, E or D formats, terminated by a space if this is
not the last item on the line.

Blank strings and comments are ignored. A comment begins with an
asterisk (*) and all subsequent characters in the string are
regarded as part of the comment.

The file containing the options must start with begin and must
finish with end. An example of a valid options file is:

\text{Begin * Example options file}
  \text{Print level = 10}
\text{End}

Normally each line of the file is printed as it is read, on the
current advisory message unit (see X04ABF), but printing may be
suppressed using the keyword nolist. To suppress printing of
begin, nolist must be the first option supplied as in the file:
Begin
Nolist
Print level = 10
End

Printing will automatically be turned on again after a call to E04DGF and may be turned on again at any time by the user by using the keyword list.

Optional parameter settings are preserved following a call to E04DGF, and so the keyword defaults is provided to allow the user to reset all the optional parameters to their default values prior to a subsequent call to E04DGF.

A complete list of optional parameters, their abbreviations, synonyms and default values is given in Section 5.1 of the routine document for E04DGF.

4. References
None.

5. Parameters

1: IOPTNS -- INTEGER Input
   On entry: IOPTNS must be the unit number of the options file. Constraint: 0 <= IOPTNS <= 99.

2: INFORM -- INTEGER Output
   On exit: INFORM will be zero if an options file with the correct structure has been read. Otherwise INFORM will be positive. Positive values of INFORM indicate that an options file may not have been successfully read as follows:
   INFORM = 1
     IOPTNS is not in the range [0,99].
   INFORM = 2
     begin was found, but end-of-file was found before end was found.
   INFORM = 3
     end-of-file was found before begin was found.

6. Error Indicators and Warnings

If a line is not recognised as a valid option, then a warning message is output on the current advisory message unit (see X04ABF).

7. Accuracy
Not applicable.

8. Further Comments

E04DKF may also be used to supply optional parameters to E04DGF.

9. Example

See the example for E04DGF.

Supply individual optional params to E04DGF

--- nage.ht ---
3. Description

E04DKF may be used to supply values for optional parameters to E04DGF. It is only necessary to call E04DKF for those parameters whose values are to be different from their default values. One call to E04DKF sets one parameter value.

Each optional parameter is defined by a single character string of up to 72 characters, consisting of one or more items. The items associated with a given option must be separated by spaces, or equal signs (=). Alphabetic characters may be upper or lower case. The string

\[ \text{Print Level} = 1 \]

is an example of a string used to set an optional parameter. For each option the string contains one or more of the following items:

(a) A mandatory keyword.

(b) A phrase that qualifies the keyword.

(c) A number that specifies an INTEGER or real value. Such numbers may be up to 16 contiguous characters in Fortran 77's I, F, E or D formats, terminated by a space if this is not the last item on the line.

Blank strings and comments are ignored. A comment begins with an asterisk (*) and all subsequent characters in the string are regarded as part of the comment.

Normally, each user-specified option is printed as it is defined, on the current advisory message unit (see X04ABF), but this printing may be suppressed using the keyword nolist. Thus the statement

\[ \text{CALL E04DKF ('Nolist')} \]

suppresses printing of this and subsequent options. Printing will automatically be turned on again after a call to E04DGF, and may be turned on again at any time by the user, by using the keyword list.

Optional parameter settings are preserved following a call to E04DGF, and so the keyword defaults is provided to allow the user to reset all the optional parameters to their default values by the statement,
CALL E04DKF ('Defaults')

prior to a subsequent call to E04DGF.

A complete list of optional parameters, their abbreviations, synonyms and default values is given in Section 5.1 of the routine document for E04DGF.

4. References

None.

5. Parameters

1: STRING -- CHARACTER(*) Input
   On entry: STRING must be a single valid option string. See Section 3 above, and Section 5.1 of the routine document for E04DGF.

6. Error Indicators and Warnings

If the parameter STRING is not recognised as a valid option string, then a warning message is output on the current advisory message unit (see X04ABF).

7. Accuracy

Not applicable.

8. Further Comments

E04DJF may also be used to supply optional parameters to E04DGF.

9. Example

See the example for E04DGF.

Finding an unconstrained minimum of a sum of squares

— nage.ht —
1. Purpose

E04FDF is an easy-to-use algorithm for finding an unconstrained minimum of a sum of squares of m nonlinear functions in n variables (m\geq n). No derivatives are required.

It is intended for functions which are continuous and which have continuous first and second derivatives (although it will usually work even if the derivatives have occasional discontinuities).

2. Specification

```fortran
SUBROUTINE E04FDF (M, N, X, FSUMSQ, IW, LIW, W, LW, IFAIL)
INTEGER M, N, IW(LIW), LIW, LW, IFAIL
DOUBLE PRECISION X(N), FSUMSQ, W(LW)
```

3. Description

This routine is essentially identical to the subroutine LSNDN1 in the National Physical Laboratory Algorithms Library. It is applicable to problems of the form

\[
\begin{align*}
m & \quad -- \quad 2 \\
\text{Minimize } F(x) & \quad > \quad \sum_{i=1}^{m} f_i(x)
\end{align*}
\]

where \( x=(x_1, x_2, \ldots, x_n) \) and \( m\geq n \). (The functions \( f_i(x) \) are often referred to as 'residuals'.) The user must supply a subroutine
LSFUN1 to evaluate functions \( f(x) \) at any point \( x \).

From a starting point supplied by the user, a sequence of points is generated which is intended to converge to a local minimum of the sum of squares. These points are generated using estimates of the curvature of \( F(x) \).

4. References

5. Parameters

1:  M -- INTEGER  
    Input

2:  N -- INTEGER  
    Input
    On entry: the number \( m \) of residuals \( f(x) \), and the number \( n \)
    of variables, \( x \). Constraint: \( 1 \leq N \leq M \).

3:  X(N) -- DOUBLE PRECISION array  
    Input/Output
    On entry: \( X(j) \) must be set to a guess at the \( j \)th component
    of the position of the minimum, for \( j=1,2,\ldots,n \). On exit: the
    lowest point found during the calculations. Thus, if
    IFAIL = 0 on exit, \( X(j) \) is the \( j \)th component of the position
    of the minimum.

4:  FSUMSQ -- DOUBLE PRECISION  
    Output
    On exit: the value of the sum of squares, \( F(x) \),
    corresponding to the final point stored in \( X \).

5:  IW(LIW) -- INTEGER array  
    Workspace

6:  LIW -- INTEGER  
    Input
    On entry: the length of IW as declared in the (sub)program
    from which E04FDF has been called. Constraint: \( LIW \geq 1 \).

7:  W(LW) -- DOUBLE PRECISION array  
    Workspace

8:  LW -- INTEGER  
    Input
    On entry: the length of W as declared in the (sub)program
    from which E04FDF is called. Constraints:
    \[
    LW \geq N \times (7 + N + 2 \times M + (N-1)/2) + 3 \times M, \text{ if } N > 1, \\
    LW \geq 9 + 5 \times M, \text{ if } N = 1.
    \]
CHAPTER 22. NAG LIBRARY ROUTINES

9: IFAIL -- INTEGER

Input/Output

On entry: IFAIL must be set to 0, -1 or 1. Users who are
unfamiliar with this parameter should refer to the Essential
Introduction for details.

On exit: IFAIL = 0 unless the routine detects an error or
gives a warning (see Section 6).

For this routine, because the values of output parameters
may be useful even if IFAIL /=0 on exit, users are
recommended to set IFAIL to -1 before entry. It is then
essential to test the value of IFAIL on exit.

5.1. Optional Parameters

LSFUN1 -- SUBROUTINE, supplied by the user.

External Procedure

This routine must be supplied by the user to calculate the
vector of values \( f(x) \) at any point \( x \). Since the routine is
not a parameter to E04FDF, it must be called LSFUN1. It
should be tested separately before being used in conjunction
with E04FDF (see the Chapter Introduction).

Its specification is:

```fortran
SUBROUTINE LSFUN1 (M, N, XC, FVECC)
INTEGER M, N
DOUBLE PRECISION XC(N), FVECC(M)
```

1: M -- INTEGER Input

2: N -- INTEGER Input

On entry: the numbers \( m \) and \( n \) of residuals and
variables, respectively.

3: XC(N) -- DOUBLE PRECISION array Input

On entry: the point \( x \) at which the values of the \( f_i \)
are required.

4: FVECC(M) -- DOUBLE PRECISION array Output

On exit: FVECC(i) must contain the value of \( f_i \) at the
point \( x \), for \( i=1,2,\ldots,m \).

LSFUN1 must be declared as EXTERNAL in the (sub)program
from which E04FDF is called. Parameters denoted as
Input must not be changed by this procedure.

6. Error Indicators and Warnings
Errors or warnings specified by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1
On entry N < 1,
or M < N,
or LIW < 1,
or LW < N*(7 + N + 2*M + (N-1)/2) + 3*M, when N > 1,
or LW < 9 + 5*M, when N = 1.

IFAIL= 2
There have been 400*n calls of LSFUN1, yet the algorithm does not seem to have converged. This may be due to an awkward function or to a poor starting point, so it is worth restarting E04FDF from the final point held in X.

IFAIL= 3
The final point does not satisfy the conditions for acceptance as a minimum, but no lower point could be found.

IFAIL= 4
An auxiliary routine has been unable to complete a singular value decomposition in a reasonable number of sub-iterations.

IFAIL= 5

IFAIL= 6

IFAIL= 7

IFAIL= 8
There is some doubt about whether the point x found by E04FDF is a minimum of F(x). The degree of confidence in the result decreases as IFAIL increases. Thus when IFAIL = 5, it is probable that the final x gives a good estimate of the position of a minimum, but when IFAIL = 8 it is very unlikely that the routine has found a minimum.

If the user is not satisfied with the result (e.g. because IFAIL lies between 3 and 8), it is worth restarting the calculations from a different starting point (not the point at which the failure occurred) in order to avoid the region which caused the
failure. Repeated failure may indicate some defect in the formulation of the problem.

7. Accuracy

If the problem is reasonably well scaled and a successful exit is made, then, for a computer with a mantissa of \(t\) decimals, one would expect to get about \(t/2-1\) decimals accuracy in the components of \(x\) and between \(t-1\) (if \(F(x)\) is of order 1 at the minimum) and \(2t-2\) (if \(F(x)\) is close to zero at the minimum) decimals accuracy in \(F(x)\).

8. Further Comments

The number of iterations required depends on the number of variables, the number of residuals and their behaviour, and the distance of the starting point from the solution. The number of multiplications performed per iteration of E04FDF varies, but for \(m\gg n\) is approximately \(n^2 m + O(n)\). In addition, each iteration makes at least \(n+1\) calls of LSFUN1. So, unless the residuals can be evaluated very quickly, the run time will be dominated by the time spent in LSFUN1.

Ideally, the problem should be scaled so that the minimum value of the sum of squares is in the range \((0,1)\), and so that at points a unit distance away from the solution the sum of squares is approximately a unit value greater than at the minimum. It is unlikely that the user will be able to follow these recommendations very closely, but it is worth trying (by guesswork), as sensible scaling will reduce the difficulty of the minimization problem, so that E04FDF will take less computer time.

When the sum of squares represents the goodness of fit of a nonlinear model to observed data, elements of the variance-covariance matrix of the estimated regression coefficients can be computed by a subsequent call to E04YCF, using information returned in segments of the workspace array \(W\). See E04YCF for further details.

9. Example

To find least-squares estimates of \(x_1\), \(x_2\) and \(x_3\) in the model

\[
y = x_1 + \frac{1}{x_1 x_2 x_3} \\
1 = x_1 x_2 + x_1 x_3 + x_2 x_3
\]
using the 15 sets of data given in the following table.

\[
\begin{array}{cccc}
 y & t & t & t \\
 1 & 2 & 3 \\
 0.14 & 1.0 & 15.0 & 1.0 \\
 0.18 & 2.0 & 14.0 & 2.0 \\
 0.22 & 3.0 & 13.0 & 3.0 \\
 0.25 & 4.0 & 12.0 & 4.0 \\
 0.29 & 5.0 & 11.0 & 5.0 \\
 0.32 & 6.0 & 10.0 & 6.0 \\
 0.35 & 7.0 & 9.0 & 7.0 \\
 0.39 & 8.0 & 8.0 & 8.0 \\
 0.37 & 9.0 & 7.0 & 7.0 \\
 0.58 & 10.0 & 6.0 & 6.0 \\
 0.73 & 11.0 & 5.0 & 5.0 \\
 0.96 & 12.0 & 4.0 & 4.0 \\
 1.34 & 13.0 & 3.0 & 3.0 \\
 2.10 & 14.0 & 2.0 & 2.0 \\
 4.39 & 15.0 & 1.0 & 1.0 \\
\end{array}
\]

The program uses \((0.5, 1.0, 1.5)\) as the initial guess at the position of the minimum.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
E04 -- Minimizing or Maximizing a Function

E04GCF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E04GCF is an easy-to-use quasi-Newton algorithm for finding an unconstrained minimum of a sum of squares of m nonlinear functions in n variables (m>=n). First derivatives are required.

It is intended for functions which are continuous and which have continuous first and second derivatives (although it will usually work even if the derivatives have occasional discontinuities).

2. Specification

SUBROUTINE E04GCF (M, N, X, FSUMSQ, IW, LIW, W, LW, IFAIL)

INTEGER M, N, IW(LIW), LIW, LW, IFAIL
DOUBLE PRECISION X(N), FSUMSQ, W(LW)

3. Description

This routine is essentially identical to the subroutine LSFDQ2 in the National Physical Laboratory Algorithms Library. It is applicable to problems of the form

\[ \minimize_{x} \sum_{i=1}^{m} f(x) \]

where \( x = (x_1, x_2, \ldots, x_n) \) and \( m \geq n \). (The functions \( f(x) \) are often referred to as ‘residuals’.) The user must supply a subroutine LSFUN2 to evaluate the residuals and their first derivatives at any point \( x \).

Before attempting to minimize the sum of squares, the algorithm checks LSFUN2 for consistency. Then, from a starting point supplied by the user, a sequence of points is generated which is intended to converge to a local minimum of the sum of squares. These points are generated using estimates of the curvature of
22.4. NAGE.HT

F(x).

4. References

5. Parameters

1: M -- INTEGER Input
2: N -- INTEGER Input
On entry: the number m of residuals f(x), and the number n
of variables, x. Constraint: 1 <= N <= M.

3: X(N) -- DOUBLE PRECISION array Input/Output
On entry: X(j) must be set to a guess at the jth component of the position of the minimum, for j=1,2,...,n. The routine checks the first derivatives calculated by LSFUN2 at the starting point, and so is more likely to detect an error in the user's routine if the initial X(j) are non-zero and mutually distinct. On exit: the lowest point found during the calculations. Thus, if IFAIL = 0 on exit, X(j) is the j th component of the position of the minimum.

4: FSUMSQ -- DOUBLE PRECISION Output
On exit: the value of the sum of squares, F(x), corresponding to the final point stored in X.

5: IW(LIW) -- INTEGER array Workspace
6: LIW -- INTEGER Input
On entry: the length of IW as declared in the (sub)program from which E04GCF is called. Constraint: LIW >= 1.

7: W(LW) -- DOUBLE PRECISION array Workspace
8: LW -- INTEGER Input
On entry: the length of W as declared in the (sub)program from which E04GCF is called. Constraints:
\[ \text{LW} \geq 2 \times N \times (4 + N + M) + 3 \times M, \text{ if } N > 1, \]
\[ \text{LW} \geq 11 + 5 \times M, \text{ if } N = 1. \]

9: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. Users who are unfamiliar with this parameter should refer to the Essential
CHAPTER 22. NAG LIBRARY ROUTINES

Introduction for details.

On exit: IFAIL = 0 unless the routine detects an error or gives a warning (see Section 6).

For this routine, because the values of output parameters may be useful even if IFAIL /=0 on exit, users are recommended to set IFAIL to -1 before entry. It is then essential to test the value of IFAIL on exit.

5.1. Optional Parameters

LSFUN2 -- SUBROUTINE, supplied by the user.

External Procedure

This routine must be supplied by the user to calculate the vector of values f (x) and the Jacobian matrix of first

\[ \frac{df_i}{dx_j} \]

derivatives ---- at any point x. Since the routine is not a parameter to E04GCF, it must be called LSFUN2. It should be tested separately before being used in conjunction with E04GCF (see the Chapter Introduction).

Its specification is:

```fortran
SUBROUTINE LSFUN2 (M, N, XC, FVECC, FJACC, LJC)
    INTEGER M, N, LJC
    DOUBLE PRECISION XC(N), FVECC(M), FJACC(LJC,N)
```

Important: The dimension declaration for FJACC must contain the variable LJC, not an integer constant.

1: M -- INTEGER Input
2: N -- INTEGER Input
   On entry: the numbers m and n of residuals and variables, respectively.
3: XC(N) -- DOUBLE PRECISION array Input
   On entry: the point x at which the values of the f
   \[ \frac{df_i}{dx_j} \]
   and the ---- are required.
   \[ \frac{df_i}{dx_j} \]
4: FVECC(M) -- DOUBLE PRECISION array Output
On exit: FVECC(i) must contain the value of $f$ at the point $x$, for $i=1,2,\ldots,m$.

5: FJACC(LJC,N) -- DOUBLE PRECISION array
On exit: FJACC(i,j) must contain the value of $\frac{df}{dx}$ at the point $x$, for $i=1,2,\ldots,m; j=1,2,\ldots,n$.

6: LJC -- INTEGER
On entry: the first dimension of the array FJACC.
LSFUN2 must be declared as EXTERNAL in the (sub)program from which E04GCF is called. Parameters denoted as Input must not be changed by this procedure.

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL = 1
On entry $N < 1$,
or $M < N$,
or LIW < 1,
or $LW < 2*N*(4 + N + M) + 3*M$, when $N > 1$,
or $LW < 9 + 5*\max(M)$, when $N = 1$.

IFAIL = 2
There have been $50n$ calls of LSFUN2, yet the algorithm does not seem to have converged. This may be due to an awkward function or to a poor starting point, so it is worth restarting E04GCF from the final point held in $X$.

IFAIL = 3
The final point does not satisfy the conditions for acceptance as a minimum, but no lower point could be found.

IFAIL = 4
An auxiliary routine has been unable to complete a singular value decomposition in a reasonable number of sub-iterations.
CHAPTER 22. NAG LIBRARY Routines

IFAIL = 5

IFAIL = 6

IFAIL = 7

IFAIL = 8
There is some doubt about whether the point X found by E04GCF is a minimum of F(x). The degree of confidence in the result decreases as IFAIL increases. Thus, when IFAIL = 5, it is probable that the final x gives a good estimate of the position of a minimum, but when IFAIL = 8 it is very unlikely that the routine has found a minimum.

IFAIL = 9
It is very likely that the user has made an error in forming ddf
    i
the derivatives ---- in LSFUN2.
ddx
    j

If the user is not satisfied with the result (e.g. because IFAIL lies between 3 and 8), it is worth restarting the calculations from a different starting point (not the point at which the failure occurred) in order to avoid the region which caused the failure. Repeated failure may indicate some defect in the formulation of the problem.

7. Accuracy

If the problem is reasonably well scaled and a successful exit is made then, for a computer with a mantissa of t decimals, one would expect to get t/2-1 decimals accuracy in the components of x and between t-1 (if F(x) is of order 1 at the minimum) and 2t-2 (if F(x) is close to zero at the minimum) decimals accuracy in F(x).

8. Further Comments

The number of iterations required depends on the number of variables, the number of residuals and their behaviour, and the distance of the starting point from the solution. The number of multiplications performed per iteration of E04GCF varies, but for 2 3
m>>n is approximately n*m +O(n ). In addition, each iteration makes at least one call of LSFUN2. So, unless the residuals and their derivatives can be evaluated very quickly, the run time will be dominated by the time spent in LSFUN2.
Ideally the problem should be scaled so that the minimum value of the sum of squares is in the range \((0,1)\) and so that at points a unit distance away from the solution the sum of squares is approximately a unit value greater than at the minimum. It is unlikely that the user will be able to follow these recommendations very closely, but it is worth trying (by guesswork), as sensible scaling will reduce the difficulty of the minimization problem, so that E04GCF will take less computer time.

When the sum of squares represents the goodness of fit of a nonlinear model to observed data, elements of the variance-covariance matrix of the estimated regression coefficients can be computed by a subsequent call to E04YCF, using information returned in segments of the workspace array \(W\). See E04YCF for further details.

9. Example

To find the least-squares estimates of \(x\), \(x\), and \(x\) in the model

\[
y = x_1 + \frac{1}{x_1 \times x_2 + x_3}
\]

using the 15 sets of data given in the following table.

The program uses \((0.5, 1.0, 1.5)\) as the initial guess at the
Finding a minimum of a function

--- nage.ht ---

E04JAF is an easy-to-use quasi-Newton algorithm for finding a minimum of a function $F(x_1, x_2, \ldots, x_n)$, subject to fixed upper and lower bounds of the independent variables $x_1, x_2, \ldots, x_n$, using function values only.

It is intended for functions which are continuous and which have continuous first and second derivatives (although it will usually work even if the derivatives have occasional discontinuities).
2. Specification

SUBROUTINE E04JAF (N, IBOUND, BL, BU, X, F, IW, LIW, W, LW, IFAIL)
  INTEGER N, IBOUND, IW(LIW), LIW, LW, IFAIL
  DOUBLE PRECISION BL(N), BU(N), X(N), F, W(LW)

3. Description

This routine is applicable to problems of the form:

Minimize $F(x_1, x_2, ..., x_n)$ subject to $l_j \leq x_j \leq u_j$, $j=1,2,...,n$

when derivatives of $F(x)$ are unavailable.

Special provision is made for problems which actually have no bounds on the $x_j$, problems which have only non-negativity bounds $x_j$ and problems in which $l_1 = l_2 = ... = l_n$ and $u_1 = u_2 = ... = u_n$. The user must supply a subroutine FUNCT1 to calculate the value of $F(x)$ at any point $x$.

From a starting point supplied by the user there is generated, on the basis of estimates of the gradient and the curvature of $F(x)$, a sequence of feasible points which is intended to converge to a local minimum of the constrained function. An attempt is made to verify that the final point is a minimum.

4. References

5. Parameters

1: N -- INTEGER
   Input
   On entry: the number $n$ of independent variables.
   Constraint: $N \geq 1$.

2: IBOUND -- INTEGER
   Input
   On entry: indicates whether the facility for dealing with bounds of special forms is to be used.
   It must be set to one of the following values:
   IBOUND = 0
     if the user will be supplying all the $l_j$ and $u_j$
     $j$ $j$
individually.

\[ \text{IBOUND} = 1 \]
if there are no bounds on any \( x \).

\[ \text{IBOUND} = 2 \]
if all the bounds are of the form \( 0 \leq x \).

\[ \text{IBOUND} = 3 \]
if \( l_1 = l_2 = \ldots = l_n \) and \( u_1 = u_2 = \ldots = u_n \).

3: \( \text{BL(N)} \) -- DOUBLE PRECISION array Input/Output
On entry: the lower bounds \( l \).
\[ j \]

If IBOUND is set to 0, the user must set \( \text{BL}(j) \) to \( l \), for \( j = 1, 2, \ldots, n \). (If a lower bound is not specified for a particular \( x \), the corresponding \( \text{BL}(j) \) should be set to \( -10 \).)

If IBOUND is set to 3, the user must set \( \text{BL}(1) \) to \( l \); E04JAF will then set the remaining elements of BL equal to \( \text{BL}(1) \).
On exit: the lower bounds actually used by E04JAF.

4: \( \text{BU(N)} \) -- DOUBLE PRECISION array Input/Output
On entry: the upper bounds \( u \).
\[ j \]

If IBOUND is set to 0, the user must set \( \text{BU}(j) \) to \( u \), for \( j = 1, 2, \ldots, n \). (If an upper bound is not specified for a particular \( x \), the corresponding \( \text{BU}(j) \) should be set to \( 10 \).)

If IBOUND is set to 3, the user must set \( \text{BU}(1) \) to \( u \); E04JAF will then set the remaining elements of BU equal to \( \text{BU}(1) \).
On exit: the upper bounds actually used by E04JAF.

5: \( \text{X(N)} \) -- DOUBLE PRECISION array Input/Output
On entry: \( X(j) \) must be set to an estimate of the \( j \)th component of the position of the minimum, for \( j = 1, 2, \ldots, n \).
On exit: the lowest point found during the calculations.
Thus, if IFAIL = 0 on exit, X(j) is the jth component of the position of the minimum.

6: F -- DOUBLE PRECISION Output
On exit: the value of F(x) corresponding to the final point stored in X.

7: IW(LIW) -- INTEGER array Workspace
8: LIW -- INTEGER Input
On entry: the length of IW as declared in the (sub)program from which E04JAF is called. Constraint: LIW >= N + 2.

9: W(LW) -- DOUBLE PRECISION array Workspace
10: LW -- INTEGER Input
On entry: the length of W as declared in the (sub)program from which E04JAF is called. Constraint: LW >= max(N*(N-1)/2+12*N,13).

11: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. Users who are unfamiliar with this parameter should refer to the Essential Introduction for details.

On exit: IFAIL = 0 unless the routine detects an error or gives a warning (see Section 6).

For this routine, because the values of output parameters may be useful even if IFAIL /=0 on exit, users are recommended to set IFAIL to -1 before entry. It is then essential to test the value of IFAIL on exit. To suppress the output of an error message when soft failure occurs, set IFAIL to 1.

5.1. Optional Parameters

FUNCT1 -- SUBROUTINE, supplied by the user.

External Procedure
This routine must be supplied by the user to calculate the value of the function F(x) at any point x. Since this routine is not a parameter to E04JAF, it must be called FUNCT1. It should be tested separately before being used in conjunction with E04JAF (see the Chapter Introduction).

Its specification is:

SUBROUTINE FUNCT1 (N, XC, FC)
INTEGER N
DOUBLE PRECISION XC(N), FC
1: N -- INTEGER Input
   On entry: the number n of variables.

2: XC(N) -- DOUBLE PRECISION array Input
   On entry: the point x at which the function value is
   required.

3: FC -- DOUBLE PRECISION Output
   On exit: the value of the function F at the current
   point x.

FUNCT1 must be declared as EXTERNAL in the (sub)program
from which E04JAF is called. Parameters denoted as
Input must not be changed by this procedure.

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

IFAIL= 1
On entry N < 1,
   or IBOUND < 0,
   or IBOUND > 3,
   or IBOUND = 0 and BL(j) > BU(j) for some j,
   or IBOUND = 3 and BL(1) > BU(1),
   or LIW < N + 2,
   or LW<max(13,12*N+N*(N-1)/2).

IFAIL= 2
There have been 400*n function evaluations, yet the
algorithm does not seem to be converging. The calculations
can be restarted from the final point held in X. The error
may also indicate that F(x) has no minimum.

IFAIL= 3
The conditions for a minimum have not all been met but a
lower point could not be found and the algorithm has failed.

IFAIL= 4
An overflow has occurred during the computation. This is an
unlikely failure, but if it occurs the user should restart
at the latest point given in X.

IFAIL= 5
IFAIL= 6

IFAIL= 7

IFAIL= 8

There is some doubt about whether the point $x$ found by E04JAF is a minimum. The degree of confidence in the result decreases as IFAIL increases. Thus, when IFAIL = 5 it is probable that the final $x$ gives a good estimate of the position of a minimum, but when IFAIL = 8 it is very unlikely that the routine has found a minimum.

IFAIL= 9

In the search for a minimum, the modulus of one of the 6 variables has become very large (~$10^6$). This indicates that there is a mistake in FUNCT1, that the user's problem has no finite solution, or that the problem needs rescaling (see Section 8).

If the user is dissatisfied with the result (e.g. because IFAIL = 5, 6, 7 or 8), it is worth restarting the calculations from a different starting point (not the point at which the failure occurred) in order to avoid the region which caused the failure. If persistent trouble occurs and the gradient can be calculated, it may be advisable to change to a routine which uses gradients (see the Chapter Introduction).

7. Accuracy

When a successful exit is made then, for a computer with a mantissa of $t$ decimals, one would expect to get about $t/2 - 1$ decimals accuracy in $x$ and about $t - 1$ decimals accuracy in $F$, provided the problem is reasonably well scaled.

8. Further Comments

The number of iterations required depends on the number of variables, the behaviour of $F(x)$ and the distance of the starting point from the solution. The number of operations performed in an iteration of E04JAF is roughly proportional to $n$. In addition, each iteration makes at least $m+1$ calls of FUNCT1, where $m$ is the number of variables not fixed on bounds. So, unless $F(x)$ can be evaluated very quickly, the run time will be dominated by the time spent in FUNCT1.

Ideally the problem should be scaled so that at the solution the value of $F(x)$ and the corresponding values of $x_1, x_2, \ldots, x_n$ are
each in the range (-1,+1), and so that at points a unit distance away from the solution, F is approximately a unit value greater than at the minimum. It is unlikely that the user will be able to follow these recommendations very closely, but it is worth trying (by guesswork), as sensible scaling will reduce the difficulty of the minimization problem, so that E04JAF will take less computer time.

9. Example

To minimize

\[
F = (x + 10x_1^2 + 5(x_2 - x_3) + (x_4 - 2x_3) + 10(x_3 - x_4))
\]

subject to

1. \[1 \leq x_1 \leq 3\]
2. \[-2 \leq x_2 \leq 0\]
3. \[1 \leq x_3 \leq 3,\]
4. \[1 \leq x_4 \leq 3,\]

starting from the initial guess (3, -1, 0, 1).

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

E04 -- Minimizing or Maximizing a Function

E04MBF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E04MBF is an easy-to-use routine for solving linear programming problems, or for finding a feasible point for such problems. It is not intended for large sparse problems.

2. Specification

```fortran
SUBROUTINE E04MBF (ITMAX, MSGLVL, N, NCLIN, NCTOTL, NROWA, A, BL, BU, CVEC, LINOBJ, X, ISTATE,
1 OBJLP, CLAMDA, IWORK, LIWORK, WORK,
2 LWORK, IFAIL)

INTEGER ITMAX, MSGLVL, N, NCLIN, NCTOTL, NROWA,
1 ISTATE(NCTOTL), IWORK(LIWORK), LIWORK,
2 LWORK, IFAIL

DOUBLE PRECISION A(NROWA,N), BL(NCTOTL), BU(NCTOTL), CVEC
1 (N), X(N), OBJLP, CLAMDA(NCTOTL), WORK
2 (LWORK)

LOGICAL LINOBJ
```

3. Description

E04MBF solves linear programming (LP) problems of the form

\[
\text{Minimize } \quad c^T x \quad \text{subject to } \quad l \leq (Ax) \leq u \quad \text{(LP)}
\]

\[n \quad x \text{ is in } \mathbb{R}\]

where \(c\) is an \(n\) element vector and \(A\) is an \(m\) by \(n\) matrix i.e., there are \(n\) variables and \(m\) general linear constraints. \(m\) may be zero in which case the LP problem is subject only to bounds on the variables. Notice that upper and lower bounds are specified for all the variables and constraints. This form allows full generality in specifying other types of constraints. For example
the \( i \)th constraint may be specified as equality by setting \( l = u \).

If certain bounds are not present the associated elements of \( l \) or \( u \) can be set to special values that will be treated as -infty or +infty.

The routine allows the linear objective function to be omitted in which case a feasible point for the set of constraints is sought.

The user must supply an initial estimate of the solution.

Users who wish to exercise additional control and users with problems whose solution would benefit from additional flexibility should consider using the comprehensive routine E04NAF.

4. References

5. Parameters

1: ITMAX -- INTEGER Input
   On entry: an upper bound on the number of iterations to be taken. If ITMAX is not positive, then the value 50 is used in place of ITMAX.

2: MSGLVL -- INTEGER Input
   On entry: indicates whether or not printout is required at the final solution. When printing occurs the output is on the advisory message channel (see X04ABF). A description of the printed output is given in Section 5.1. The level of printing is determined as follows:
   MSGLVL < 0
      No printing.
   MSGLVL = 0
      Printing only if an input parameter is incorrect, or if the problem is so ill-conditioned that subsequent overflow is likely. This setting is strongly recommended in preference to MSGLVL < 0.
   MSGLVL = 1
      Printing at the solution.
   MSGLVL > 1
Values greater than 1 should normally be used only at the direction of NAG; such values may generate large amounts of printed output.

3: N -- INTEGER  

4: NCLIN -- INTEGER  
   On entry: the number of general linear constraints in the problem. Constraint: NCLIN >= 0.

5: NCTOTL -- INTEGER  
   On entry: the value (N+NCLIN).

6: NROWA -- INTEGER  
   On entry: the first dimension of the array A as declared in the (sub)program from which E04MBF is called. Constraint: NROWA >= max(1,NCLIN).

7: A(NROWA,N) -- DOUBLE PRECISION array  
   On entry: the leading NCLIN by n part of A must contain the NCLIN general constraints, with the coefficients of the ith constraint in the ith row of A. If NCLIN = 0, then A is not referenced.

8: BL(NCTOTL) -- DOUBLE PRECISION array  
   On entry: the first n elements of BL must contain the lower bounds on the n variables, and when NCLIN > 0, the next NCLIN elements of BL must contain the lower bounds on the NCLIN general linear constraints. To specify a non-existent lower bound (l = -infty), set BL(j) <= -1.0E+20.

9: BU(NCTOTL) -- DOUBLE PRECISION array  
   On entry: the first n elements of BU must contain the upper bounds on the n variables, and when NCLIN > 0, the next NCLIN elements of BU must contain the upper bounds on the NCLIN general linear constraints. To specify a non-existent upper bound (u = +infty), set BU(j) >= 1.0E+20. Constraint: BL(j) <= BU(j), for j=1,2,...,NCTOTL.

10: CVEC(N) -- DOUBLE PRECISION array  
    On entry: with LINOBJ = .TRUE., CVEC must contain the coefficients of the objective function. If LINOBJ = .FALSE., then CVEC is not referenced.

11: LINOBJ -- LOGICAL  
    On entry: indicates whether or not a linear objective
function is present. If LINOBJ = .TRUE., then the full LP problem is solved, but if LINOBJ = .FALSE., only a feasible point is found and the array CVEC is not referenced.

12: \( X(n) \) -- DOUBLE PRECISION array Input/Output
On entry: an estimate of the solution, or of a feasible point. Even when LINOBJ = .TRUE. it is not necessary for the point supplied in \( X \) to be feasible. In the absence of better information all elements of \( X \) may be set to zero. On exit: the solution to the LP problem when LINOBJ = .TRUE., or a feasible point when LINOBJ = .FALSE..

When no feasible point exists (see IFAIL = 1 in Section 6) then \( X \) contains the point for which the sum of the infeasibilities is a minimum. On return with IFAIL = 2, 3 or 4, \( X \) contains the point at which E04MBF terminated.

13: \( \text{ISTATE}(nctotl) \) -- INTEGER array Output
On exit: with IFAIL < 5, ISTATE indicates the status of every constraint at the final point. The first \( n \) elements of ISTATE refer to the upper and lower bounds on the variables and when NCLIN > 0 the next NCLIN elements refer to the general constraints.

Their meaning is:

\begin{align*}
\text{ISTATE}(j) & \quad \text{Meaning} \\
-2 & \quad \text{The constraint violates its lower bound. This value cannot occur for any element of ISTATE when a feasible point has been found.} \\
-1 & \quad \text{The constraint violates its upper bound. This value cannot occur for any element of ISTATE when a feasible point has been found.} \\
0 & \quad \text{The constraint is not in the working set (is not active) at the final point. Usually this means that the constraint lies strictly between its bounds.} \\
1 & \quad \text{This inequality constraint is in the working set (is active) at its lower bound.} \\
2 & \quad \text{This inequality constraint is in the working set (is active) at its upper bound.} \\
3 & \quad \text{This constraint is included in the working set (is active) as an equality. This value can only occur when BL(j) = BU(j).}
\end{align*}
14: OBJLP -- DOUBLE PRECISION          Output
On exit: when LINOBJ = .TRUE., then on successful exit,
OBJLP contains the value of the objective function at the
solution, and on exit with IFAIL = 2, 3 or 4, OBJLP contains
the value of the objective function at the point returned in
X.

When LINOBJ = .FALSE., then on successful exit OBJLP will be
zero and on return with IFAIL = 1, OBJLP contains the
minimum sum of the infeasibilities corresponding to the
point returned in X.

15: CLAMDA(NCTOTL) -- DOUBLE PRECISION array          Output
On exit: when LINOBJ = .TRUE., then on successful exit, or
on exit with IFAIL = 2, 3, or 4, CLAMDA contains the
Lagrange multipliers (reduced costs) for each constraint
with respect to the working set. The first n components of
CLAMDA contain the multipliers for the bound constraints on
the variables and the remaining NCLIN components contain the
multipliers for the general linear constraints.

If ISTATE(j) = 0 so that the jth constraint is not in the
working set then CLAMDA(j) is zero. If X is optimal and
ISTATE(j) = 1, then CLAMDA(j) should be non-negative, and if
ISTATE(j) = 2, then CLAMDA(j) should be non-positive.

When LINOBJ = .FALSE., all NCTOTL elements of CLAMDA are
returned as zero.

16: IWORK(LIWORK) -- INTEGER array          Workspace

17: LIWORK -- INTEGER          Input
On entry: the length of the array IWORK as declared in the
(sub)program from which E04MBF is called. Constraint:
LIWORK>=2*N.

18: WORK(LWORK) -- DOUBLE PRECISION array          Workspace

19: LWORK -- INTEGER          Input
On entry: the length of the array WORK as declared in the
(sub)program from which E04MBF is called. Constraints:
when N <= NCLIN then
2
LWORK>=2*N +6*N+4*NCLIN+NROWA;

when 0 <= NCLIN < N then
2
LWORK>=2*(NCLIN+1) +4*NCLIN+6*N+NROWA.

20: IFAIL -- INTEGER          Input/Output
On entry: IFAIL must be set to 0, -1 or 1. Users who are unfamiliar with this parameter should refer to the Essential Introduction for details.

On exit: IFAIL = 0 unless the routine detects an error or gives a warning (see Section 6).

For this routine, because the values of output parameters may be useful even if IFAIL /=0 on exit, users are recommended to set IFAIL to -1 before entry. It is then essential to test the value of IFAIL on exit. To suppress the output of an error message when soft failure occurs, set IFAIL to 1.

5.1. Description of the Printed Output

When MSGGLVL = 1, then E04MBF will produce output on the advisory message channel (see X04ABF ), giving information on the final point. The following describes the printout associated with each variable.

<table>
<thead>
<tr>
<th>Output</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>VARBL</td>
<td>The name (V) and index j, for j=1,2,...,n, of the variable.</td>
</tr>
<tr>
<td>STATE</td>
<td>The state of the variable. (FR if neither bound is in the working set, EQ for a fixed variable, LL if on its lower bound, UL if on its upper bound and TB if held on a temporary bound.) If the value of the variable lies outside the upper or lower bound then STATE will be ++ or -- respectively.</td>
</tr>
<tr>
<td>VALUE</td>
<td>The value of the variable at the final iteration.</td>
</tr>
<tr>
<td>LOWER BOUND</td>
<td>The lower bound specified for the variable.</td>
</tr>
<tr>
<td>UPPER BOUND</td>
<td>The upper bound specified for the variable.</td>
</tr>
<tr>
<td>LAGR MUL</td>
<td>The value of the Lagrange multiplier for the associated bound.</td>
</tr>
<tr>
<td>RESIDUAL</td>
<td>The difference between the value of the variable and the nearer of its bounds.</td>
</tr>
</tbody>
</table>

For each of the general constraints the printout is as above with refers to the jth element of Ax, except that VARBL is replaced by:

| LNCON | The name (L) and index j, for j = 1,2,...,NCLIN of                     |
the constraint.

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

Note: when MSGLVL=1 a short description of the error is printed.

IFAIL= 1
No feasible point could be found. Moving violated
constraints so that they are satisfied at the point returned
in X gives the minimum moves necessary to make the LP
problem feasible.

IFAIL= 2
The solution to the LP problem is unbounded.

IFAIL= 3
A total of 50 changes were made to the working set without
altering x. Cycling is probably occurring. The user should
consider using E04NAF with MSGLVL \geq 5 to monitor constraint
additions and deletions in order to determine whether or not
cycling is taking place.

IFAIL= 4
The limit on the number of iterations has been reached.
Increase ITMAX or consider using E04NAF to monitor progress.

IFAIL= 5
An input parameter is invalid. Unless MSGLVL < 0 a message
will be printed.

IFAILOverflow
If the printed output before the overflow occurred contains
a warning about serious ill-conditioning in the working set
when adding the jth constraint, then either the user should
try using E04NAF and experiment with the magnitude of FEATOL
(j) in that routine, or the offending linearly dependent
constraint (with index j) should be removed from the
problem.

7. Accuracy

The routine implements a numerically stable active set strategy
and returns solutions that are as accurate as the condition of
the LP problem warrants on the machine.

8. Further Comments

The time taken by each iteration is approximately proportional to
Sensible scaling of the problem is likely to reduce the number of iterations required and make the problem less sensitive to perturbations in the data, thus improving the condition of the LP problem. In the absence of better information it is usually sensible to make the Euclidean lengths of each constraint of comparable magnitude. See Gill et al [1] for further information and advice.

Note that the routine allows constraints to be violated by an absolute tolerance equal to the machine precision (see X02AJF(*))

9. Example

To minimize the function

\[-0.02x_1 -0.2x_2 -0.2x_3 -0.2x_4 -0.2x_5 +0.04x_6 +0.04x_7\]

subject to the bounds

\[-0.01 \leq x_1 \leq 0.01,\]
\[-0.1 \leq x_2 \leq 0.15,\]
\[-0.01 \leq x_3 \leq 0.03,\]
\[-0.04 \leq x_4 \leq 0.02,\]
\[-0.1 \leq x_5 \leq 0.05,\]
\[-0.01 \leq x_6,\]
\[-0.01 \leq x_7\]

and the general constraints

\[x_1 + x_2 + x_3 + x_4 + x_5 + x_6 + x_7 = -0.13\]
\[0.15x_1 + 0.04x_2 + 0.02x_3 + 0.04x_4 + 0.02x_5 + 0.01x_6 + 0.03x_7 \leq -0.0049\]
\[0.03x_1 + 0.05x_2 + 0.08x_3 + 0.02x_4 + 0.06x_5 + 0.01x_6 \leq -0.0064\]
\[0.02x_1 + 0.04x_2 + 0.01x_3 + 0.02x_4 \leq -0.0037\]
1  2  3  4  5  6

0.02x + 0.03x + 0.01x <= -0.0012
1  2  5

-0.0992 <= 0.70x + 0.75x + 0.80x + 0.75x + 0.80x + 0.97x
1  2  3  4  5  6  7

-0.003 <= 0.02x + 0.08x + 0.12x + 0.02x + 0.01x + 0.97x <= 0.002
1  2  3  4  5  6  7

The initial point, which is infeasible, is

\[ \mathbf{x} = (-0.01, -0.03, 0.0, -0.01, -0.1, 0.02, 0.01) \]

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

---

Solving linear or quadratic problems
not included in the Foundation Library.

1. Purpose

E04NAF is a comprehensive routine for solving quadratic programming (QP) or linear programming (LP) problems. It is not intended for large sparse problems.

2. Specification

```fortran
SUBROUTINE E04NAF (ITMAX, MSGLVL, N, NCLIN, NCTOTL, NROWA,
  1 NROWH, NCOLH, BIGBND, A, BL, BU, CVEC,
  2 FEATOL, HESS, QPHESS, COLD, LP, ORTHOG,
  3 X, ISTATE, ITER, OBJ, CLAMDA, IWORK,
  4 LIWORK, WORK, LWORK, IFAIL)

INTEGER ITMAX, MSGLVL, N, NCLIN, NCTOTL, NROWA,
  1 NROWH, NCOLH, ISTATE(NCTOTL), ITER, IWORK
  2 (LIWORK), LIWORK, LWORK, IFAIL

DOUBLE PRECISION BIGBND, A(NROWA,N), BL(NCTOTL),
  1 BU(NCTOTL), CVEC(N), FEATOL(NCTOTL), HESS
  2 (NROWH,NCOLH), X(N), OBJ, CLAMDA(NCTOTL),
  3 WORK(LWORK)

LOGICAL COLD, LP, ORTHOG

EXTERNAL QPHESS
```

3. Description

E04NAF is essentially identical to the subroutine SOL/QPSOL described in Gill et al [1].

E04NAF is designed to solve the quadratic programming (QP) problem - the minimization of a quadratic function subject to a set of linear constraints on the variables. The problem is assumed to be stated in the following form:

\[
\begin{align*}
\text{Minimize} & \quad c^T x + \frac{1}{2} x^T H x \\
\text{subject to} & \quad \lambda \leq (Ax) \leq \mu
\end{align*}
\]

where \( c \) is a constant \( n \)-vector and \( H \) is a constant \( n \times n \) symmetric matrix; note that \( H \) is the Hessian matrix (matrix of second partial derivatives) of the quadratic objective function. The matrix \( A \) is \( m \times n \), where \( m \) may be zero; \( A \) is treated as a dense matrix.

The constraints involving \( A \) will be called the general constraints. Note that upper and lower bounds are specified for all the variables and for all the general constraints. The form of (1) allows full generality in specifying other types of constraints. In particular, an equality constraint is specified
by setting $l_i = u_i$. If certain bounds are not present, the
associated elements of $l$ or $u$ can be set to special values that
will be treated as $-\infty$ or $+\infty$.

The user must supply an initial estimate of the solution to (1),
and a subroutine that computes the product $Hx$ for any given
vector $x$. If $H$ is positive-definite or positive semi-definite,
E04NAF will obtain a global minimum; otherwise, the solution
obtained will be a local minimum (which may or may not be a
global minimum). If $H$ is defined as the zero matrix, E04NAF will
solve the resulting linear programming (LP) problem; however,
this can be accomplished more efficiently by setting a logical
variable in the call of the routine (see the parameter LP in
Section 5).

E04NAF allows the user to provide the indices of the constraints
that are believed to be exactly satisfied at the solution. This
facility, known as a warm start, can lead to significant savings
in computational effort when solving a sequence of related
problems.

The method has two distinct phases. In the first (the LP phase),
an iterative procedure is carried out to determine a feasible
point. In this context, feasibility is defined by a user-provided
array FEATOL; the $j$th constraint is considered satisfied if its
violation does not exceed $\text{FEATOL}(j)$. The second phase (the QP
phase) generates a sequence of feasible iterates in order to
minimize the quadratic objective function. In both phases, a
subset of the constraints - called the working set - is used to
define the search direction at each iteration; typically, the
working set includes constraints that are satisfied to within the
corresponding tolerances in the FEATOL array.

We now briefly describe a typical iteration in the QP phase. Let
$x$ denote the estimate of the solution at the $k$th iteration; the
next iterate is defined by

$$x_{k+1} = x_k + \alpha_k p_k$$

where $p_k$ is an $n$-dimensional search direction and $\alpha_k$ is a
scalar step length. Assume that the working (active) set contains
t linearly independent constraints, and let $C_k$ denote the matrix
of coefficients of the bounds and general constraints in the
current working set.
Let $Z$ denote a matrix whose columns form a basis for the null

space of $C$, so that $CZ = 0$. (Note that $Z$ has $n$ columns, where

$\text{dim } Z = n - t$.) The vector $Z^T(c + Hx)$ is called the projected gradient

$Z$ at $x$. If the projected gradient is zero at $x$ (i.e., $x$ is a

constrained stationary point in the subspace defined by $Z$),

Lagrange multipliers ($\lambda$) are defined as the solution of the

compatible overdetermined system

$$T^{\top}C(\lambda) = c + Hx$$

(2)

The Lagrange multiplier ($\lambda$) corresponding to an inequality

constraint in the working set is said to be optimal if

$(\lambda) \leq 0$ when the associated constraint is at its upper bound,

or if $(\lambda) \geq 0$ when the associated constraint is at its lower

bound. If a multiplier is non-optimal, the objective function can

be reduced by deleting the corresponding constraint (with index

$JDEL$, see Section 5.1) from the working set.

If the projected gradient at $x$ is non-zero, the search direction

$p$ is defined as

$$p = Z^T p$$

(3)

where $p$ is an $n$-vector. In effect, the constraints in the

working set are treated as equalities, by constraining $p$ to lie

within the subspace of vectors orthogonal to the rows of $C$. This

definition ensures that $Cp = 0$, and hence the values of the

constraints in the working set are not altered by any move along

$p$.

The vector $p$ is obtained by solving the equations

$$
\[ Z^T H Z p = -Z (c+Hx) \quad (4) \]

(The matrix \( Z^T H Z \) is called the projected Hessian matrix.) If the projected Hessian is positive-definite, the vector defined by (3) and (4) is the step to the minimum of the quadratic function in the subspace defined by \( Z \).

If the projected Hessian is positive-definite and \( x+p \) is feasible, \((\text{alpha})\) will be taken as unity. In this case, the projected gradient at \( x \) will be zero (see NORM \( Z^T G \) in Section 5.1), and Lagrange multipliers can be computed (see Gill et al [2]). Otherwise, \((\text{alpha})\) is set to the step to the 'nearest' constraint (with index \( \text{JADD} \), see Section 5.1), which is added to the working set at the next iteration.

The matrix \( Z \) is obtained from the TQ factorization of \( C \), in which \( C \) is represented as

\[ C Q = (0 \ T) \quad (5) \]

where \( T \) is reverse-triangular. It follows from (5) that \( Z \) may be taken as the first \( n \) columns of \( Q \). If the projected Hessian is positive-definite, (3) is solved using the Cholesky factorization

\[ Z^T H Z = R^T R \]

where \( R \) is upper triangular. These factorizations are updated as constraints enter or leave the working set (see Gill et al [2] for further details).

An important feature of E04NAF is the treatment of indefiniteness in the projected Hessian. If the projected Hessian is positive-
definite, it may become indefinite only when a constraint is deleted from the working set. In this case, a temporary modification (of magnitude HESS MOD, see Section 5.1) is added to the last diagonal element of the Cholesky factor. Once a modification has occurred, no further constraints are deleted from the working set until enough constraints have been added so that the projected Hessian is again positive-definite. If equation (1) has a finite solution, a move along the direction obtained by solving (4) with the modified Cholesky factor must encounter a constraint that is not already in the working set.

In order to resolve indefiniteness in this way, we must ensure that the projected Hessian is positive-definite at the first iterate in the QP phase. Given the n by n projected Hessian, a step-wise Cholesky factorization is performed with symmetric interchanges (and corresponding rearrangement of the columns of Z), terminating if the next step would cause the matrix to become indefinite. This determines the largest possible positive-definite principal sub-matrix of the (permuted) projected Hessian. If n steps of the Cholesky factorization have been successfully completed, the relevant projected Hessian is an n by n positive-definite matrix ZHZ, where Z comprises the first n columns of Z. The quadratic function will subsequently be minimized within subspaces of reduced dimension until the full projected Hessian is positive-definite.

If a linear program is being solved and there are fewer general constraints than variables, the method moves from one vertex to another while minimizing the objective function. When necessary, an initial vertex is defined by temporarily fixing some of the variables at their initial values.

Several strategies are used to control ill-conditioning in the working set. One such strategy is associated with the FEATOL array. Allowing the jth constraint to be violated by as much as FEATUL(j) often provides a choice of constraints that could be added to the working set. When a choice exists, the decision is based on the conditioning of the working set. Negative steps are occasionally permitted, since x may violate the constraint to be added.

4. References
5. Parameters

1: ITMAX -- INTEGER
   Input
   On entry: an upper bound on the number of iterations to be
   taken during the LP phase or the QP phase. If ITMAX is not
   positive, then the value 50 is used in place of ITMAX.

2: MSG_LVL -- INTEGER
   Input
   On entry: MSG_LVL must indicate the amount of intermediate
   output desired (see Section 5.1 for a description of the
   printed output). All output is written to the current
   advisory message unit (see X04ABF). For MSG_LVL >= 10, each
   level includes the printout for all lower levels.

   Value   Definition
   <0     No printing.
   0     Printing only if an input parameter is incorrect, or
         if the working set is so ill-conditioned that
         subsequent overflow is likely. This setting is
         strongly recommended in preference to MSG_LVL < 0.
   1     The final solution only.
   5     One brief line of output for each constraint
         addition or deletion (no printout of the final
         solution).
   >=10   The final solution and one brief line of output for
         each constraint addition or deletion.
   >=15   At each iteration, X, ISTATE, and the indices of the
         free variables (i.e., the variables not currently
         held on a bound).
   >=20   At each iteration, the Lagrange multiplier estimates
         and the general constraint values.
At each iteration, the diagonal elements of the matrix $T$ associated with the $TQ$ factorization of the working set, and the diagonal elements of the Cholesky factor $R$ of the projected Hessian.

Debug printout.

The arrays CVEC and HESS.

3: $N$ -- INTEGER  
   On entry: the number, $n$, of variables. Constraint: $N \geq 1$.

4: NCLIN -- INTEGER  
   On entry: the number of general linear constraints in the problem. Constraint: $NCLIN \geq 0$.

5: NCTOTL -- INTEGER  
   On entry: the value $(N+NCLIN)$.

6: NROWA -- INTEGER  
   On entry:  
   the first dimension of the array $A$ as declared in the (sub)program from which E04NAF is called.  
   Constraint: $NROWA \geq \max(1,NCLIN)$.

7: NROWH -- INTEGER  
   On entry:  
   the first dimension of the array HESS as declared in the (sub)program from which E04NAF is called.  
   Constraint: $NROWH \geq 1$.

8: NCOLH -- INTEGER  
   On entry:  
   the column dimension of the array HESS as declared in the (sub)program from which E04NAF is called.  
   Constraint: $NCOLH \geq 1$.

9: BIGBND -- DOUBLE PRECISION  
   On entry: $BIGBND$ must denote an 'infinite' component of $l$ and $u$. Any upper bound greater than or equal to $BIGBND$ will be regarded as plus infinity, and a lower bound less than or equal to $-BIGBND$ will be regarded as minus infinity.  
   Constraint: $BIGBND > 0.0$.

10: $A(NROWA,N)$ -- DOUBLE PRECISION array  
    On entry: the leading $NCLIN$ by $n$ part of $A$ must contain the $NCLIN$ general constraints, with the $i$th constraint in the $i$th row of $A$. If $NCLIN = 0$, then $A$ is not referenced.

11: $BL(NCTOTL)$ -- DOUBLE PRECISION array  
    On entry: the lower bounds for all the constraints, in the following order. The first $n$ elements of $BL$ must contain the
lower bounds on the variables. If NCLIN > 0, the next NCLIN elements of BL must contain the lower bounds for the general linear constraints. To specify a non-existent lower bound (i.e., \( l = -\infty \)), the value used must satisfy \( BL(j) \leq -j \) BIGBND. To specify the jth constraint as an equality, the user must set \( BL(j) = BU(j) \). Constraint: \( BL(j) \leq BU(j) \), \( j=1,2,\ldots,NCTOTL \).

12: BU(NCTOTL) -- DOUBLE PRECISION array Input
On entry: the upper bounds for all the constraints, in the following order. The first n elements of BU must contain the upper bounds on the variables. If NCLIN > 0, the next NCLIN elements of BU must contain the upper bounds for the general linear constraints. To specify a non-existent upper bound (i.e., \( u = +\infty \)), the value used must satisfy \( BU(j) \geq j \) BIGBND. To specify the jth constraint as an equality, the user must set \( BU(j) = BL(j) \). Constraint: \( BU(j) \geq BL(j) \), \( j=1,2,\ldots,NCTOTL \).

13: CVEC(N) -- DOUBLE PRECISION array Input
On entry: the coefficients of the linear term of the objective function (the vector c in equation (1)).

14: FEATOL(NCTOTL) -- DOUBLE PRECISION array Input
On entry: a set of positive tolerances that define the maximum permissible absolute violation in each constraint in order for a point to be considered feasible, i.e., if the violation in constraint \( j \) is less than \( FEATOL(j) \), the point is considered to be feasible with respect to the \( j \)th constraint. The ordering of the elements of FEATOL is the same as that described above for BL.

The elements of FEATOL should not be too small and a warning message will be printed on the current advisory message channel if any element of FEATOL is less than the machine precision (see X02AJF(*)). As the elements of FEATOL increase, the algorithm is less likely to encounter difficulties with ill-conditioning and degeneracy. However, larger values of FEATOL(j) mean that constraint j could be violated by a significant amount. It is recommended that FEATOL(j) be set to a value equal to the largest acceptable violation for constraint j. For example, if the data defining the constraints are of order unity and are correct to about 6 decimal digits, it would be appropriate to choose \( FEATOL(j) = 10^{-6} \) for all relevant j. Often the square root of the machine precision is a reasonable choice if the constraint is well scaled.
15: HESS(NROWH,NCOLH) -- DOUBLE PRECISION array Input
On entry: HESS may be used to store the Hessian matrix H of
equation (1) if desired. HESS is accessed only by the
subroutine QPHESS and is not accessed if LP = .TRUE.. Refer
to the specification of QPHESS (below) for further details
of how HESS may be used to pass data to QPHESS.

16: QPHESS -- SUBROUTINE, supplied by the user.
External Procedure
QPHESS must define the product of the Hessian matrix H and a
vector x. The elements of H need not be defined explicitly.
QPHESS is not accessed if LP is set to .TRUE. and in this
case QPHESS may be the dummy routine E04NAN. (E04NAN is
included in the NAG Foundation Library and so need not be
supplied by the user. Its name may be implementation-
dependent: see the Users' Note for your implementation for
details.)

Its specification is:

SUBROUTINE QPHESS (N, NROWH, NCOLH, JTHCOL,
                      HESS, X, HX)
  INTEGER   N, NROWH, NCOLH, JTHCOL
  DOUBLE PRECISION HESS(NROWH,NCOLH), X(N), HX(N)

1: N -- INTEGER Input
   On entry: the number n of variables.

2: NROWH -- INTEGER Input
   On entry: the row dimension of the array HESS.

3: NCOLH -- INTEGER Input
   On entry: the column dimension of the array HESS.

4: JTHCOL -- INTEGER Input
   The input parameter JTHCOL is included to allow
   flexibility for the user in the special situation when
   x is the jth co-ordinate vector (i.e., the jth column of
   the identity matrix). This may be of interest because
   the product Hx is then the jth column of H, which can
   sometimes be computed very efficiently. The user may
code QPHESS to take advantage of this case. On entry:
   if JTHCOL = j, where j>0, HX must contain column JTHCOL
   of H, and hence special code may be included in QPHESS
to test JTHCOL if desired. However, special code is not
   necessary, since the vector x always contains column
   JTHCOL of the identity matrix whenever QPHESS is called
   with JTHCOL > 0.
5: HESS(NROWH,NCOLH) -- DOUBLE PRECISION array  Input
On entry: the Hessian matrix H.

In some cases, it may be desirable to use a one-
dimensional array to transmit data or workspace to
QPHESS; HESS should then be declared with dimension
(NROWH) in the (sub)program from which E04NAF is called
and the parameter NCOLH must be 1.

In other situations, it may be desirable to compute Hx
without accessing HESS - for example, if H is sparse or
has special structure. (This is illustrated in the
subroutine QPHESS1 in the example program in Section 9.)
The parameters HESS, NROWH and NCOLH may then refer to
any convenient array.

When MSG_LVL = 99, the (possibly undefined) contents of
HESS will be printed, except if NROWH and NCOLH are
both 1. Also printed are the results of calling QPHESS
with JTHCOL = 1,2,...,n.

6: X(N) -- DOUBLE PRECISION array  Input
On entry: the vector x.

7: HX(N) -- DOUBLE PRECISION array  Output
On exit: HX must contain the product Hx.
QPHESS must be declared as EXTERNAL in the (sub)program
from which E04NAF is called. Parameters denoted as
Input must not be changed by this procedure.

17: COLD -- LOGICAL  Input
On entry: COLD must indicate whether the user has specified
an initial estimate of the active set of constraints. If
COLD is set to .TRUE., the initial working set is determined
by E04NAF. If COLD is set to .FALSE. (a 'warm start'), the
user must define the ISTATE array which gives the status of
each constraint with respect to the working set. E04NAF will
override the user's specification of ISTATE if necessary, so
that a poor choice of working set will not cause a fatal
error.

The warm start option is particularly useful when E04NAF is
called repeatedly to solve related problems.

18: LP -- LOGICAL  Input
On entry: if LP = .FALSE., E04NAF will solve the specified
quadratic programming problem. If LP = .TRUE., E04NAF will
treat H as zero and solve the resulting linear programming
problem; in this case, the parameters HESS and QPHESS will
not be referenced.
19: ORTHOG -- LOGICAL
    Input
    On entry: ORTHOG must indicate whether orthogonal
    transformations are to be used in computing and updating the
    TQ factorization of the working set
    \[ A \mathbf{Q} = (0 \mathbf{T}), \]
    \[ s \]
    where \( A \) is a sub-matrix of \( A \) and \( T \) is reverse-triangular.
    \[ s \]
    If ORTHOG = .TRUE., the TQ factorization is computed using
    Householder reflections and plane rotations, and the matrix
    \( Q \) is orthogonal. If ORTHOG = .FALSE., stabilized elementary
    transformations are used to maintain the factorization, and
    \( Q \) is not orthogonal. A rule of thumb in making the choice is
    that orthogonal transformations require more work, but
    provide greater numerical stability. Thus, we recommend
    setting ORTHOG to .TRUE. if the problem is reasonably small
    or the active set is ill-conditioned. Otherwise, setting
    ORTHOG to .FALSE. will often lead to a reduction in solution
time with negligible loss of reliability.

20: X(N) -- DOUBLE PRECISION array
    Input/Output
    On entry: an estimate of the solution. In the absence of
    better information all elements of \( X \) may be set to zero. On
    exit: from E04NAF, \( X \) contains the best estimate of the
    solution.

21: ISTATE(NCTOTL) -- INTEGER array
    Input/Output
    On entry: with COLD as .FALSE., ISTATE must indicate the
    status of every constraint with respect to the working set.
    The ordering of ISTATE is as follows; the first \( n \) elements
    of ISTATE refer to the upper and lower bounds on the
    variables and elements \( n+1 \) through \( n + NCLIN \) refer to the
    upper and lower bounds on \( Ax \). The significance of each
    possible value of ISTATE(j) is as follows:
    
    \[
    \begin{array}{l}
    \text{ISTATE(j)} \quad \text{Meaning} \\
    -2 \quad \text{The constraint violates its lower bound by more} \\
        \text{than FEATOL(j). This value of ISTATE cannot occur} \\
        \text{after a feasible point has been found.} \\
    -1 \quad \text{The constraint violates its upper bound by more} \\
        \text{than FEATOL(j). This value of ISTATE cannot occur} \\
        \text{after a feasible point has been found.} \\
    0 \quad \text{The constraint is not in the working set. Usually,} \\
        \text{this means that the constraint lies strictly} \\
        \text{between its bounds.} \\
    1 \quad \text{This inequality constraint is included in the}
    \end{array}
    \]
working set at its lower bound. The value of the constraint is within FEATOL(j) of its lower bound.

2 This inequality constraint is included in the working set at its upper bound. The value of the constraint is within FEATOL(j) of its upper bound.

3 The constraint is included in the working set as an equality. This value of ISTATE can occur only when BL(j) = BU(j). The corresponding constraint is within FEATOL(j) of its required value.

If COLD = .TRUE., ISTATE need not be set by the user. However, when COLD = .FALSE., every element of ISTATE must be set to one of the values given above to define a suggested initial working set (which will be changed by E04NAF if necessary). The most likely values are:

ISTATE(j) Meaning

0 The corresponding constraint should not be in the initial working set.
1 The constraint should be in the initial working set at its lower bound.
2 The constraint should be in the initial working set at its upper bound.
3 The constraint should be in the initial working set as an equality. This value must not be specified unless BL(j) = BU(j). The values 1, 2 or 3 all have the same effect when BL(j) = BU(j).

Note that if E04NAF has been called previously with the same values of N and NCLIN, ISTATE already contains satisfactory values. On exit: when E04NAF exits with IFAIL set to 0, 1 or 3, the values in the array ISTATE indicate the status of the constraints in the active set at the solution. Otherwise, ISTATE indicates the composition of the working set at the final iterate.

22: ITER -- INTEGER Output
On exit: the number of iterations performed in either the LP phase or the QP phase, whichever was last entered.

Note that ITER is reset to zero after the LP phase.

23: OBJ -- DOUBLE PRECISION Output
On exit: the value of the quadratic objective function at x if x is feasible (IFAIL <= 5), or the sum of infeasibilities at x otherwise (6 <= IFAIL <= 8).
24: CLAMDA(NCTOTL) -- DOUBLE PRECISION array
   Output
   On exit: the values of the Lagrange multiplier for each
   constraint with respect to the current working set. The
   ordering of CLAMDA is as follows; the first n components
   contain the multipliers for the bound constraints on the
   variables, and the remaining components contain the
   multipliers for the general linear constraints. If ISTATE(j)
   = 0 (i.e., constraint j is not in the working set), CLAMDA(j)
   is zero. If x is optimal and ISTATE(j) = 1, CLAMDA(j) should
   be non-negative; if ISTATE(j) = 2, CLAMDA(j) should be non-
   positive.

25: IWORK(LIWORK) -- INTEGER array
   Workspace

26: LIWORK -- INTEGER
   Input
   On entry:
   the dimension of the array IWORK as declared in the
   (sub)program from which E04NAF is called.
   Constraint: LIWORK>=2*N.

27: WORK(LWORK) -- DOUBLE PRECISION array
   Workspace

28: LWORK -- INTEGER
   Input
   On entry:
   the dimension of the array WORK as declared in the
   (sub)program from which E04NAF is called.
   Constraint if LP = .FALSE. or NCLIN >= N then
   nts: 2
   LWORK>=2*N +4*N*NCLIN+NROWA.
   if LP = .TRUE. and NCLIN < N then
   2
   LWORK>=2*(NCLIN+1) +4*N+2*NCLIN+NROWA.
   If MSGLVL > 0, the amount of workspace provided and the
   amount of workspace required are output on the current
   advisory message unit (as defined by X04ABF). As an
   alternative to computing LWORK from the formula given above,
   the user may prefer to obtain an appropriate value from the
   output of a preliminary run with a positive value of MSGLVL
   and LWORK set to 1 (E04NAF will then terminate with IFAIL =
   9).

29: IFAIL -- INTEGER
   Input/Output
   On entry: IFAIL must be set to 0, -1 or 1. Users who are
   unfamiliar with this parameter should refer to the Essential
   Introduction for details.
   On exit: IFAIL = 0 unless the routine detects an error or
   gives a warning (see Section 6).
For this routine, because the values of output parameters may be useful even if IFAIL /\neq 0 on exit, users are recommended to set IFAIL to -1 before entry. It is then essential to test the value of IFAIL on exit. To suppress the output of an error message when soft failure occurs, set IFAIL to 1.

IFAIL contains zero on exit if x is a strong local minimum, i.e., the projected gradient is negligible, the Lagrange multipliers are optimal, and the projected Hessian is positive-definite. In some cases, a zero value of IFAIL means that x is a global minimum (e.g. when the Hessian matrix is positive-definite).

5.1. Description of the Printed Output

When MSGlvl \geq 5, a line of output is produced for every change in the working set (thus, several lines may be printed during a single iteration).

To aid interpretation of the printed results, we mention the convention for numbering the constraints: indices 1 through to n refer to the bounds on the variables, and when NCLIN > 0 indices n+1 through to n + NCLIN refer to the general constraints. When the status of a constraint changes, the index of the constraint is printed, along with the designation L (lower bound), U (upper bound) or E (equality).

In the LP phase, the printout includes the following:

- **ITN** is the iteration count.
- **JDEL** is the index of the constraint deleted from the working set. If JDEL is zero, no constraint was deleted.
- **JADD** is the index of the constraint added to the working set. If JADD is zero, no constraint was added.
- **STEP** is the step taken along the computed search direction.
- **COND T** is a lower bound on the condition number of the matrix of predicted active constraints.
- **NUMINF** is the number of violated constraints (infeasibilities).
- **SUMINF** is a weighted sum of the magnitudes of the
constraint violations.

\[ LPOBJ \]

is the value of the linear objective function \( c^T x \).
It is printed only if \( LP = .TRUE. \).

During the QP phase, the printout includes the following:

\[ ITN \]

is the iteration count (reset to zero after the LP phase).

\[ JDEL \]

is the index of the constraint deleted from the working set. If \( JDEL \) is zero, no constraint was deleted.

\[ JADD \]

is the index of the constraint added to the working set. If \( JADD \) is zero, no constraint was added.

\[ STEP \]

is the step (alpha) taken along the direction of search (if \( STEP \) is 1.0, the current point is a minimum in the subspace defined by the current working set).

\[ NHESS \]

is the number of calls to subroutine QPHESS.

\[ OBJECTIVE \]

is the value of the quadratic objective function.

\[ NCOLZ \]

is the number of columns of \( Z \) (see Section 3). In general, it is the dimension of the subspace in which the quadratic is currently being minimized.

\[ NORM GFREE \]

is the Euclidean norm of the gradient of the objective function with respect to the free variables, i.e. variables not currently held at a bound (\( NORM GFREE \) is not printed if \( ORTHOG = .FALSE. \)). In some cases, the objective function and gradient are updated rather than recomputed. If so, this entry will be -- to indicate that the gradient with respect to the free variables has not been computed.

\[ NORM QTG \]

is a weighted norm of the gradient of the objective function with respect to the free variables (\( NORM QTG \) is not printed if \( ORTHOG = .TRUE. \)). In some cases, the objective function and gradient are updated rather than recomputed. If so, this entry will be -- to indicate that the gradient with respect to the free variables has
NORM ZTG is the Euclidean norm of the projected gradient (see Section 3).

COND T is a lower bound on the condition number of the matrix of constraints in the working set.

COND ZHZ is a lower bound on the condition number of the projected Hessian matrix.

HESS MOD is the correction added to the diagonal of the projected Hessian to ensure that a satisfactory Cholesky factorization exists (see Section 3). When the projected Hessian is sufficiently positive-definite, HESS MOD will be zero.

When MSG_LVL = 1 or MSG_LVL >= 10, the summary printout at the end of execution of E04NAF includes a listing of the status of every constraint. Note that default names are assigned to all variables and constraints.

The following describes the printout for each variable.

VARBL is the name (V) and index j, j=1,2,...,n, of the variable.

STATE gives the state of the variable (FR if neither bound is in the working set, EQ if a fixed variable, LL if on its lower bound, UL if on its upper bound, TB if held on a temporary bound). If VALUE lies outside the upper or lower bounds by more than FEATOL(j), STATE will be ++ or -- respectively.

VALUE is the value of the variable at the final iteration.

LOWER BOUND is the lower bound specified for the variable.

UPPER BOUND is the upper bound specified for the variable.

LAGR MULT is the value of the Lagrange multiplier for the associated bound constraint. This will be zero if STATE is FR. If x is optimal and STATE is LL, the multiplier should be non-negative; if STATE is UL, the multiplier should be non-positive.

RESIDUAL is the difference between the variable and the nearer of its bounds BL(j) and BU(j).
For each of the general constraints the printout is as above with
refers to the jth element of Ax, except that VARBL is replaced by

LNCON The name (L) and index j, j=1,2,...,NCLIN, of the
constraint.

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

IFAIL= 1
x is a weak local minimum (the projected gradient is
negligible, the Lagrange multipliers are optimal, but the
projected Hessian is only semi-definite). This means that
the solution is not unique.

IFAIL= 2
The solution appears to be unbounded, i.e., the quadratic
function is unbounded below in the feasible region. This
value of IFAIL occurs when a step of infinity would have to
be taken in order to continue the algorithm.

IFAIL= 3
x appears to be a local minimum, but optimality cannot be
verified because some of the Lagrange multipliers are very
small in magnitude.

E04NAF has probably found a solution. However, the presence
of very small Lagrange multipliers means that the predicted
active set may be incorrect, or that x may be only a
constrained stationary point rather than a local minimum.
The method in E04NAF is not guaranteed to find the correct
active set when there are very small multipliers. E04NAF
attempts to delete constraints with zero multipliers, but
this does not necessarily resolve the issue. The
determination of the correct active set is a combinatorial
problem that may require an extremely large amount of time.
The occurrence of small multipliers often (but not always)
indicates that there are redundant constraints.

IFAIL= 4
The iterates of the QP phase could be cycling, since a total
of 50 changes were made to the working set without altering
x.

This value will occur if 50 iterations are performed in the
QP phase without changing x. The user should check the
printed output for a repeated pattern of constraint
deletions and additions. If a sequence of constraint changes
is being repeated, the iterates are probably cycling. (E04NAF does not contain a method that is guaranteed to avoid cycling, which would be combinatorial in nature.) Cycling may occur in two circumstances: at a constrained stationary point where there are some small or zero Lagrange multipliers (see the discussion of IFAIL = 3); or at a point (usually a vertex) where the constraints that are satisfied exactly are nearly linearly dependent. In the latter case, the user has the option of identifying the offending dependent constraints and removing them from the problem, or restarting the run with larger values of FEATOL for nearly dependent constraints. If E04NAF terminates with IFAIL = 4, but no suspicious pattern of constraint changes can be observed, it may be worthwhile to restart with the final x (with or without the warm start option).

IFAIL = 5
The limit of ITMAX iterations was reached in the QP phase before normal termination occurred.

The value of ITMAX may be too small. If the method appears to be making progress (e.g. the objective function is being satisfactorily reduced), increase ITMAX and rerun E04NAF (possibly using the warm start facility to specify the initial working set). If ITMAX is already large, but some of the constraints could be nearly linearly dependent, check the output for a repeated pattern of constraints entering and leaving the working set. (Near-dependencies are often indicated by wide variations in size in the diagonal elements of the T matrix, which will be printed if MSGLVL >= 30.) In this case, the algorithm could be cycling (see the comments for IFAIL = 4).

IFAIL = 6
The LP phase terminated without finding a feasible point, and hence it is not possible to satisfy all the constraints to within the tolerances specified by the FEATOL array. In this case, the final iterate will reveal values for which there will be a feasible point (e.g. a feasible point will exist if the feasibility tolerance for each violated constraint exceeds its RESIDUAL at the final point). The modified problem (with altered values in FEATOL) may then be solved using a warm start.

The user should check that there are no constraint redundancies. If the data for the jth constraint are accurate only to the absolute precision (delta), the user should ensure that the value of FEATOL(j) is greater than (delta). For example, if all elements of A are of order unity and are accurate only to three decimal places, every
component of FEATOL should be at least 10.

IFAIL= 7
The iterates may be cycling during the LP phase; see the comments above under IFAIL = 4.

IFAIL= 8
The limit of ITMAX iterations was reached during the LP phase. See comments above under IFAIL = 5.

IFAIL= 9
An input parameter is invalid.

Overflow
If the printed output before the overflow error contains a warning about serious ill-conditioning in the working set when adding the jth constraint, it may be possible to avoid the difficulty by increasing the magnitude of FEATOL(j) and rerunning the program. If the message recurs even after this change, the offending linearly dependent constraint (with index j) must be removed from the problem. If a warning message did not precede the fatal overflow, the user should contact NAG.

7. Accuracy
The routine implements a numerically stable active set strategy and returns solutions that are as accurate as the condition of the QP problem warrants on the machine.

8. Further Comments
The number of iterations depends upon factors such as the number of variables and the distances of the starting point from the solution. The number of operations performed per iteration is roughly proportional to (NFREE)^2, where NFREE (NFREE<=n) is the number of variables fixed on their upper or lower bounds.

Sensible scaling of the problem is likely to reduce the number of iterations required and make the problem less sensitive to perturbations in the data, thus improving the condition of the QP problem. See the Chapter Introduction and Gill et al [1] for further information and advice.

9. Example

\[
\begin{array}{ccc}
T & 1 & T \\
\end{array}
\]
To minimize the function \( c^T x - x^T H x \), where
2

\[ c = [-0.02, -0.2, -0.2, -0.2, -0.2, 0.04, 0.04] \]

\[
\begin{bmatrix}
2 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 2 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 2 & 2 & 0 & 0 & 0 \\
\end{bmatrix}
\]

\[
H = \begin{bmatrix}
0 & 0 & 2 & 2 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 2 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & -2 & -2 \\
0 & 0 & 0 & 0 & 0 & -2 & -2 \\
\end{bmatrix}
\]

subject to the bounds

Minimize an arbitrary smooth constrained function

— nage.ht —

E04UCF(3NAG) E04UCF E04UCF(3NAG)

E04 -- Minimizing or Maximizing a Function

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

Note for users via the Axiom system: the interface to this routine has been enhanced for use with Axiom and is slightly different to that offered in the standard version of the Foundation Library. 

In
particular, the optional parameters of the NAG routine are now included in the parameter list. These are described in section 5.1.2, below.

1. Purpose

E04UCF is designed to minimize an arbitrary smooth function subject to constraints, which may include simple bounds on the variables, linear constraints and smooth nonlinear constraints. (E04UCF may be used for unconstrained, bound-constrained and linearly constrained optimization.) The user must provide subroutines that define the objective and constraint functions and as many of their first partial derivatives as possible. Unspecified derivatives are approximated by finite differences. All matrices are treated as dense, and hence E04UCF is not intended for large sparse problems.

E04UCF uses a sequential quadratic programming (SQP) algorithm in which the search direction is the solution of a quadratic programming (QP) problem. The algorithm treats bounds, linear constraints and nonlinear constraints separately.

2. Specification

SUBROUTINE E04UCF (N, NCLIN, NCNLN, NROWA, NROWJ, NROWR,

3. Description

E04UCF is designed to solve the nonlinear programming problem --
the minimization of a smooth nonlinear function subject to a set of constraints on the variables. The problem is assumed to be stated in the following form:

\[
\begin{align*}
\text{Minimize} & \quad F(x) \quad \text{subject to} \quad l \leq \{A \cdot x\} \leq u, \\
& \quad \{L\} \leq c(x), \quad \{x\} \in \mathbb{R}^n.
\end{align*}
\]

where \( F(x) \), the objective function, is a nonlinear function, \( A \) is an \( n \times n \) constant matrix, and \( c(x) \) is an \( n \) element vector of nonlinear constraint functions. (The matrix \( A \) and the vector \( c(x) \) may be empty.) The objective function and the constraint functions are assumed to be smooth, i.e., at least twice-continuously differentiable. (The method of E04UCF will usually solve (1) if there are only isolated discontinuities away from the solution.)

This routine is essentially identical to the subroutine SOL/NPSOL described in Gill et al [8].

Note that upper and lower bounds are specified for all the variables and for all the constraints.

An equality constraint can be specified by setting \( l = u \). If certain bounds are not present, the associated elements of \( l \) or \( u \) can be set to special values that will be treated as \(-\infty\) or \(+\infty\).

If there are no nonlinear constraints in (1) and \( F \) is linear or quadratic then one of E04MBF, E04NAF or E04NCF(*) will generally be more efficient. If the problem is large and sparse the MINOS package (see Murtagh and Saunders [13]) should be used, since E04UCF treats all matrices as dense.

The user must supply an initial estimate of the solution to (1), together with subroutines that define \( F(x) \), \( c(x) \) and as many first partial derivatives as possible; unspecified derivatives are approximated by finite differences.

The objective function is defined by subroutine OBJFUN, and the nonlinear constraints are defined by subroutine CONFUN. On every call, these subroutines must return appropriate values of the objective and nonlinear constraints. The user should also provide the available partial derivatives. Any unspecified derivatives are approximated by finite differences; see Section 5.1 for a
discussion of the optional parameter Derivative Level. Just before either OBJFUN or CONFUN is called, each element of the current gradient array OBJGRD or CJAC is initialised to a special value. On exit, any element that retains the value is estimated by finite differences. Note that if there are nonlinear constraints, then the first call to CONFUN will precede the first call to OBJFUN.

For maximum reliability, it is preferable for the user to provide all partial derivatives (see Chapter 8 of Gill et al [10], for a detailed discussion). If all gradients cannot be provided, it is similarly advisable to provide as many as possible. While developing the subroutines OBJFUN and CONFUN, the optional parameter Verify (see Section 5.1) should be used to check the calculation of any known gradients.

E04UCF implements a sequential quadratic programming (SQP) method. The document for E04NCF(*) should be consulted in conjunction with this document.

In the rest of this section we briefly summarize the main features of the method of E04UCF. Where possible, explicit reference is made to the names of variables that are parameters of subroutines E04UCF or appear in the printed output (see Section 5.2).

At a solution of (1), some of the constraints will be active, i.e., satisfied exactly. An active simple bound constraint implies that the corresponding variable is fixed at its bound, and hence the variables are partitioned into fixed and free variables. Let C denote the m by n matrix of gradients of the active general linear and nonlinear constraints. The number of fixed variables will be denoted by n , with n (n =n-n ) the number of free variables. The subscripts 'FX' and 'FR' on a vector or matrix will denote the vector or matrix composed of the components corresponding to fixed or free variables.

A point x is a first-order Kuhn-Tucker point for (1) (see, e.g., Powell [14]) if the following conditions hold:

(i) x is feasible;

(ii) there exist vectors (xi) and (lambda) (the Lagrange multiplier vectors for the bound and general constraints) such that

\[ g = C (lambda) + (xi), \]  

where g is the gradient of F evaluated at x, and (xi) = 0 if j

\[ j \]
the jth variable is free.

(iii) The Lagrange multiplier corresponding to an inequality constraint active at its lower bound must be non-negative, and non-positive for an inequality constraint active at its upper bound.

Let Z denote a matrix whose columns form a basis for the set of vectors orthogonal to the rows of C; i.e., \( C Z = 0 \). An equivalent statement of the condition (2) in terms of Z is

\[
T Z g = 0.
\]

The vector \( Z g \) is termed the projected gradient of F at x.

Certain additional conditions must be satisfied in order for a first-order Kuhn-Tucker point to be a solution of (1) (see, e.g., Powell [14]).

The method of E04UCF is a sequential quadratic programming (SQP) method. For an overview of SQP methods, see, for example, Fletcher [5], Gill et al [10] and Powell [15].

The basic structure of E04UCF involves major and minor iterations. The major iterations generate a sequence of iterates \( \{ x_k \} \) that converge to \( x \), a first-order Kuhn-Tucker point of (1).

At a typical major iteration, the new iterate \( x \) is defined by

\[
x = x + \alpha p
\]

where \( x \) is the current iterate, the non-negative scalar (\( \alpha \)) is the step length, and p is the search direction. (For simplicity, we shall always consider a typical iteration and avoid reference to the index of the iteration.) Also associated with each major iteration are estimates of the Lagrange multipliers and a prediction of the active set.

The search direction \( p \) in (3) is the solution of a quadratic programming subproblem of the form

\[
\begin{align*}
\text{Minimize} & \quad g^T p + \frac{1}{2} p^T H p, \\
\text{subject to} & \quad 1 \leq \langle A, p \rangle \leq u,
\end{align*}
\]
where $g$ is the gradient of $F$ at $x$, the matrix $H$ is a positive-definite quasi-Newton approximation to the Hessian of the Lagrangian function (see Section 8.3), and $A$ is the Jacobian matrix of $c$ evaluated at $x$. (Finite-difference estimates may be used for $g$ and $A$; see the optional parameter Derivative Level in Section 5.1.) Let $l$ in (1) be partitioned into three sections: $l_B$, $l_L$, and $l_N$, corresponding to the bound, linear and nonlinear constraints. The vector $l$ in (4) is similarly partitioned, and is defined as

\[
\begin{align*}
\bar{l}_B &= l_B - x_B, \\
\bar{l}_L &= l_L - A_L x_L, \\
\bar{l}_N &= l_N - c_N,
\end{align*}
\]

where $c$ is the vector of nonlinear constraints evaluated at $x$. The vector $u$ is defined in an analogous fashion.

The estimated Lagrange multipliers at each major iteration are the Lagrange multipliers from the subproblem (4) (and similarly for the predicted active set). (The numbers of bounds, general linear and nonlinear constraints in the QP active set are the quantities $Bnd$, $Lin$ and $Nln$ in the printed output of E04UCF.) In E04UCF, (4) is solved using E04NCF(*). Since solving a quadratic program as an iterative procedure, the minor iterations of E04UCF are the iterations of E04NCF(*). (More details about solving the subproblem are given in Section 8.1.)

Certain matrices associated with the QP subproblem are relevant in the major iterations. Let the subscripts 'FX' and 'FR' refer to the predicted fixed and free variables, and let $C$ denote the $m$ by $n$ matrix of gradients of the general linear and nonlinear constraints in the predicted active set. First, we have available the $TQ$ factorization of $C$:

\[
C_{FR} Q_{FR} = (0 \ T), \quad (5)
\]

where $T$ is a nonsingular $m$ by $m$ reverse-triangular matrix (i.e., $t_{ij} = 0$ if $i+j<m$), and the non-singular $n$ by $n$ matrix $Q$ is

\[
\begin{align*}
Q_{FR} &= Q_{FR} Q_{FR} Q_{FR}.
\end{align*}
\]
the product of orthogonal transformations (see Gill et al [6]).
Second, we have the upper-triangular Cholesky factor $R$ of the transformed and re-ordered Hessian matrix

$$
R \, R^T = Q \, H \, Q,
$$
(6)

where $H$ is the Hessian $H$ with rows and columns permuted so that the free variables are first, and $Q$ is the $n \times n$ matrix

$$
Q = (I, \, \frac{F}{X})
$$
(7)

with $I$ the identity matrix of order $n$. If the columns of $Q$

$$
Q = (Z, \, Y),
$$
FR

are partitioned so that

$$
Z \, z = (Z, \, Y),
$$
FR

the $n \times (n - n - m)$ columns of $Z$ form a basis for the null space of

$$
C.
$$
FR

The matrix $Z$ is used to compute the projected gradient $Z \, g$

$$
Z \, g = (Z, \, Y),
$$
FR

at the current iterate. (The values $Nz$, Norm $Gf$ and Norm $Gz$

$$
Nz = (Z, \, Y),
$$
FR

printed by E04UCF give $n$ and the norms of $g$ and $Z \, g$.)

A theoretical characteristic of SQP methods is that the predicted active set from the QP subproblem (4) is identical to the correct active set in a neighbourhood of $x$. In E04UCF, this feature is exploited by using the QP active set from the previous iteration as a prediction of the active set for the next QP subproblem, which leads in practice to optimality of the subproblems in only one iteration as the solution is approached. Separate treatment of bound and linear constraints in E04UCF also saves computation in factorizing $C$ and $H$.

Once $p$ has been computed, the major iteration proceeds by determining a step length (alpha) that produces a 'sufficient decrease' in an augmented Lagrangian merit function (see Section 8.2). Finally, the approximation to the transformed Hessian
matrix $H$ is updated using a modified BFGS quasi-Newton update $Q$
(see Section 8.3) to incorporate new curvature information obtained in the move from $x$ to $x$.

On entry to E04UCF, an iterative procedure from E04NCF(*) is executed, starting with the user-provided initial point, to find a point that is feasible with respect to the bounds and linear constraints (using the tolerance specified by Linear Feasibility Tolerance see Section 5.1). If no feasible point exists for the bound and linear constraints, (1) has no solution and E04UCF terminates. Otherwise, the problem functions will thereafter be evaluated only at points that are feasible with respect to the bounds and linear constraints. The only exception involves variables whose bounds differ by an amount comparable to the finite-difference interval (see the discussion of Difference Interval in Section 5.1). In contrast to the bounds and linear constraints, it must be emphasised that the nonlinear constraints will not generally be satisfied until an optimal point is reached.

Facilities are provided to check whether the user-provided gradients appear to be correct (see the optional parameter Verify in Section 5.1). In general, the check is provided at the first point that is feasible with respect to the linear constraints and bounds. However, the user may request that the check be performed at the initial point.

In summary, the method of E04UCF first determines a point that satisfies the bound and linear constraints. Thereafter, each iteration includes:

(a) the solution of a quadratic programming subproblem;
(b) a linesearch with an augmented Lagrangian merit function; and
(c) a quasi-Newton update of the approximate Hessian of the Lagrangian function.

These three procedures are described in more detail in Section 8.

4. References

CHAPTER 22. NAG LIBRARY ROUTINES

5. Parameters

1: \( N \) -- INTEGER Input
On entry: the number, \( n \), of variables in the problem.
Constraint: \( N > 0 \).

2: \( NCLIN \) -- INTEGER Input
On entry: the number, \( n \), of general linear constraints in the problem. Constraint: \( NCLIN \geq 0 \).

3: \( NCNLN \) -- INTEGER Input
On entry: the number, \( n \), of nonlinear constraints in the problem. Constraint: \( NCNLN \geq 0 \).

4: \( NROWA \) -- INTEGER Input
On entry: the first dimension of the array A as declared in the (sub)program from which E04UCF is called.
Constraint: \( NROWA \geq \max(1,NCLIN) \).

5: \( NROWJ \) -- INTEGER Input
On entry: the first dimension of the array CJAC as declared in the (sub)program from which E04UCF is called.
Constraint: \( NROWJ \geq \max(1,NCNLN) \).

6: \( NROWR \) -- INTEGER Input
On entry: the first dimension of the array R as declared in the (sub)program from which E04UCF is called.
Constraint: \( NROWR \geq N \).

7: \( A(NROWA,*) \) -- DOUBLE PRECISION array Input
The second dimension of the array A must be \( \geq N \) for \( NCLIN > 0 \). On entry: the ith row of the array A must contain the ith row of the matrix A of general linear constraints in (1).
That is, the ith row contains the coefficients of the ith general linear constraint, for \( i = 1,2,\ldots,NCLIN \).
If NCLIN = 0 then the array A is not referenced.

8: BL(N+NCLIN+NCNLN) -- DOUBLE PRECISION array Input
On entry: the lower bounds for all the constraints, in the
following order. The first n elements of BL must contain the
lower bounds on the variables. If NCLIN > 0, the next n
L
elements of BL must contain the lower bounds on the general
linear constraints. If NCNLN > 0, the next n elements of BL
N
must contain the lower bounds for the nonlinear constraints.
To specify a non-existent lower bound (i.e., l = -infty), the
j
value used must satisfy BL(j) <= -BIGBND, where BIGBND is the
value of the optional parameter Infinite Bound Size whose
default value is 10 (see Section 5.1). To specify the jth
constraint as an equality, the user must set BL(j) = BU(j) =
(beta), say, where |(beta)| < BIGBND. Constraint: BL(j) <= BU(
j), for j=1,2,...,N+NCLIN+NCNLN.

9: BU(N+NCLIN+NCNLN) -- DOUBLE PRECISION array Input
On entry: the upper bounds for all the constraints in the
following order. The first n elements of BU must contain the
upper bounds on the variables. If NCLIN > 0, the next n
L
elements of BU must contain the upper bounds on the general
linear constraints. If NCNLN > 0, the next n elements of BU
N
must contain the upper bounds for the nonlinear constraints.
To specify a non-existent upper bound (i.e., u = +infty), the
j
value used must satisfy BU(j) >= BIGBND, where BIGBND is the
value of the optional parameter Infinite Bound Size, whose
default value is 10 (see Section 5.1). To specify the jth
constraint as an equality, the user must set BU(j) = BL(j) =
(beta), say, where |(beta)| < BIGBND. Constraint: BU(j) >=
BL(j), for j=1,2,...,N+NCLIN+NCNLN.

10: CONFUN -- SUBROUTINE, supplied by the user.
External Procedure
CONFUN must calculate the vector c(x) of nonlinear
constraint functions and (optionally) its Jacobian for a
specified n element vector x. If there are no nonlinear
constraints (NCNLN=0), CONFUN will never be called by E04UCF
and CONFUN may be the dummy routine E04UDM. (E04UDM is
included in the NAG Foundation Library and so need not be
supplied by the user. Its name may be implementation-
dependent: see the Users' Note for your implementation for
details.) If there are nonlinear constraints, the first call to CONFUN will occur before the first call to OBJFUN.

Its specification is:

```fortran
SUBROUTINE CONFUN (MODE, NCNLN, N, NROWJ, NEEDC, 1
X, C, CJAC, NSTATE, IUSER, 2
USER)
INTEGER MODE, NCNLN, N, NROWJ, NEEDC 1
(NCNLN), NSTATE, IUSER(*)
DOUBLE PRECISION X(N), C(NCNLN), CJAC(NROWJ,N), 1
USER(*)
```

1: **MODE** -- INTEGER  
   Input/Output  
   On entry: MODE indicates the values that must be assigned during each call of CONFUN. MODE will always have the value 2 if all elements of the Jacobian are available, i.e., if Derivative Level is either 2 or 3 (see Section 5.1). If some elements of CJAC are unspecified, E04UCF will call CONFUN with MODE = 0, 1, or 2:

   If MODE = 2, only the elements of C corresponding to positive values of NEEDC must be set (and similarly for the available components of the rows of CJAC).

   If MODE = 1, the available components of the rows of CJAC corresponding to positive values in NEEDC must be set. Other rows of CJAC and the array C will be ignored.

   If MODE = 0, the components of C corresponding to positive values in NEEDC must be set. Other components and the array CJAC are ignored. On exit: MODE may be set to a negative value if the user wishes to terminate the solution to the current problem. If MODE is negative on exit from CONFUN then E04UCF will terminate with IFAIL set to MODE.

2: **NCNLN** -- INTEGER  
   Input  
   On entry: the number, n, of nonlinear constraints.

3: **N** -- INTEGER  
   Input  
   On entry: the number, n, of variables.

4: **NROWJ** -- INTEGER  
   Input  
   On entry: the first dimension of the array CJAC.

5: **NEEDC(NCNLN)** -- INTEGER array  
   Input
On entry: the indices of the elements of C or CJAC that must be evaluated by CONFUN. If NEEDC(i)>0 then the ith element of C and/or the ith row of CJAC (see parameter MODE above) must be evaluated at x.

6: X(N) -- DOUBLE PRECISION array  
On entry: the vector x of variables at which the constraint functions are to be evaluated.

7: C(NCNLN) -- DOUBLE PRECISION array  
On exit: if NEEDC(i)>0 and MODE = 0 or 2, C(i) must contain the value of the ith constraint at x. The remaining components of C, corresponding to the non-positive elements of NEEDC, are ignored.

8: CJAC(NROWJ,N) -- DOUBLE PRECISION array  
On exit: if NEEDC(i)>0 and MODE = 1 or 2, the ith row of CJAC must contain the available components of the vector \( (\nabla c)_i \) given by
\[
( \begin{array}{ccc}
  \frac{\partial c_i}{\partial x_1} & \frac{\partial c_i}{\partial x_2} & \cdots & \frac{\partial c_i}{\partial x_n} \\
  \end{array} )
\]
where \( \frac{\partial c_i}{\partial x_j} \) is the partial derivative of the ith constraint with respect to the jth variable, evaluated at the point x. See also the parameter NSTATE below. The remaining rows of CJAC, corresponding to non-positive elements of NEEDC, are ignored.

If all constraint gradients (Jacobian elements) are known (i.e., Derivative Level = 2 or 3; see Section 5.1) any constant elements may be assigned to CJAC one time only at the start of the optimization. An element of CJAC that is not subsequently assigned in CONFUN will retain its initial value throughout. Constant elements may be loaded into CJAC either before the call to E04UCF or during the first call to CONFUN (signalled by the value NSTATE = 1). The ability to preload constants is useful when many Jacobian elements are identically zero, in which case CJAC may be initialised to zero and non-zero elements may be reset by CONFUN.

Note that constant non-zero elements do affect the values of the constraints. Thus, if CJAC(i,j) is set to
a constant value, it need not be reset in subsequent calls to CONFUN, but the value CJAC(i,j)*X(j) must nonetheless be added to C(i).

It must be emphasized that, if Derivative Level < 2, unassigned elements of CJAC are not treated as constant; they are estimated by finite differences, at non-trivial expense. If the user does not supply a value for Difference Interval (see Section 5.1), an interval for each component of x is computed automatically at the start of the optimization. The automatic procedure can usually identify constant elements of CJAC, which are then computed once only by finite differences.

9: NSTATE -- INTEGER Input
On entry: if NSTATE = 1 then E04UCF is calling CONFUN for the first time. This parameter setting allows the user to save computation time if certain data must be read or calculated only once.

10: IUSER(*) -- INTEGER array User Workspace

11: USER(*) -- DOUBLE PRECISION array User Workspace
CONFUN is called from E04UCF with the parameters IUSER and USER as supplied to E04UCF. The user is free to use the arrays IUSER and USER to supply information to CONFUN as an alternative to using COMMON. CONFUN must be declared as EXTERNAL in the (sub)program from which E04UCF is called. Parameters denoted as Input must not be changed by this procedure.

11: OBJFUN -- SUBROUTINE, supplied by the user.
External Procedure
OBJFUN must calculate the objective function F(x) and (optionally) the gradient g(x) for a specified n element vector x.

Its specification is:

```
SUBROUTINE OBJFUN (MODE, N, X, OBJF, OBJGRD, NSTATE, IUSER, USER)
  INTEGER MODE, N, NSTATE, IUSER(*)
  DOUBLE PRECISION X(N), OBJF, OBJGRD(N), USER(*)
```

1: MODE -- INTEGER Input/Output
On entry: MODE indicates the values that must be assigned during each call of OBJFUN.

MODE will always have the value 2 if all components of
the objective gradient are specified by the user, i.e.,
if Derivative Level is either 1 or 3. If some gradient
elements are unspecified, E04UCF will call OBJFUN with
MODE = 0, 1 or 2.

If MODE = 2, compute OBJF and the available
components of OBJGRD.

If MODE = 1, compute all available components of
OBJGRD; OBJF is not required.

If MODE = 0, only OBJF needs to be computed;
OBJGRD is ignored.

On exit: MODE may be set to a negative value if the
user wishes to terminate the solution to the current
problem. If MODE is negative on exit from OBJFUN, then
E04UCF will terminate with IFAIL set to MODE.

2: N -- INTEGER Input
On entry: the number, n, of variables.

3: X(N) -- DOUBLE PRECISION array Input
On entry: the vector x of variables at which the
objective function is to be evaluated.

4: OBJF -- DOUBLE PRECISION Output
On exit: if MODE = 0 or 2, OBJF must be set to the
value of the objective function at x.

5: OBJGRD(N) -- DOUBLE PRECISION array Output
On exit: if MODE = 1 or 2, OBJGRD must return the
available components of the gradient evaluated at x.

6: NSTATE -- INTEGER Input
On entry: if NSTATE = 1 then E04UCF is calling OBJFUN
for the first time. This parameter setting allows the
user to save computation time if certain data must be
read or calculated only once.

7: IUSER(*) -- INTEGER array User Workspace

8: USER(*) -- DOUBLE PRECISION array User Workspace
OBJFUN is called from E04UCF with the parameters IUSER
and USER as supplied to E04UCF. The user is free to use
the arrays IUSER and USER to supply information to
OBJFUN as an alternative to using COMMON.
OBJFUN must be declared as EXTERNAL in the (sub)program
from which E04UCF is called. Parameters denoted as
Input must not be changed by this procedure.

12: ITER -- INTEGER Output
On exit: the number of iterations performed.

13: ISTATE(N+NCLIN+NCNLN) -- INTEGER array Input/Output

On entry: ISTATE need not be initialised if E04UCF is called with (the default) Cold Start option. The ordering of ISTATE is as follows. The first n elements of ISTATE refer to the upper and lower bounds on the variables, elements n+1 through n+n refer to the upper and lower bounds on A x, and elements n+n +1 through n+n +n refer to the upper and lower bounds on c(x). When a Warm Start option is chosen, the elements of ISTATE corresponding to the bounds and linear constraints define the initial working set for the procedure that finds a feasible point for the linear constraints and bounds. The active set at the conclusion of this procedure and the elements of ISTATE corresponding to nonlinear constraints then define the initial working set for the first QP subproblem. Possible values for ISTATE(j) are:

ISTATE(j) Meaning

0 The corresponding constraint is not in the initial QP working set.

1 This inequality constraint should be in the working set at its lower bound.

2 This inequality constraint should be in the working set at its upper bound.

3 This equality constraint should be in the initial working set. This value must not be specified unless BL(j) = BU(j). The values 1, 2 or 3 all have the same effect when BL(j) = BU(j).

Note that if E04UCF has been called previously with the same values of N, NCLIN and NCNLN, ISTATE already contains satisfactory values. If necessary, E04UCF will override the user’s specification of ISTATE so that a poor choice will not cause the algorithm to fail. On exit: with IFAIL = 0 or 1, the values in the array ISTATE correspond to the active set of the final QP subproblem, and are a prediction of the status of the constraints at the solution of the problem. Otherwise, ISTATE indicates the composition of the QP working set at the final iterate. The significance of each possible value of ISTATE(j) is as follows:

-2 This constraint violates its lower bound by more than the appropriate feasibility tolerance (see the optional parameters LinearFeasibility Tolerance and Nonlinear Feasibility Tolerance in
22.4. NAGE.HT

Section 5.1). This value can occur only when no feasible point can be found for a QP subproblem.

-1 This constraint violates its upper bound by more than the appropriate feasibility tolerance (see the optional parameters Linearar Feasibility Tolerance and Nonlinear Feasibility Tolerance in Section 5.1). This value can occur only when no feasible point can be found for a QP subproblem.

0 The constraint is satisfied to within the feasibility tolerance, but is not in the working set.

1 This inequality constraint is included in the QP working set at its upper bound.

2 This inequality constraint is included in the QP working set at its upper bound.

3 This constraint is included in the QP working set as an equality. This value of ISTATE can occur only when BL(j) = BU(j).

14: C(*) -- DOUBLE PRECISION array Output
Note: the dimension of the array C must be at least max(1,NCNLN).
On exit: if NCNLN > 0, C(i) contains the value of the ith nonlinear constraint function c at the final iterate, for i = 1,2,...,NCNLN. If NCNLN = 0, then the array C is not referenced.

15: CJAC(NROWJ,*) -- DOUBLE PRECISION array Input/Output
Note: the second dimension of the array CJAC must be at least N for NCNLN >0 and 1 otherwise. On entry: in general, CJAC need not be initialised before the call to E04UCF. However, if Derivative Level = 3, the user may optionally set the constant elements of CJAC (see parameter NSTATE in the description of CONFUN). Such constant elements need not be re-assigned on subsequent calls to CONFUN. If NCNLN = 0, then the array CJAC is not referenced. On exit: if NCNLN > 0, CJAC contains the Jacobian matrix of the nonlinear constraint functions at the final iterate, i.e., CJAC(i,j) contains the partial derivative of the ith constraint function with respect to the jth variable, for i=1,2,...,NCNLN; j = 1,2,...,N. (See the discussion of parameter CJAC under CONFUN.)

16: CLAMDA(N+NCLIN+NCNLN) -- DOUBLE PRECISION array Input/Output
On entry: CLAMDA need not be initialised if E04UCF is called with the (default) Cold Start option. With the Warm Start option, CLAMDA must contain a multiplier estimate for each nonlinear constraint with a sign that matches the status of the constraint specified by the ISTATE array (as above). The ordering of CLAMDA is as follows; the first n elements contain the multipliers for the bound constraints on the variables, elements n+1 through n+n contain the multipliers for the general linear constraints, and elements n+n+1 through n+n+n contain the multipliers for the nonlinear constraints. If the jth constraint is defined as ‘inactive’ by the initial value of the ISTATE array, CLAMDA(j) should be zero; if the jth constraint is an inequality active at its lower bound, CLAMDA(j) should be non-negative; if the jth constraint is an inequality active at its upper bound, CLAMDA(j) should be non-positive. On exit: the values of the QP multipliers from the last QP subproblem.

17: OBJF -- DOUBLE PRECISION
On exit: the value of the objective function, F(x), at the final iterate.

18: OBJGRD(N) -- DOUBLE PRECISION array
On exit: the gradient (or its finite-difference approximation) of the objective function at the final iterate.

19: R(NROWR,N) -- DOUBLE PRECISION array
On entry: R need not be initialised if E04UCF is called with a Cold Start option (the default), and will be taken as the identity. With a Warm Start R must contain the upper-triangular Cholesky factor R of the initial approximation of the Hessian of the Lagrangian function, with the variables in the natural order. Elements not in the upper-triangular part of R are assumed to be zero and need not be assigned. On exit: if Hessian = No, (the default; see Section 5.1), R contains the upper-triangular Cholesky factor R of the transformed and re-ordered Hessian of the Lagrangian at x (see (6) in Section 3). If Hessian = Yes, R contains the upper-triangular Cholesky factor R of H, the approximate (untransformed) Hessian of the Lagrangian, with the variables in the natural order.

20: X(N) -- DOUBLE PRECISION array

On entry: an initial estimate of the solution. On exit: the final estimate of the solution.

21: IWORK(LIWORK) -- INTEGER array Workspace

22: LIWORK -- INTEGER Input
On entry: the dimension of the array IWORK as declared in the (sub)program from which E04UCF is called.
Constraint: LIWORK >= 3*N + NCLIN + 2*NCNLN.

23: WORK(LWORK) -- DOUBLE PRECISION array Workspace

24: LWORK -- INTEGER Input
On entry: the dimension of the array WORK as declared in the (sub)program from which E04UCF is called.
Constraints:
if NCLIN = NCNLN = 0 then
  LWORK >= 20*N
if NCNLN = 0 and NCLIN > 0 then
  LWORK >= 2*N + 20*N + 11*NCLIN
if NCNLN > 0 and NCLIN >= 0 then
  LWORK >= 2*N + N*NCLIN + 20*N + NCNLN + 20*N + 11*NCLIN + 21*NCNLN

If Major Print Level > 0, the required amounts of workspace are output on the current advisory message channel (see X04ABF). As an alternative to computing LIWORK and LWORK from the formulas given above, the user may prefer to obtain appropriate values from the output of a preliminary run with a positive value of Major Print Level and LIWORK and LWORK set to 1. (E04UCF will then terminate with IFAIL = 9.)

25: IUSER(*) -- INTEGER array User Workspace
Note: the dimension of the array IUSER must be at least 1. IUSER is not used by E04UCF, but is passed directly to routines CONFUN and OBJFUN and may be used to pass information to those routines.

26: USER(*) -- DOUBLE PRECISION array User Workspace
Note: the dimension of the array USER must be at least 1. USER is not used by E04UCF, but is passed directly to routines CONFUN and OBJFUN and may be used to pass information to those routines.

27: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. Users who are unfamiliar with this parameter should refer to the Essential Introduction for details.

On exit: IFAIL = 0 unless the routine detects an error or gives a warning (see Section 6).

For this routine, because the values of output parameters may be useful even if IFAIL /=0 on exit, users are recommended to set IFAIL to -1 before entry. It is then essential to test the value of IFAIL on exit.

E04UCF returns with IFAIL = 0 if the iterates have converged to a point x that satisfies the first-order Kuhn-Tucker conditions to the accuracy requested by the optional parameter Optimality Tolerance (see Section 5.1), i.e., the projected gradient and active constraint residuals are negligible at x.

The user should check whether the following four conditions are satisfied:

(i) the final value of Norm Gz is significantly less than that at the starting point;

(ii) during the final major iterations, the values of Step and ItQp are both one;

(iii) the last few values of both Norm Gz and Norm C become small at a fast linear rate;

(iv) Cond Hz is small.

If all these conditions hold, x is almost certainly a local minimum of (1). (See Section 9 for a specific example.)

5.1. Optional Input Parameters

Several optional parameters in E04UCF define choices in the behaviour of the routine. In order to reduce the number of formal parameters of E04UCF these optional parameters have associated default values (see Section 5.1.3) that are appropriate for most problems. Therefore the user need only specify those optional parameters whose values are to be different from their default values.

The remainder of this section can be skipped by users who wish to use the default values for all optional parameters. A complete list of optional parameters and their default values is given in Section 5.1.3

5.1.1. Specification of the optional parameters
Optional parameters may be specified by calling one, or both, of E04UDF and E04UEF prior to a call to E04UCF.

E04UDF reads options from an external options file, with Begin and End as the first and last lines respectively and each intermediate line defining a single optional parameter. For example,

```
Begin
  Print Level = 1
End
```

The call

```
CALL E04UDF (IOPTNS, INFORM)
```

can then be used to read the file on unit IOPTNS. INFORM will be zero on successful exit. E04UDF should be consulted for a full description of this method of supplying optional parameters.

E04UEF can be called directly to supply options, one call being necessary for each optional parameter. For example,

```
CALL E04UEF ("Print level = 1")
```

E04UEF should be consulted for a full description of this method of supplying optional parameters.

All optional parameters not specified by the user are set to their default values. Optional parameters specified by the user are unaltered by E04UCF (unless they define invalid values) and so remain in effect for subsequent calls to E04UCF, unless altered by the user.

5.1.2. Description of the optional parameters

The following list (in alphabetical order) gives the valid options. For each option, we give the keyword, any essential optional qualifiers, the default value, and the definition. The minimum valid abbreviation of each keyword is underlined. If no characters of an optional qualifier are underlined, the qualifier may be omitted. The letter a denotes a phrase (character string) that qualifies an option. The letters i and r denote INTEGER and DOUBLE PRECISION values required with certain options. The number (epsilon) is a generic notation for machine precision (see X02AJF(*)), and (epsilon) denotes the relative precision of the objective function (the optional parameter Function Precision see below).
Central Difference Interval \( r \) Default values are computed

If the algorithm switches to central differences because the forward-difference approximation is not sufficiently accurate, the value of \( r \) is used as the difference interval for every component of \( x \). The use of finite-differences is discussed further below under the optional parameter Difference Interval.

Cold Start Default = Cold Start

Warm Start

(Axiom parameter STA, warm start when .TRUE.)

This option controls the specification of the initial working set in both the procedure for finding a feasible point for the linear constraints and bounds, and in the first QP subproblem thereafter. With a Cold Start, the first working set is chosen by E04UCF based on the values of the variables and constraints at the initial point. Broadly speaking, the initial working set will include equality constraints and bounds or inequality constraints that violate or 'nearly' satisfy their bounds (within Crash Tolerance; see below). With a Warm Start, the user must set the ISTATE array and define CLAMDA and R as discussed in Section 5. ISTATE values associated with bounds and linear constraints determine the initial working set of the procedure to find a feasible point with respect to the bounds and linear constraints. ISTATE values associated with nonlinear constraints determine the initial working set of the first QP subproblem after such a feasible point has been found. E04UCF will override the user's specification of ISTATE if necessary, so that a poor choice of the working set will not cause a fatal error. A warm start will be advantageous if a good estimate of the initial working set is available - for example, when E04UCF is called repeatedly to solve related problems.

Crash Tolerance \( r \) Default = 0.01

(Axiom parameter CRA)

This value is used in conjunction with the optional parameter Cold Start (the default value). When making a cold start, the QP algorithm in E04UCF must select an initial working set. When \( r > 0 \), the initial working set will include (if possible) bounds or general inequality constraints that lie within \( r \) of their bounds.

In particular, a constraint of the form \( a_j^T x \geq 1 \) will be included
in the initial working set if $|a-x|_j \leq r(1+|l|)$. If $r<0$ or $r>1$, the default value is used.

 Defaults

 This special keyword may be used to reset the default values following a call to E04UCF.

 Derivative Level $i$ Default = 3

 (Axiom parameter DER)

 This parameter indicates which derivatives are provided by the user in subroutines OBJFUN and CONFUN. The possible choices for $i$ are the following.

<table>
<thead>
<tr>
<th>$i$</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>All objective and constraint gradients are provided by the user.</td>
</tr>
<tr>
<td>2</td>
<td>All of the Jacobian is provided, but some components of the objective gradient are not specified by the user.</td>
</tr>
<tr>
<td>1</td>
<td>All elements of the objective gradient are known, but some elements of the Jacobian matrix are not specified by the user.</td>
</tr>
<tr>
<td>0</td>
<td>Some elements of both the objective gradient and the Jacobian matrix are not specified by the user.</td>
</tr>
</tbody>
</table>

 The value $i=3$ should be used whenever possible, since E04UCF is more reliable and will usually be more efficient when all derivatives are exact.

 If $i=0$ or 2, E04UCF will estimate the unspecified components of the objective gradient, using finite differences. The computation of finite-difference approximations usually increases the total run-time, since a call to OBJFUN is required for each unspecified element. Furthermore, less accuracy can be attained in the solution (see Chapter 8 of Gill et al [10], for a discussion of limiting accuracy).

 If $i=0$ or 1, E04UCF will approximate unspecified elements of the Jacobian. One call to CONFUN is needed for each variable for which partial derivatives are not available. For example, if the Jacobian has the form

 $$(* * * *)$$
where '*' indicates an element provided by the user and '?' indicates an unspecified element, E04UCF will call CONFUN twice: once to estimate the missing element in column 2, and again to estimate the two missing elements in column 3. (Since columns 1 and 4 are known, they require no calls to CONFUN.)

At times, central differences are used rather than forward differences, in which case twice as many calls to OBJFUN and CONFUN are needed. (The switch to central differences is not under the user’s control.)

Difference Interval r Default values are computed

(Axiom parameter DIF)

This option defines an interval used to estimate gradients by finite differences in the following circumstances:

(a) For verifying the objective and/or constraint gradients (see the description of Verify, below).

(b) For estimating unspecified elements of the objective gradient of the Jacobian matrix.

In general, a derivative with respect to the jth variable is approximated using the interval (delta), where (delta) \(=r(1+|x|)\) with x the first point feasible with respect to the bounds and linear constraints. If the functions are well scaled, the resulting derivative approximation should be accurate to \(O(r)\).

See Gill et al [10] for a discussion of the accuracy in finite-difference approximations.

If a difference interval is not specified by the user, a finite-difference interval will be computed automatically for each variable by a procedure that requires up to six calls of CONFUN and OBJFUN for each component. This option is recommended if the function is badly scaled or the user wishes to have E04UCF determine constant elements in the objective and constraint gradients (see the descriptions of CONFUN and OBJFUN in Section 5).
Feasibility Tolerance r Default = $/\text{epsilon}$

(Axiom parameter FEA)

The scalar $r$ defines the maximum acceptable absolute violations in linear and nonlinear constraints at a 'feasible' point; i.e., a constraint is considered satisfied if its violation does not exceed $r$. If $r<(\text{epsilon})$ or $r\geq1$, the default value is used. Using this keyword sets both optional parameters Linear Feasibility Tolerance and Nonlinear Feasibility Tolerance to $r$, if $(\text{epsilon})\leq r<1$. (Additional details are given below under the descriptions of these parameters.)

0.9

Function Precision $r$ Default = $(\text{epsilon})$

(Axiom parameter FUN)

This parameter defines $(\text{epsilon})$, which is intended to be a measure of the accuracy with which the problem functions $f$ and $c$ can be computed. If $r<(\text{epsilon})$ or $r\geq1$, the default value is used. The value of $(\text{epsilon})$ should reflect the relative precision of $1+|F(x)|$; i.e., $(\text{epsilon})$ acts as a relative precision when $|F|$ is large, and as an absolute precision when $|F|$ is small. For example, if $F(x)$ is typically of order 1000 and the first six significant digits are known to be correct, an appropriate value for $(\text{epsilon})$ would be $1.0E^{-6}$. In contrast, if $F(x)$ is typically of order $10^{-4}$ and the first six significant digits are known to be correct, an appropriate value for $(\text{epsilon})$ would be $1.0E^{-10}$. The choice of $(\text{epsilon})$ can be quite complicated for badly scaled problems; see Chapter 8 of Gill et al [10] for a discussion of scaling techniques. The default value is appropriate for most simple functions that are computed with full accuracy. However, when the accuracy of the computed function values is known to be significantly worse than full precision, the value of $(\text{epsilon})$ should be large enough so that E04UCF will not attempt to distinguish between function values that differ by less than the error inherent in the calculation.

Hessian No Default = No

Hessian Yes
This option controls the contents of the upper-triangular matrix \( R \) (see Section 5). E04UCF works exclusively with the transformed and re-ordered Hessian \( H \) (6), and hence extra computation is required to form the Hessian itself. If Hessian = No, \( R \) contains the Cholesky factor of the transformed and re-ordered Hessian. If Hessian = Yes the Cholesky factor of the approximate Hessian itself is formed and stored in \( R \). The user should select Hessian = Yes if a warm start will be used for the next call to E04UCF.

Infinite Bound Size \( r \) Default = 10

(Axiom parameter INFB)

If \( r > 0 \), \( r \) defines the 'infinite' bound BIGBND in the definition of the problem constraints. Any upper bound greater than or equal to BIGBND will be regarded as plus infinity (and similarly for a lower bound less than or equal to -BIGBND). If \( r \leq 0 \), the default value is used.

Infinite Step Size \( r \) Default = max(BIGBND,10)

(Axiom parameter INFS)

If \( r > 0 \), \( r \) specifies the magnitude of the change in variables that is treated as a step to an unbounded solution. If the change in \( x \) during an iteration would exceed the value of Infinite Step Size, the objective function is considered to be unbounded below in the feasible region. If \( r \leq 0 \), the default value is used.

Iteration limit \( i \) Default = max(50,3(n+n)+10n)

See Major Iteration Limit below.

Linear Feasibility Tolerance \( r \) Default = \( \sqrt{\text{epsilon}} \)

(Axiom parameter LINF)

Nonlinear Feasibility Tolerance \( r \) Default = \( \sqrt{\text{epsilon}} \) if

\( \text{---} \)

\( \text{---} \)
Derivative Level $\geq 2$ and $(\epsilon)$ otherwise

The scalars $r_1$ and $r_2$ define the maximum acceptable absolute violations in linear and nonlinear constraints at a 'feasible' point; i.e., a linear constraint is considered satisfied if its violation does not exceed $r_1$, and similarly for a nonlinear constraint and $r_i$. If $r_i < (\epsilon)$ or $r_i \geq 1$, the default value is used, for $i=1,2$.

On entry to E04UCF, an iterative procedure is executed in order to find a point that satisfies the linear constraint and bounds on the variables to within the tolerance $r_1$. All subsequent iterates will satisfy the linear constraints to within the same tolerance (unless $r_1$ is comparable to the finite-difference interval).

For nonlinear constraints, the feasibility tolerance $r_2$ defines the largest constraint violation that is acceptable at an optimal point. Since nonlinear constraints are generally not satisfied until the final iterate, the value of Nonlinear Feasibility Tolerance acts as a partial termination criterion for the iterative sequence generated by E04UCF (see the discussion of Optimality Tolerance).

These tolerances should reflect the precision of the corresponding constraints. For example, if the variables and the coefficients in the linear constraints are of order unity, and the latter are correct to about 6 decimal digits, it would be appropriate to specify $r_1 = 10^{-6}$.

Linesearch Tolerance $r$ Default $= 0.9$

The value $r$ ($0 \leq r < 1$) controls the accuracy with which the step (alpha) taken during each iteration approximates a minimum of the merit function along the search direction (the smaller the value of $r$, the more accurate the linesearch). The default value $r=0.9$ requests an inaccurate search, and is appropriate for most
problems, particularly those with any nonlinear constraints.

If there are no nonlinear constraints, a more accurate search may be appropriate when it is desirable to reduce the number of major iterations — for example, if the objective function is cheap to evaluate, or if a substantial number of gradients are unspecified.

List Default = List

Nolist

(Axiom parameter LIST)

Normally each optional parameter specification is printed as it is supplied. Nolist may be used to suppress the printing and List may be used to restore printing.

Major Iteration Limit i Default = max(50,3(n+n)+10n)

IterLimit

Itns

(Axiom parameter MAJI)

The value of i specifies the maximum number of major iterations allowed before termination. Setting i=0 and Major Print Level > 0 means that the workspace needed will be computed and printed, but no iterations will be performed.

Major Print level i Default = 10

Print Level

(Axiom parameter MAJP)

The value of i controls the amount of printout produced by the major iterations of E04UCF. (See also Minor Print level below.) The levels of printing are indicated below.

i Output

0 No output.

1 The final solution only.
5 One line for each major iteration (no printout of the final solution).

>=10 The final solution and one line of output for each iteration.

>=20 At each major iteration, the objective function, the Euclidean norm of the nonlinear constraint violations, the values of the nonlinear constraints (the vector $c$), the values of the linear constraints (the vector $Ax$), and the current values of the variables (the vector $x$).

>=30 At each major iteration, the diagonal elements of the matrix $T$ associated with the TQ factorization (5) of the QP working set, and the diagonal elements of $R$, the triangular factor of the transformed and re-ordered Hessian (6).

Minor Iteration Limit $i$ Default = $\max(50, 3(n+N))$

(Axiom parameter MINI)

The value of $i$ specifies the maximum number of iterations for the optimality phase of each QP subproblem.

Minor Print Level $i$ Default = 0

(Axiom parameter MINP)

The value of $i$ controls the amount of printout produced by the minor iterations of E04UCF, i.e., the iterations of the quadratic programming algorithm. (See also Major Print Level, above.) The following levels of printing are available.

1 The final QP solution.

5 One line of output for each minor iteration (no printout of the final QP solution).

>=10 The final QP solution and one brief line of output for each minor iteration.

>=20 At each minor iteration, the current estimates of the QP multipliers, the current estimate of the QP search
direction, the QP constraint values, and the status of each QP constraint.

>=30  At each minor iteration, the diagonal elements of the matrix T associated with the TQ factorization (5) of the QP working set, and the diagonal elements of the Cholesky factor R of the transformed Hessian (6).

Nonlinear Feasibility Tolerance r Default = \( \sqrt{\varepsilon} \)

See Linear Feasibility Tolerance, above.

Optimality Tolerance r Default = (\( \varepsilon \))

(Axiom parameter OPT)

The parameter r ((\( \varepsilon \)) \( \leq r < 1 \)) specifies the accuracy to which the user wishes the final iterate to approximate a solution of the problem. Broadly speaking, r indicates the number of correct figures desired in the objective function at the solution. For example, if r is 10\(-6\) and E04UCF terminates successfully, the final value of F should have approximately six correct figures. If r<(\( \varepsilon \)) or r\( \geq 1 \) the default value is used.

E04UCF will terminate successfully if the iterative sequence of x-values is judged to have converged and the final point satisfies the first-order Kuhn-Tucker conditions (see Section 3). The sequence of iterates is considered to have converged at x if

\[
\frac{\alpha}{||p||} \leq \sqrt{r(1+||x||)}, \quad (8a)
\]

where p is the search direction and (\( \alpha \)) the step length from (3). An iterate is considered to satisfy the first-order conditions for a minimum if

\[
\frac{||Z g||}{FR} \leq \sqrt{r(1+\max(1+|F(x)|,||g||))} \quad (8b)
\]

and

\[
|res_j| \leq ftol \text{ for all } j, \quad (8c)
\]
where \( z_g \) is the projected gradient (see Section 3), \( g \) is the gradient of \( F(x) \) with respect to the free variables, \( res \) is the violation of the \( j \)th active nonlinear constraint, and \( ftol \) is the Nonlinear Feasibility Tolerance.

Step Limit \( r \) Default = 2.0

(Axiom parameter STE)

If \( r > 0 \), \( r \) specifies the maximum change in variables at the first step of the linesearch. In some cases, such as \( F(x) = ae \) or \( b \) even a moderate change in the components of \( x \) can lead to floating-point overflow. The parameter \( r \) is therefore used to encourage evaluation of the problem functions at meaningful points. Given any major iterate \( x \), the first point \( x' \) at which \( F \) and \( c \) are evaluated during the linesearch is restricted so that

\[ ||x-x'|| \leq r(1+||x'||). \]

The linesearch may go on and evaluate \( F \) and \( c \) at points further from \( x \) if this will result in a lower value of the merit function. In this case, the character \( L \) is printed at the end of the optional line of printed output, (see Section 5.2). If \( L \) is printed for most of the iterations, \( r \) should be set to a larger value.

Wherever possible, upper and lower bounds on \( x \) should be used to prevent evaluation of nonlinear functions at wild values. The default value Step Limit = 2.0 should not affect progress on well-behaved functions, but values 0.1 or 0.01 may be helpful when rapidly varying functions are present. If a small value of Step Limit is selected, a good starting point may be required. An important application is to the class of nonlinear least-squares problems. If \( r \leq 0 \), the default value is used.

Start Objective Check At Variable \( k \) Default = 1

(Axiom parameter STAO)

Start Constraint Check At Variable \( k \) Default = 1

(Axiom parameter STAC)
Stop Objective Check At Variable l Default = n

(Axiom parameter STDD)

Stop Constraint Check At Variable l Default = n

(Axiom parameter STDC)

These keywords take effect only if Verify Level > 0 (see below). They may be used to control the verification of gradient elements computed by subroutines OBJFUN and CONFUN. For example, if the first 30 components of the objective gradient appeared to be correct in an earlier run, so that only component 31 remains questionable, it is reasonable to specify Start Objective Check At Variable 31. If the first 30 variables appear linearly in the objective, so that the corresponding gradient elements are constant, the above choice would also be appropriate.

Verify Level i Default = 0

Verify No

Verify Level - 1

Verify Level 0

Verify Objective Gradients

Verify Level 1

Verify Constraint Gradients

Verify Level 2

Verify

Verify Yes

Verify Gradients

Verify Level 3

(Axiom parameter VE)

These keywords refer to finite-difference checks on the gradient elements computed by the user-provided subroutines OBJFUN and CONFUN. (Unspecified gradient components are not checked.) It is possible to specify Verify Levels 0–3 in several ways, as indicated above. For example, the nonlinear objective gradient
(if any) will be verified if either Verify Objective Gradients or Verify Level 1 is specified. Similarly, the objective and the constraint gradients will be verified if Verify Yes or Verify Level 3 or Verify is specified.

If \(0 \leq i \leq 3\), gradients will be verified at the first point that satisfies the linear constraints and bounds. If \(i=0\), only a 'cheap' test will be performed, requiring one call to OBJFUN and one call to CONFUN. If \(1 \leq i \leq 3\), a more reliable (but more expensive) check will be made on individual gradient components, within the ranges specified by the Start and Stop keywords described above. A result of the form OK or BAD? is printed by E04UCF to indicate whether or not each component appears to be correct.

If \(10 \leq i \leq 13\), the action is the same as for \(i - 10\), except that it will take place at the user-specified initial value of \(x\).

We suggest that Verify Level 3 be specified whenever a new function routine is being developed.

5.1.3. Optional parameter checklist and default values

For easy reference, the following list shows all the valid keywords and their default values. The symbol (epsilon) represents the machine precision (see X02AJF(*)).

5.2. Description of Printed Output

The level of printed output from E04UCF is controlled by the user
(see the description of Major Print Level and Minor Print Level in Section 5.1). If Minor Print Level > 0, output is obtained from the subroutines that solve the QP subproblem. For a detailed description of this information the reader should refer to E04NCF(*).

When Major Print Level >= 5, the following line of output is produced at every major iteration of E04UCF. In all cases, the values of the quantities printed are those in effect on completion of the given iteration.

\[ \text{Itn} \quad \text{is the iteration count.} \]

\[ \text{ItQP} \quad \text{is the sum of the iterations required by the feasibility and optimality phases of the QP subproblem. Generally, ItQP will be 1 in the later iterations, since theoretical analysis predicts that the correct active set will be identified near the solution (see Section 3).} \]

Note that ItQP may be greater than the Minor Iteration Limit if some iterations are required for the feasibility phase.

\[ \text{Step} \quad \text{is the step (alpha) taken along the computed search direction. On reasonably well-behaved problems, the unit step will be taken as the solution is approached.} \]

\[ \text{Nfun} \quad \text{is the cumulative number of evaluations of the objective function needed for the linesearch. Evaluations needed for the estimation of the gradients by finite differences are not included. Nfun is printed as a guide to the amount of work required for the linesearch.} \]

\[ \text{Merit} \quad \text{is the value of the augmented Lagrangian merit function (12) at the current iterate. This function will decrease at each iteration unless it was necessary to increase the penalty parameters (see Section 8.2). As the solution is approached, Merit will converge to the value of the objective function at the solution.} \]

If the QP subproblem does not have a feasible point (signified by I at the end of the current output line), the merit function is a large multiple of the constraint violations, weighted by the penalty parameters. During a sequence of major iterations with infeasible subproblems, the
sequence of Merit values will decrease monotonically until either a feasible subproblem is obtained or E04UCF terminates with IFAIL = 3 (no feasible point could be found for the nonlinear constraints).

If no nonlinear constraints are present (i.e., NCNLN = 0), this entry contains Objective, the value of the objective function F(x). The objective function will decrease monotonically to its optimal value when there are no nonlinear constraints.

Bnd is the number of simple bound constraints in the predicted active set.

Lin is the number of general linear constraints in the predicted active set.

Nln is the number of nonlinear constraints in the predicted active set (not printed if NCNLN is zero).

Nz is the number of columns of Z (see Section 8.1). The value of Nz is the number of variables minus the number of constraints in the predicted active set; i.e., Nz = n-(Bnd + Lin + Nln).

Norm Gf is the Euclidean norm of g, the gradient of the FR objective function with respect to the free variables, i.e., variables not currently held at a bound.

\[ \|Z g\| \], the Euclidean norm of the projected FR gradient (see Section 8.1). Norm Gz will be approximately zero in the neighbourhood of a solution.

Cond H is a lower bound on the condition number of the Hessian approximation H.

Cond Hz is a lower bound on the condition number of the projected Hessian approximation H (with an upper bound given by the unit diagonal of H), see (6) and (12) in Sections 3 and 4.
The larger this number, the more difficult the problem.

Cond T is a lower bound on the condition number of the matrix of predicted active constraints.

Norm C is the Euclidean norm of the residuals of constraints that are violated or in the predicted active set (not printed if NCNLN is zero). Norm C will be approximately zero in the neighbourhood of a solution.

Penalty is the Euclidean norm of the vector of penalty parameters used in the augmented Lagrangian merit function (not printed if NCNLN is zero).

Conv is a three-letter indication of the status of the three convergence tests (8a)-(8c) defined in the description of the optional parameter Optimality Tolerance in Section 5.1 Each letter is T if the test is satisfied, and F otherwise. The three tests indicate whether:

(a) the sequence of iterates has converged;

(b) the projected gradient (Norm Gz) is sufficiently small; and

(c) the norm of the residuals of constraints in the predicted active set (Norm C) is small enough.

If any of these indicators is F when E04UCF terminates with IFAIL = 0, the user should check the solution carefully.

M is printed if the Quasi-Newton update was modified to ensure that the Hessian approximation is positive-definite (see Section 8.3).

I is printed if the QP subproblem has no feasible point.

C is printed if central differences were used to compute the unspecified objective and constraint gradients. If the value of Step is zero, the switch to central differences was made because no lower point could be found in the linesearch. (In this case, the QP subproblem is resolved with the central-difference gradient and Jacobian.) If the value of Step is non-zero, central differences were computed because Norm Gz and Norm C imply
that \( x \) is close to a Kuhn-Tucker point.

**L** is printed if the linesearch has produced a relative change in \( x \) greater than the value defined by the optional parameter Step Limit. If this output occurs frequently during later iterations of the run, Step Limit should be set to a larger value.

**R** is printed if the approximate Hessian has been refactorized. If the diagonal condition estimator of \( R \) indicates that the approximate Hessian is badly conditioned, the approximate Hessian is refactorized using column interchanges. If necessary, \( R \) is modified so that its diagonal condition estimator is bounded.

When Major Print Level = 1 or Major Print Level >= 10, the summary printout at the end of execution of E04UCF includes a listing of the status of every variable and constraint. Note that default names are assigned to all variables and constraints.

The following describes the printout for each variable.

**Varbl** gives the name (\( V \)) and index \( j=1,2,...,n \) of the variable.

**State** gives the state of the variable in the predicted active set (FR if neither bound is in the active set, EQ if a fixed variable, LL if on its lower bound, UL if on its upper bound). If the variable is predicted to lie outside its upper or lower bound by more than the feasibility tolerance, State will be ++ or -- respectively. (The latter situation can occur only when there is no feasible point for the bounds and linear constraints.)

**Value** is the value of the variable at the final iteration.

**Lower bound** is the lower bound specified for the variable. (None indicates that \( BL(j) \leq -\text{BIGBND} \).)

**Upper bound** is the upper bound specified for the variable. (None indicates that \( BL(j) \geq \text{BIGBND} \).)

**Lagr Mult** is the value of the Lagrange-multiplier for the associated bound constraint. This will be zero if State is FR. If \( x \) is optimal, the multiplier should be non-negative if State is LL, and non-
positive if State is UL.

Residual is the difference between the variable Value and the nearer of its bounds BL(j) and BU(j).

The printout for general constraints is the same as for variables, except for the following:

L Con is the name (L) and index i, for i = 1,2,...,NCLIN of a linear constraint.

N Con is the name (N) and index i, for i = 1,2,...,NCNLN of a nonlinear constraint.

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

The input data for E04UCF should always be checked (even if E04UCF terminates with IFAIL=0).

Note that when Print Level>0, a short description of IFAIL is printed.

Errors and diagnostics indicated by IFAIL, together with some recommendations for recovery are indicated below.

IFAIL= 1
The final iterate x satisfies the first-order Kuhn-Tucker conditions to the accuracy requested, but the sequence of iterates has not yet converged. E04UCF was terminated because no further improvement could be made in the merit function.

This value of IFAIL may occur in several circumstances. The most common situation is that the user asks for a solution with accuracy that is not attainable with the given precision of the problem (as specified by Function Precision see Section 5). This condition will also occur if, by chance, an iterate is an 'exact' Kuhn-Tucker point, but the change in the variables was significant at the previous iteration. (This situation often happens when minimizing very simple functions, such as quadratics.)

If the four conditions listed in Section 5 for IFAIL = 0 are satisfied, x is likely to be a solution of (1) even if IFAIL = 1.
IFAIL = 2
E04UCF has terminated without finding a feasible point for
the linear constraints and bounds, which means that no
feasible point exists for the given value of Linear
Feasibility Tolerance (see Section 5.1). The user should
check that there are no constraint redundancies. If the data
for the constraints are accurate only to an absolute
precision (sigma), the user should ensure that the value of
the optional parameter Linear Feasibility Tolerance is
greater than (sigma). For example, if all elements of A are
of order unity and are accurate to only three decimal
places, Linear Feasibility Tolerance should be at least 10⁻³.

IFAIL = 3
No feasible point could be found for the nonlinear
constraints. The problem may have no feasible solution. This
means that there has been a sequence of QP subproblems for
which no feasible point could be found (indicated by I at
the end of each terse line of output). This behaviour will
occur if there is no feasible point for the nonlinear
constraints. (However, there is no general test that can
determine whether a feasible point exists for a set of
nonlinear constraints.) If the infeasible subproblems occur
from the very first major iteration, it is highly likely
that no feasible point exists. If infeasibilities occur when
earlier subproblems have been feasible, small constraint
inconsistencies may be present. The user should check the
validity of constraints with negative values of ISTATE. If
the user is convinced that a feasible point does exist,
E04UCF should be restarted at a different starting point.

IFAIL = 4
The limiting number of iterations (determined by the
optional parameter Major Iteration Limit see Section 5.1)
has been reached.

If the algorithm appears to be making progress, Major
Iteration Limit may be too small. If so, increase its value
and rerun E04UCF (possibly using the Warm Start option). If
the algorithm seems to be ‘bogged down’, the user should
check for incorrect gradients or ill-conditioning as
described below under IFAIL = 6.

Note that ill-conditioning in the working set is sometimes
resolved automatically by the algorithm, in which case
performing additional iterations may be helpful. However,
ill-conditioning in the Hessian approximation tends to
persist once it has begun, so that allowing additional
iterations without altering R is usually inadvisable. If the quasi-Newton update of the Hessian approximation was modified during the latter iterations (i.e., an M occurs at the end of each terse line), it may be worthwhile to try a warm start at the final point as suggested above.

**IFAIL = 6**

x does not satisfy the first-order Kuhn-Tucker conditions, and no improved point for the merit function could be found during the final line search.

A sufficient decrease in the merit function could not be attained during the final line search. This sometimes occurs because an overly stringent accuracy has been requested, i.e., Optimality Tolerance is too small. In this case the user should apply the four tests described under IFAIL = 0 above to determine whether or not the final solution is acceptable (see Gill et al [10], for a discussion of the attainable accuracy).

If many iterations have occurred in which essentially no progress has been made and E04UCF has failed completely to move from the initial point then subroutines OBJFUN or CONFUN may be incorrect. The user should refer to comments below under IFAIL = 7 and check the gradients using the Verify parameter. Unfortunately, there may be small errors in the objective and constraint gradients that cannot be detected by the verification process. Finite-difference approximations to first derivatives are catastrophically affected by even small inaccuracies. An indication of this situation is a dramatic alteration in the iterates if the finite-difference interval is altered. One might also suspect this type of error if a switch is made to central differences even when Norm Gz and Norm C are large.

Another possibility is that the search direction has become inaccurate because of ill-conditioning in the Hessian approximation or the matrix of constraints in the working set; either form of ill-conditioning tends to be reflected in large values of ItQP (the number of iterations required to solve each QP subproblem).

If the condition estimate of the projected Hessian (Cond Hz) is extremely large, it may be worthwhile to rerun E04UCF from the final point with the Warm Start option. In this situation, ISTATE should be left unaltered and R should be reset to the identity matrix.

If the matrix of constraints in the working set is ill-conditioned (i.e., Cond T is extremely large), it may be
helpful to run E04UCF with a relaxed value of the Feasibility Tolerance (Constraint dependencies are often indicated by wide variations in size in the diagonal elements of the matrix $T$, whose diagonals will be printed for Major Print Level $\geq 30$).

IFAIL= 7
The user-provided derivatives of the objective function and/or nonlinear constraints appear to be incorrect.

Large errors were found in the derivatives of the objective function and/or nonlinear constraints. This value of IFAIL will occur if the verification process indicated that at least one gradient or Jacobian component had no correct figures. The user should refer to the printed output to determine which elements are suspected to be in error.

As a first-step, the user should check that the code for the objective and constraint values is correct - for example, by computing the function at a point where the correct value is known. However, care should be taken that the chosen point fully tests the evaluation of the function. It is remarkable how often the values $x=0$ or $x=1$ are used to test function evaluation procedures, and how often the special properties of these numbers make the test meaningless.

Special care should be used in this test if computation of the objective function involves subsidiary data communicated in COMMON storage. Although the first evaluation of the function may be correct, subsequent calculations may be in error because some of the subsidiary data has accidently been overwritten.

Errors in programming the function may be quite subtle in that the function value is 'almost' correct. For example, the function may not be accurate to full precision because of the inaccurate calculation of a subsidiary quantity, or the limited accuracy of data upon which the function depends. A common error on machines where numerical calculations are usually performed in double precision is to include even one single-precision constant in the calculation of the function; since some compilers do not convert such constants to double precision, half the correct figures may be lost by such a seemingly trivial error.

IFAIL= 9
An input parameter is invalid. The user should refer to the printed output to determine which parameter must be redefined.
Although overflow may occur in the working set, which contains a warning about serious ill-conditioning in the working set when adding the jth constraint, it may be possible to avoid the difficulty by increasing the magnitude of the optional parameter Linear Feasibility Tolerance or Nonlinear Feasibility Tolerance, and rerunning the program. If the message recurs even after this change, the offending linearly dependent constraint (with index 'j') must be removed from the problem. If overflow occurs in one of the user-supplied routines (e.g. if the nonlinear functions involve exponentials or singularities), it may help to specify tighter bounds for some of the variables (i.e., reduce the gap between appropriate l and u).

7. Accuracy

If IFAIL = 0 on exit then the vector returned in the array X is an estimate of the solution to an accuracy of approximately Feasibility Tolerance (see Section 5.1), whose default value is $0.8 \times \epsilon$, where $\epsilon$ is the machine precision (see X02AJF(*)).

8. Further Comments

In this section we give some further details of the method used by E04UCF.

8.1. Solution of the Quadratic Programming Subproblem

The search direction $p$ is obtained by solving (4) using the method of E04NCF(*) (Gill et al [8]), which was specifically designed to be used within an SQP algorithm for nonlinear programming.

The method of E04UCF is a two-phase (primal) quadratic programming method. The two phases of the method are: finding an initial feasible point by minimizing the sum of infeasibilities (the feasibility phase), and minimizing the quadratic objective function within the feasible region (the optimality phase). The computations in both phases are performed by the same subroutines. The two-phase nature of the algorithm is reflected by changing the function being minimized from the sum of infeasibilities to the quadratic objective function.

In general, a quadratic program must be solved by iteration. Let $p$ denote the current estimate of the solution of (4); the new
iterate \( p \) is defined by

\[
p = p + \sigma d,
\]

where, as in (3), \( \sigma \) is a non-negative step length and \( d \) is a search direction.

At the beginning of each iteration of E04UCF, a working set is defined of constraints (general and bound) that are satisfied exactly. The vector \( d \) is then constructed so that the values of constraints in the working set remain unaltered for any move along \( d \). For a bound constraint in the working set, this property is achieved by setting the corresponding component of \( d \) to zero, i.e., by fixing the variable at its bound. As before, the subscripts 'FX' and 'FR' denote selection of the components associated with the fixed and free variables.

Let \( C \) denote the sub-matrix of rows of

\[
\begin{pmatrix}
A \\
L \\
A \\
N
\end{pmatrix}
\]

corresponding to general constraints in the working set. The general constraints in the working set will remain unaltered if

\[
C_{\text{FR}} d_{\text{FR}} = 0,
\]

which is equivalent to defining \( d_{\text{FR}} \) as

\[
d_{\text{FR}} = Z d_{\text{FR}}
\]

for some vector \( d_{\text{z}} \), where \( Z \) is the matrix associated with the TQ factorization (5) of \( C_{\text{z}} \).

The definition of \( d_{\text{z}} \) in (11) depends on whether the current \( p \) is feasible. If not, \( d_{\text{z}} \) is zero except for a component \((\gamma)\) in the jth position, where j and \((\gamma)\) are chosen so that the sum of infeasibilities is decreasing along \( d \). (For further details, see Gill et al [8].) In the feasible case, \( d_{\text{z}} \) satisfies the
equations

\[ R R \ d = -Z \ q , \quad (12) \]

where \( R \) is the Cholesky factor of \( Z H Z \) and \( q \) is the gradient of the quadratic objective function \((q = g + H p)\). (The vector \( Z q \) is the projected gradient of the QP.) With (12), \( P + d \) is the minimizer of the quadratic objective function subject to treating the constraints in the working set as equalities.

If the QP projected gradient is zero, the current point is a constrained stationary point in the subspace defined by the working set. During the feasibility phase, the projected gradient will usually be zero only at a vertex (although it may vanish at non-vertices in the presence of constraint dependencies). During the optimality phase, a zero projected gradient implies that \( p \) minimizes the quadratic objective function when the constraints in the working set are treated as equalities. In either case, Lagrange multipliers are computed. Given a positive constant \((\delta)\) of the order of the machine precision, the Lagrange multiplier \((\mu_j)\) corresponding to an inequality constraint in the working set at its upper bound is said to be optimal if \((\mu_j) \leq (\delta)\) when the \( j \)th constraint is at its upper bound, or \((\mu_j) > - (\delta)\) when the associated constraint is at its lower bound. If any multiplier is non-optimal, the current objective function (either the true objective or the sum of infeasibilities) can be reduced by deleting the corresponding constraint from the working set.

If optimal multipliers occur during the feasibility phase and the sum of infeasibilities is non-zero, no feasible point exists. The QP algorithm will then continue iterating to determine the minimum sum of infeasibilities. At this point, the Lagrange multiplier \((\mu_j)\) will satisfy \(-(1 + (\delta)) <= (\mu_j) <= (\delta)\) for an \( j \) inequality constraint at its upper bound, and \(-(\delta) <= (\mu_j) <= 1 + (\delta)\) for an inequality at its lower bound. The Lagrange multiplier for an equality constraint will satisfy \(|(\mu_j)| <= 1 + (\delta)\).
The choice of step length \((\sigma)\) in the QP iteration (9) is based on remaining feasible with respect to the satisfied constraints. During the optimality phase, if \(p+d\) is feasible, \((\sigma)\) will be taken as unity. (In this case, the projected gradient at \(p\) will be zero.) Otherwise, \((\sigma)\) is set to \((\sigma)\), the step to the 'nearest' constraint, which is added to the working set at the next iteration.

Each change in the working set leads to a simple change to \(C\):

\[ \text{if the status of a general constraint changes, a row of } C \text{ is altered; if a bound constraint enters or leaves the working set, a column of } C \text{ changes. Explicit representations are recurred of } \begin{bmatrix} T & T \\ Q & Q \end{bmatrix} \text{ and of the vectors } Q q \text{ and } Q g. \]

8.2. The Merit Function

After computing the search direction as described in Section 3, each major iteration proceeds by determining a step length \((\alpha)\) in (3) that produces a 'sufficient decrease' in the augmented Lagrangian merit function

\[
L(x, (\lambda), s) = F(x) - > (\lambda) (c(x) - s) 
- > i  
+ - > (\rho) (c(x) - s), \quad \text{(13)}
2 -- i i i
\]

where \(x\), \((\lambda)\) and \(s\) vary during the linsearch. The summation terms in (13) involve only the nonlinear constraints. The vector \((\lambda)\) is an estimate of the Lagrange multipliers for the nonlinear constraints of (1). The non-negative slack variables \({s}\) allow nonlinear inequality constraints to be treated without introducing discontinuities. The solution of the QP subproblem (4) provides a vector triple that serves as a direction of search for the three sets of variables. The non-negative vector \((\rho)\) of penalty parameters is initialised to zero at the beginning of the
first major iteration. Thereafter, selected components are increased whenever necessary to ensure descent for the merit function. Thus, the sequence of norms of \((\rho_i)\) (the printed quantity Penalty, see Section 5.2) is generally non-decreasing, although each \((\rho_i)\) may be reduced a limited number of times.

The merit function (13) and its global convergence properties are described in Gill et al [9].

8.3. The Quasi-Newton Update

The matrix \(H\) in (4) is a positive-definite quasi-Newton approximation to the Hessian of the Lagrangian function. (For a review of quasi-Newton methods, see Dennis and Schnabel [3].) At the end of each major iteration, a new Hessian approximation \(H\) is defined as a rank-two modification of \(H\). In E04UCF, the BFGS quasi-Newton update is used:

\[
H = H - \frac{1}{s^T H s} H s y + \frac{1}{y^T s} s H y,
\]

(14)

where \(s = x - x\) (the change in \(x\)).

In E04UCF, \(H\) is required to be positive-definite. If \(H\) is positive-definite, \(H\) defined by (14) will be positive-definite if and only if \(y^T s\) is positive (see, e.g. Dennis and More [1]). Ideally, \(y\) in (14) would be taken as \(y_L\), the change in gradient of the Lagrangian function

\[
y_L = g - A^T (\mu_N) - g + A^T (\mu_N),
\]

(15)

where \((\mu_N)\) denotes the QP multipliers associated with the nonlinear constraints of the original problem. If \(y^T s\) is not sufficiently positive, an attempt is made to perform the update with a vector \(y\) of the form

\[
m
\]
\[ y = y + \sum_{i} \omega (a(x) c(x) - a(x) c(x)), \]

where \( \omega \geq 0 \). If no such vector can be found, the update is performed with a scaled \( y \); in this case, \( M \) is printed to indicate that the update is modified.

Rather than modifying \( H \) itself, the Cholesky factor of the transformed Hessian \( H^{(6)} \) is updated, where \( Q \) is the matrix from \( (5) \) associated with the active set of the QP subproblem. The update \( (13) \) is equivalent to the following update to \( H^{(6)} \):

\[
H = H - \frac{1}{Q^T s} Q^T y + \frac{1}{Q^T s} Q^T y, \quad (16)
\]

where \( y = Q^T y \), and \( s = Q^T s \). This update may be expressed as a rank-

one update to \( R \) (see Dennis and Schnabel [2]).

9. Example

This section describes one version of the so-called 'hexagon' problem (a different formulation is given as Problem 108 in Hock and Schittkowski [11]). The problem is to determine the hexagon of maximum area such that no two of its vertices are more than one unit apart (the solution is not a regular hexagon).

All constraint types are included (bounds, linear, nonlinear), and the Hessian of the Lagrangian function is not positive-definite at the solution. The problem has nine variables, non-infinite bounds on seven of the variables, four general linear constraints, and fourteen nonlinear constraints.

The objective function is

\[
F(x) = -x_2 x_1 + x_4 x - x_5 x - x_6 x + x_8 x + x_9 x.
\]

The bounds on the variables are
Thus,

\[ T = (0, -\infty, -1, -\infty, 0, 0, -\infty, -\infty) \]
\[ B = (\infty, \infty, 1, \infty, \infty, \infty, \infty, 0, 0) \]

The general linear constraints are

\[ x - x \geq 0, x - x \geq 0, x - x \geq 0, \text{ and } x - x \geq 0. \]

Hence,

\[ (0) \begin{pmatrix} -1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} \infty \end{pmatrix} \]
\[ (0) \begin{pmatrix} 0 & -1 & 1 & 0 & 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} \infty \end{pmatrix} \]
\[ l = (0), A = \begin{pmatrix} 0 & 0 & 1 & -1 & 0 & 0 & 0 & 0 \end{pmatrix} \text{ and } u = (\infty). \]
\[ L (0) \begin{pmatrix} 0 & 0 & 0 & 1 & -1 & 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} \infty \end{pmatrix} \]

The nonlinear constraints are all of the form \( c_i(x) \leq 1 \), for \( i = 1, 2, \ldots, 14 \); hence, all components of \( l \) are \( -\infty \), and all components of \( u \) are \( 1 \). The fourteen functions \( \{c_i(x)\} \) are

\[ c_2(x) = x + x, \]
\[ c_2(x) = (x - x) + (x - x), \]
\[ c_2(x) = (x - x) + x, \]
\[ c_2(x) = (x - x) + (x - x), \]
\[ 2 \quad 2 \quad 2 \quad 2 \quad 2 \quad 2 \quad 2 \quad 2 \quad 2 \quad 2 \quad 2 \quad 2 \quad 2 \quad 2 \]
\[ c_5(x) = (x_1 - x_5) + (x_1 - x_6) + (x_5 - x_9) + x_2, \]
\[ c_6(x) = x_6 + x_7, \]
\[ c_7(x) = (x_1 - x_7) + x_3, \]
\[ c_8(x) = (x_2 - x_5) + (x_2 - x_8) + (x_5 - x_9) + x_2, \]
\[ c_9(x) = x_9 + x_10 + x_11, \]
\[ c_{10}(x) = (x_2 - x_5) + (x_2 - x_8) + (x_5 - x_9) + x_2, \]
\[ c_{11}(x) = x_9 + x_10 + x_11, \]
\[ c_{12}(x) = x_12 + x_13 + x_14, \]
\[ c_{13}(x) = (x_2 - x_5) + (x_2 - x_8) + (x_5 - x_9) + x_2, \]
\[ c_{14}(x) = x_9 + x_10 + x_11, \]

An optimal solution (to five figures) is

\[ x^* = (0.060947, 0.59765, 1.0, 0.59765, 0.060947, 0.34377, 0.5, -0.5, 0.34377), \]

and \( F(x^*) = -1.34996. \) (The optimal objective function is unique, but is achieved for other values of \( x \).) Five nonlinear
constraints and one simple bound are active at \( x \). The sample solution output is given later in this section, following the sample main program and problem definition.

Two calls are made to E04UCF in order to demonstrate some of its features. For the first call, the starting point is:

\[
\begin{align*}
&x = (0.1, 0.125, 0.666666, 0.142857, 0.111111, 0.2, 0.25, -0.2, -0.25) \\
&0
\end{align*}
\]

All objective and constraint derivatives are specified in the user-provided subroutines OBJFN1 and CONFN1, i.e., the default option Derivative Level = 3 is used.

On completion of the first call to E04UCF, the optimal variables are perturbed to produce the initial point for a second run in which the problem functions are defined by the subroutines OBJFN2 and CONFN2. To illustrate one of the finite-difference options in E04UCF, these routines are programmed so that the first six components of the objective gradient and the constant elements of the Jacobian matrix are not specified; hence, the option Derivative Level = 0 is chosen. During computation of the finite-difference intervals, the constant Jacobian elements are identified and set, and E04UCF automatically increases the derivative level to 2.

The second call to E04UCF illustrates the use of the Warm Start Level option to utilize the final active set, nonlinear multipliers and approximate Hessian from the first run. Note that Hessian = Yes was specified for the first run so that the array R would contain the Cholesky factor of the approximate Hessian of the Lagrangian.

The two calls to E04UCF illustrate the alternative methods of assigning default parameters. (There is no special significance in the order of these assignments; an options file may just as easily be used to modify parameters set by E04UEF.)

The results are typical of those obtained from E04UCF when solving well-behaved (non-trivial) nonlinear problems. The approximate Hessian and working set remain relatively well-conditioned. Similarly the penalty parameters remain small and approximately constant. The numerical results illustrate much of the theoretically predicted behaviour of a quasi-Newton SQP method. As \( x \) approaches the solution, only one minor iteration is performed per major iteration, and the Norm Gz and Norm C columns exhibit the fast linear convergence rate mentioned in Sections 5 and 6. Note that the constraint violations converge earlier than
the projected gradient. The final values of the project gradient norm and constraint norm reflect the limiting accuracy of the two quantities. It is possible to achieve almost full precision in the constraint norm but only half precision in the projected gradient norm. Note that the final accuracy in the nonlinear constraints is considerably better than the feasibility tolerance, because the constraint violations are being refined during the last few iterations while the algorithm is working to reduce the projected gradient norm. In this problem, the constraint values and Lagrange multipliers at the solution are 'well balanced', i.e., all the multipliers are approximately the same order of magnitude. The behaviour is typical of a well-scaled problem.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

Supply optional parameters to E04UCF from file

— nage.ht —
To supply optional parameters to E04UCF from an external file.

2. Specification

SUBROUTINE E04UDF (IOPTNS, INFORM)
    INTEGER    IOPTNS, INFORM

3. Description

E04UDF may be used to supply values for optional parameters to E04UCF. E04UDF reads an external file and each line of the file defines a single optional parameter. It is only necessary to supply values for those parameters whose values are to be different from their default values.

Each optional parameter is defined by a single character string of up to 72 characters, consisting of one or more items. The items associated with a given option must be separated by spaces, or equal signs (=). Alphabetic characters may be upper or lower case. The string

Print level = 1

is an example of a string used to set an optional parameter. For each option the string contains one or more of the following items:

(a) A mandatory keyword.

(b) A phrase that qualifies the keyword.

(c) A number that specifies an INTEGER or real value. Such numbers may be up to 16 contiguous characters in Fortran 77’s I, F, E or D formats, terminated by a space if this is not the last item on the line.

Blank strings and comments are ignored. A comment begins with an asterisk (*) and all subsequent characters in the string are regarded as part of the comment.

The file containing the options must start with begin and must finish with end An example of a valid options file is:

Begin * Example options file
  Print level =10
End

Normally each line of the file is printed as it is read, on the current advisory message unit (see X04ABF), but printing may be suppressed using the keyword nolist To suppress printing of begin,
nolist must be the first option supplied as in the file:

    Begin
    Nolist
    Print level = 10
    End

Printing will automatically be turned on again after a call to E04UCF and may be turned on again at any time by the user by using the keyword list.

Optional parameter settings are preserved following a call to E04UCF, and so the keyword defaults is provided to allow the user to reset all the optional parameters to their default values prior to a subsequent call to E04UCF.

A complete list of optional parameters, their abbreviations, synonyms and default values is given in Section 5.1 of the document for E04UCF.

4. References

None.

5. Parameters

1: IOPTNS -- INTEGER Input
   On entry: IOPTNS must be the unit number of the options file. Constraint: 0 <= IOPTNS <= 99.

2: INFORM -- INTEGER Output
   On exit: INFORM will be zero, if an options file with the current structure has been read. Otherwise INFORM will be positive. Positive values of INFORM indicate that an options file may not have been successfully read as follows:
   INFORM = 1
   IOPTNS is not in the range [0,99].
   INFORM = 2
   begin was found, but end-of-file was found before end was found.
   INFORM = 3
   end-of-file was found before begin was found.

6. Error Indicators and Warnings

If a line is not recognised as a valid option, then a warning message is output on the current advisory message unit (X04ABF).
7. Accuracy
Not applicable.

8. Further Comments
E04UEF may also be used to supply optional parameters to E04UCF.

9. Example
See the example for E04UCF.

Supply individual optional params to E04UCF

SUBROUTINE E04UEF (STRING)
3. Description

E04UEF may be used to supply values for optional parameters to E04UCF. It is only necessary to call E04UEF for those parameters whose values are to be different from their default values. One call to E04UEF sets one parameter value.

Each optional parameter is defined by a single character string of up to 72 characters, consisting of one or more items. The items associated with a given option must be separated by spaces, or equal signs (=). Alphabetic characters may be upper or lower case. The string

\[
\text{Print level} = 1
\]

is an example of a string used to set an optional parameter. For each option the string contains one or more of the following items:

(a) A mandatory keyword.

(b) A phrase that qualifies the keyword.

(c) A number that specifies an INTEGER or real value. Such numbers may be up to 16 contiguous characters in Fortran 77's I, F, E or D formats, terminated by a space if this is not the last item on the line.

Blank strings and comments are ignored. A comment begins with an asterisk (*) and all subsequent characters in the string are regarded as part of the comment.

Normally, each user-specified option is printed as it is defined, on the current advisory message unit (see X04ABF), but this printing may be suppressed using the keyword nolist. Thus the statement

\[
\text{CALL E04UEF ("Nolist")}
\]

suppresses printing of this and subsequent options. Printing will automatically be turned on again after a call to E04UCF, and may be turned on again at any time by the user, by using the keyword list.

Optional parameter settings are preserved following a call to E04UCF, and so the keyword defaults is provided to allow the user to reset all the optional parameters to their default values by the statement,
CALL E04UEF ("Defaults")

prior to a subsequent call to E04UCF.

A complete list of optional parameters, their abbreviations,
synonyms and default values is given in Section 5.1 of the
document for E04UCF.

4. References

None.

5. Parameters

1: STRING -- CHARACTER(*)
   Input
   On entry: STRING must be a single valid option string. See
   Section 3 above and Section 5.1 of the routine document for
   E04UCF. On entry: STRING must be a single valid option
   string. See Section 3 above and Section 5.1 of the routine
   document for E04UCF.

6. Error Indicators and Warnings

If the parameter STRING is not recognised as a valid option
string, then a warning message is output on the current advisory
message unit (X04ABF).

7. Accuracy

Not applicable.

8. Further Comments

E04UDF may also be used to supply optional parameters to E04UCF.

9. Example

See the example for E04UCF.
Estimates of elements of the variance-covariance matrix

--- nage.ht ---

\begin{page}{manpageXXe04ycf}{NAG Documentation: e04ycf}
\beginscroll
\begin{verbatim}
E04YCF(3NAG) Foundation Library (12/10/92) E04YCF(3NAG)

E04 -- Minimizing or Maximizing a Function
E04YCF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for
your implementation to check implementation-dependent details.
The symbol (*) after a NAG routine name denotes a routine that is
not included in the Foundation Library.

1. Purpose

E04YCF returns estimates of elements of the variance-covariance
matrix of the estimated regression coefficients for a nonlinear
least squares problem. The estimates are derived from the
Jacobian of the function \( f(x) \) at the solution.

This routine may be used following any one of the nonlinear
least-squares routines E04FCF(*), E04FDF, E04GBF(*), E04GCF,
E04GDF(*), E04GEF(*), E04HEF(*), E04HFF(*).

2. Specification

\begin{verbatim}
SUBROUTINE E04YCF (JOB, M, N, FSUMSQ, S, V, LV, CJ, WORK, IFAIL)
INTEGER JOB, M, N, LV, IFAIL
DOUBLE PRECISION FSUMSQ, S(N), V(LV,N), CJ(N), WORK(N)
\end{verbatim}

3. Description

E04YCF is intended for use when the nonlinear least-squares
\( T \)
function, \( F(x) = f(x)^T f(x) \), represents the goodness of fit of a
nonlinear model to observed data. The routine assumes that the
Hessian of \( F(x) \) at the solution, can be adequately approximated
\( T \)
by \( 2J^T J \), where \( J \) is the Jacobian of \( f(x) \) at the solution. The
estimated variance-covariance matrix $C$ is then given by

$$
C = \sigma^{-1} (J J)^T J J \text{ non-singular,}
$$

where $(\sigma)$ is the estimated variance of the residual at the solution, $x$, given by

$$
\sigma = \frac{F(x)}{m-n},
$$

$m$ being the number of observations and $n$ the number of variables.

The diagonal elements of $C$ are estimates of the variances of the estimated regression coefficients. See the Chapter Introduction E04 and Bard [1] and Wolberg [2] for further information on the use of $C$.

When $J J$ is singular then $C$ is taken to be

$$
C = \sigma^{-1} (J J)^T,
$$

where $(J J)^T$ is the pseudo-inverse of $J J$, but in this case the parameter IFAIL is returned as non-zero as a warning to the user that $J$ has linear dependencies in its columns. The assumed rank of $J$ can be obtained from IFAIL.

The routine can be used to find either the diagonal elements of $C$, or the elements of the $j$th column of $C$, or the whole of $C$.

E04YCF must be preceded by one of the nonlinear least-squares routines mentioned in Section 1, and requires the parameters FSUMSQ, $S$ and $V$ to be supplied by those routines. FSUMSQ is the residual sum of squares $F(x)$, and $S$ and $V$ contain the singular values and right singular vectors respectively in the singular value decomposition of $J$. $S$ and $V$ are returned directly by the comprehensive routines E04FCF(*), E04GBF(*), E04GDF(*) and E04HEF(*), but are returned as part of the workspace parameter $W$ from the easy-to-use routines E04FDF, E04GCF, E04GEF(*) and
E04HFF(*). In the case of E04FDF, S starts at \( W(\text{NS}) \), where

\[ \text{NS} = 6\times N + 2\times M + M\times N + 1 + \max(1, N\times(N-1)/2) \]

and in the cases of the remaining easy-to-use routines, S starts at \( W(\text{NS}) \), where

\[ \text{NS} = 7\times N + 2\times M + M\times N + N\times(N+1)/2 + 1 + \max(1, N\times(N-1)/2) \]

The parameter V starts immediately following the elements of S, so that V starts at \( W(\text{NV}) \), where

\[ \text{NV} = \text{NS} + N. \]

For all the easy-to-use routines the parameter LV must be supplied as N. Thus a call to E04YCF following E04FDF can be illustrated as

```fortran
CALL E04FDF (M, N, X, FSUMSQ, IW, LIW, W, LW, IFAIL)
NS = 6\times N + 2\times M + M\times N + 1 + \max((1, N\times(N-1))/2)
NV = NS + N
CALL E04YCF (JOB, M, N, FSUMSQ, W(NS), W(NV),
* N, CJ, WORK, IFAIL)
```

where the parameters M, N, FSUMSQ and the \( (n\times n) \) elements \( W(\text{NS}), W(\text{NS}+1), \ldots, W(\text{NV}+N\times N-1) \) must not be altered between the calls to E04FDF and E04YCF. The above illustration also holds for a call to E04YCF following a call to one of E04GCF, E04GEF(*), E04HFF(*) except that NS must be computed as

\[ NS = 7\times N + 2\times M + M\times N + (N\times(N+1))/2 + 1 + \max((1, N\times(N-1))/2) \]

4. References

5. Parameters

1: JOB -- INTEGER  
   On entry: which elements of C are returned as follows:
   
   \[ JOB = -1 \]
   The \( n \) by \( n \) symmetric matrix C is returned.

   \[ JOB = 0 \]
   The diagonal elements of C are returned.
JOB > 0

The elements of column JOB of C are returned.
Constraint: -1 <= JOB <= N.

2: M -- INTEGER  Input
   On entry: the number m of observations \( f(x) \).
   Constraint: M >= N.

3: N -- INTEGER  Input
   On entry: the number n of variables \( x \). Constraint: 1 <= N <= M.

4: FSUMSQ -- DOUBLE PRECISION  Input
   On entry: the sum of squares of the residuals, \( F(x) \), at the solution \( x \), as returned by the nonlinear least-squares routine. Constraint: FSUMSQ >= 0.0.

5: S(N) -- DOUBLE PRECISION array  Input
   On entry: the n singular values of the Jacobian as returned by the nonlinear least-squares routine. See Section 3 for information on supplying S following one of the easy-to-use routines.

6: V(LV,N) -- DOUBLE PRECISION array  Input/Output
   On entry: the n by n right-hand orthogonal matrix (the right singular vectors) of \( J \) as returned by the nonlinear least-squares routine. See Section 3 for information on supplying V following one of the easy-to-use routines. On exit: when JOB >= 0 then V is unchanged.

   When JOB = -1 then the leading n by n part of V is overwritten by the n by n matrix C. When E04YCF is called with JOB = -1 following an easy-to-use routine this means that C is returned, column by column, in the n elements of 2 W given by W(NV), W(NV+1), ..., W(NV+N-1). (See Section 3 for the definition of NV).

7: LV -- INTEGER  Input
   On entry: the first dimension of the array V as declared in the (sub)program from which E04YCF is called.
Chapter 22. NAG Library Routines

When \( V \) is passed in the workspace parameter \( W \) following one of the easy-to-use least-square routines, \( LV \) must be the value \( N \).

8: \( CJ(N) \) -- DOUBLE PRECISION array
   Output
   On exit: with \( JOB = 0 \), \( CJ \) returns the \( n \) diagonal elements of \( C \).
   With \( JOB = j>0 \), \( CJ \) returns the \( n \) elements of the \( j \)th column of \( C \).
   When \( JOB = -1 \), \( CJ \) is not referenced.

9: \( WORK(N) \) -- DOUBLE PRECISION array
   Workspace
   When \( JOB = -1 \) or 0 then \( WORK \) is used as internal workspace.
   When \( JOB > 0 \), \( WORK \) is not referenced.

10: \( IFAIL \) -- INTEGER
    Input/Output
    On entry: \( IFAIL \) must be set to 0, -1 or 1. Users who are unfamiliar with this parameter should refer to the Essential Introduction for details.
    On exit: \( IFAIL = 0 \) unless the routine detects an error or gives a warning (see Section 6).

For this routine, because the values of output parameters may be useful even if \( IFAIL /=0 \) on exit, users are recommended to set \( IFAIL \) to -1 before entry. It is then essential to test the value of \( IFAIL \) on exit. To suppress the output of an error message when soft failure occurs, set \( IFAIL \) to 1.

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

\( IFAIL= 1 \)
   On entry \( JOB < -1 \),
   or \( JOB > N \),
   or \( N < 1 \),
   or \( M < N \),
   or \( FSUMSQ < 0.0 \).

\( IFAIL= 2 \)
   The singular values are all zero, so that at the solution
the Jacobian matrix $J$ has rank 0.

IFAIL $> 2$
At the solution the Jacobian matrix contains linear, or near linear, dependencies amongst its columns. In this case the required elements of $C$ have still been computed based upon $J$ having an assumed rank given by $(IFAIL - 2)$. The rank is computed by regarding singular values $SV(j)$ that are not larger than $10^*\text{(epsilon)}*SV(1)$ as zero, where $(\text{epsilon})$ is the machine precision (see X02AJF(*)). Users who expect near linear dependencies at the solution and are happy with this tolerance in determining rank should call E04YCF with IFAIL = 1 in order to prevent termination by P01ABF(*). It is then essential to test the value of IFAIL on exit from E04YCF.

IFAIL Overflow
If overflow occurs then either an element of $C$ is very large, or the singular values or singular vectors have been incorrectly supplied.

7. Accuracy

The computed elements of $C$ will be the exact covariances corresponding to a closely neighbouring Jacobian matrix $J$.

8. Further Comments

When JOB $= -1$ the time taken by the routine is approximately $3$ proportional to $n$. When JOB $\geq 0$ the time taken by the routine is approximately proportional to $n^2$.

9. Example

To estimate the variance-covariance matrix $C$ for the least-squares estimates of $x_1$, $x_2$ and $x_3$ in the model

$$y = x_1 + \frac{1}{x_2 + x_3} t$$

using the 15 sets of data given in the following table:

<table>
<thead>
<tr>
<th>$y$</th>
<th>$t_1$</th>
<th>$t_2$</th>
<th>$t_3$</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.14</td>
<td>1.0</td>
<td>15.0</td>
<td>1.0</td>
</tr>
</tbody>
</table>
The program uses \((0.5,1.0,1.5)\) as the initial guess at the position of the minimum and computes the least-squares solution using E04FDF. See the routine document E04FDF for further information.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
1. Introduction

The F Chapters of the Library are concerned with linear algebra and cover a large area. This general introduction is intended to help users decide which particular F Chapter is relevant to their problem. There are F Chapters with the following titles:

F01 -- Matrix Factorizations
F02 -- Eigenvalues and Eigenvectors
F04 -- Simultaneous Linear Equations
F06 -- Linear Algebra Support Routines
F07 -- Linear Equations (LAPACK)

The principal problem areas addressed by the above Chapters are:

- Systems of linear equations
- Linear least-squares problems
- Eigenvalue and singular value problems

The solution of these problems usually involves several matrix operations, such as a matrix factorization followed by the solution of the factorized form, and the routines for these operations themselves utilize lower level support routines; typically routines from Chapter F06. Most users will not normally need to be concerned with these support routines.

NAG has been involved in a project, called LAPACK [1], to develop a linear algebra package for modern high-performance computers and some of the routines developed within that project are incorporated into the Library as Chapter F07. It should be emphasized that, while the LAPACK project has been concerned with high-performance computers, the routines do not compromise efficiency on conventional machines.

For background information on numerical algorithms for the solution of linear algebra problems see Golub and Van Loan [4]. For some problem areas the user has the choice of selecting a single routine to solve the problem, a so-called Black Box routine, or selecting more than one routine to solve the problem, such as a factorization routine followed by a solve routine, so-
called General Purpose routines. The following sections indicate which chapters are relevant to particular problem areas.

2. Linear Equations

The Black Box routines for solving linear equations of the form

\[ Ax=b \quad \text{and} \quad AX=B, \]

where \( A \) is an \( n \) by \( n \) real or complex, non-singular matrix, are to be found in Chapter F04. Such equations can also be solved by selecting a General Purpose factorization routine from Chapter F01 and combining it with a solve routine in Chapter F04, or by selecting a factorization and a solve routine from Chapter F07.

There are routines to cater for a variety of types of matrix, including general, symmetric or Hermitian, symmetric or Hermitian positive definite, tridiagonal, skyline and sparse matrices.

In order to select the appropriate routine, users are recommended to consult the F04 Chapter Introduction in the first instance.

3. Linear Least-squares

Routines for solving linear least-squares problems of the form

\[ \minimize_{x} r^T r, \quad \text{where} \quad r=b-Ax, \]

where \( A \) is an \( m \) by \( n \), possibly rank deficient, matrix are to be found in Chapter F04. Linear least-squares problems can also be solved by routines in the statistical Chapter G02.

In order to select the appropriate routine, users are recommended to consult the F04 Chapter Introduction in the first instance, but users with additional statistical requirements may prefer to consult the G02 Chapter Introduction.

4. Eigenvalue Problems and Singular Value Problems

Routines for solving standard matrix eigenvalue problems of the form

\[ Ax=(\lambda)x, \]

where \( A \) is an \( n \) by \( n \) real or complex matrix, and generalized matrix eigenvalue problems of the form
Ax=(\lambda)Bx

where \( \mathbf{B} \) is also an \( n \) by \( n \) matrix are to be found in Chapter F02.

There are routines to cater for various types of matrices, including general, symmetric or Hermitian and sparse matrices.

Similarly, the routines for finding singular values and/or singular vectors of an \( m \) by \( n \) real or complex matrix \( \mathbf{A} \) are to be found in Chapter F02.

In order to select the appropriate routine, users are recommended to consult the F02 Chapter Introduction in the first instance.

5. Matrix Factorizations

Routines for various sorts of matrix factorization are to be found in Chapters F01 and F07 together with associated transformation routines. In order to select the appropriate routine users are recommended to consult the F01 Chapter Introduction in the first instance.

6. Support Routines

Chapter F06 contains a variety of routines to perform elementary algebraic operations involving scalars, vectors and matrices, such as setting up a plane rotation, performing a dot product and computing a matrix-vector product. Chapter F06 contains routines that meet the specification of the BLAS (Basic Linear Algebra Subprograms) \([5, 3, 2]\). The routines in this chapter will not normally be required by the general user, but are intended for use by those who require to build specialist linear algebra modules. The BLAS are extensively used by other NAG Foundation Library routines.

Matrix Factorization

---

F01(3NAG)  Foundation Library (12/10/92)  F01(3NAG)
Chapter F01
Matrix Factorization

1. Scope of the Chapter

This chapter provides facilities for matrix factorizations and associated transformations.

2. Background to the Problems

An n by n matrix may be factorized as

\[ T \]
\[ A = PLUQ, \]

where L and U are respectively lower and upper triangular matrices, and P and Q are permutation matrices. This is called an LU factorization. For general dense matrices it is usual to choose Q=I and to then choose P to ensure that the factorization is numerically stable. For sparse matrices, judicious choice of P and Q ensures numerical stability as well as maintaining as much sparsity as possible in the factors L and U. The LU factorization is normally used in connection with the solution of the linear equations

\[ Ax = b, \]

whose solution, x, may then be obtained by solving in succession the simpler equations

\[ T \]
\[ Ly = Pb, \quad Uz = y, \quad x = Qz \]

the first by forward substitution and the second by backward substitution. Routines to perform this solution are to be found in Chapter F04.

When A is symmetric positive-definite then we can choose U=L and Q=P, to give the Cholesky factorization. This factorization is numerically stable without permutations, but in the sparse case the permutations can again be used to try to maintain sparsity. The Cholesky factorization is sometimes expressed as

\[ T \]
\[ A = P L D L P, \]

where D is a diagonal matrix with positive diagonal elements and
L is unit lower triangular.

The LU factorization can also be performed on rectangular matrices, but in this case it is more usual to perform a QR factorization. When A is an m by n (m\(\geq\)n) matrix this is given by

\[ A = QR, \]

where R is an n by n upper triangular matrix and Q is an orthogonal (unitary in the complex case) matrix.

3. Recommendations on Choice and Use of Routines

Routine F07ADF performs the LU factorization of a real m by n dense matrix.

The LU factorization of a sparse matrix is performed by routine F01BRF. Following the use of F01BRF, matrices with the same sparsity pattern may be factorized by routine F01BSF.

The Cholesky factorization of a real symmetric positive-definite dense matrix is performed by routine F07FDF.

Routine F01MAF performs the Cholesky factorization of a real symmetric positive-definite variable band (skyline) matrix, and a general sparse symmetric positive-definite matrix may be factorized using routine F01MAF.

The QR factorization of an m by n (m\(\geq\)n) matrix is performed by routine F01QCF in the real case, and F01RCF in the complex case. Following the use of F01QCF, operations with Q may be performed using routine F01QDF and some, or all, of the columns of Q may be formed using routine F01QEF. Routines F01RDF and F01REF perform the same tasks following the use of F01RCF.
definite matrix

\[ T \]

F01MCF LDL factorization of real symmetric positive-definite variable-bandwidth matrix

F01QCF QR factorization of real m by n matrix (m>=n)

F01QDF Operations with orthogonal matrices, compute QB or Q B after factorization by F01QCF

F01QEF Operations with orthogonal matrices, form columns of Q after factorization by F01QCF

F01RCF QR factorization of complex m by n matrix (m>=n)

F01RDF Operations with unitary matrices, compute QB or Q B after factorization by F01RCF

F01REF Operations with unitary matrices, form columns of Q after factorization by F01RCF

Factorizes a real sparse matrix

F01BRF(3NAG) Foundation Library (12/10/92) F01BRF(3NAG)

F01 -- Matrix Factorizations F01BRF
F01BRF -- NAG Foundation Library Routine Document
Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F01BRF factorizes a real sparse matrix. The routine either forms the LU factorization of a permutation of the entire matrix, or, optionally, first permutes the matrix to block lower triangular form and then only factorizes the diagonal blocks.

2. Specification

SUBROUTINE F01BRF (N, NZ, A, LICN, IRN, LIRN, ICN, PIVOT, IKEEP, IW, W, LBLOCK, GROW, ABORT, IDISP, IFAIL)

INTEGER N, NZ, LICN, IRN(LIRN), LIRN, ICN(LICN), IKEEP(5*N), IW(8*N), IDISP(10), IFAIL

DOUBLE PRECISION A(LICN), PIVOT, W(N)

LOGICAL LBLOCK, GROW, ABORT(4)

3. Description

Given a real sparse matrix A, this routine may be used to obtain the LU factorization of a permutation of A,

\[ PAQ = LU \]

where P and Q are permutation matrices, L is unit lower triangular and U is upper triangular. The routine uses a sparse variant of Gaussian elimination, and the pivotal strategy is designed to compromise between maintaining sparsity and controlling loss of accuracy through round-off.

Optionally the routine first permutes the matrix into block lower triangular form and then only factorizes the diagonal blocks. For some matrices this gives a considerable saving in storage and execution time.

Extensive data checks are made; duplicated non-zeros can be accumulated.

The factorization is intended to be used by F04AXF to solve \[ T \] sparse systems of linear equations \( Ax=b \) or \( A^x=b \). If several matrices of the same sparsity pattern are to be factorized, F01BSF should be used for the second and subsequent matrices.

The method is fully described by Duff [1].
4. References

5. Parameters

1: N -- INTEGER Input
   On entry: n, the order of the matrix A. Constraint: N > 0.

2: NZ -- INTEGER Input
   On entry: the number of non-zero elements in the matrix A.
   Constraint: NZ > 0.

3: A(LICN) -- DOUBLE PRECISION array Input/Output
   On entry: A(i), for i = 1,2,...,NZ must contain the non-zero elements of the sparse matrix A. They can be in any order since the routine will reorder them. On exit: the non-zero elements in the LU factorization. The array must not be changed by the user between a call of this routine and a call of F04AXF.

4: LICN -- INTEGER Input
   On entry: the dimension of the arrays A and ICN as declared in the (sub)program from which F01BRF is called. Since the factorization is returned in A and ICN, LICN should be large enough to accommodate this and should ordinarily be 2 to 4 times as large as NZ. Constraint: LICN >= NZ.

5: IRN(LIRN) -- INTEGER array Input/Output
   On entry: IRN(i), for i = 1,2,...,NZ must contain the row index of the non-zero element stored in A(i). On exit: the array is overwritten and is not needed for subsequent calls of F01BSF or F04AXF.

6: LIRN -- INTEGER Input
   On entry: the dimension of the array IRN as declared in the (sub)program from which F01BRF is called. It need not be as large as LICN; normally it will not need to be very much greater than NZ. Constraint: LIRN >= NZ.

7: ICN(LICN) -- INTEGER array Input/Output
   On entry: ICN(i), for i = 1,2,...,NZ must contain the column index of the non-zero element stored in A(i). On exit: the column indices of the non-zero elements in the
factorization. The array must not be changed by the user between a call of this routine and subsequent calls of F01BSF or F04AXF.

8: PIVOT -- DOUBLE PRECISION Input
On entry: PIVOT should have a value in the range 0.0 <= PIVOT <= 0.9999 and is used to control the choice of pivots. If PIVOT < 0.0, the value 0.0 is assumed, and if PIVOT > 0.9999, the value 0.9999 is assumed. When searching a row for a pivot, any element is excluded which is less than PIVOT times the largest of those elements in the row available as pivots. Thus decreasing PIVOT biases the algorithm to maintaining sparsity at the expense of stability. Suggested value: PIVOT = 0.1 has been found to work well on test examples.

9: IKEEP(5*N) -- INTEGER array Output
On exit: indexing information about the factorization. The array must not be changed by the user between a call of this routine and calls of F01BSF or F04AXF.

10: IW(8*N) -- INTEGER array Workspace

11: W(N) -- DOUBLE PRECISION array Output
On exit: if GROW = .TRUE., W(1) contains an estimate (an upper bound) of the increase in size of elements encountered during the factorization (see GROW); the rest of the array is used as workspace.
If GROW = .FALSE., the array is not used.

12: LBLOCK -- LOGICAL Input
On entry: if LBLOCK = .TRUE., the matrix is pre-ordered into block lower triangular form before the LU factorization is performed; otherwise the entire matrix is factorized. Suggested value: LBLOCK = .TRUE. unless the matrix is known to be irreducible.

13: GROW -- LOGICAL Input
On entry: if GROW = .TRUE., then on exit W(1) contains an estimate (an upper bound) of the increase in size of elements encountered during the factorization. If the matrix is well-scaled (see Section 8.2), then a high value for W(1) indicates that the LU factorization may be inaccurate and the user should be wary of the results and perhaps increase the parameter PIVOT for subsequent runs (see Section 7). Suggested value: GROW = .TRUE..

14: ABORT(4) -- LOGICAL array Input
On entry:
if ABORT(1) = .TRUE., the routine will exit immediately on detecting a structural singularity (one that depends on the pattern of non-zeros) and return IFAIL = 1; otherwise it will complete the factorization (see Section 8.3). 

If ABORT(2) = .TRUE., the routine will exit immediately on detecting a numerical singularity (one that depends on the numerical values) and return IFAIL = 2; otherwise it will complete the factorization (see Section 8.3). 

If ABORT(3) = .TRUE., the routine will exit immediately (with IFAIL = 5) when the arrays A and ICN are filled up by the previously factorized, active and unfactorized parts of the matrix; otherwise it continues so that better guidance on necessary array sizes can be given in IDISP(6) and IDISP(7), and will exit with IFAIL in the range 4 to 6. Note that there is always an immediate error exit if the array IRN is too small. 

If ABORT(4) = .TRUE., the routine exits immediately (with IFAIL = 13) if it finds duplicate elements in the input matrix. If ABORT(4) = .FALSE., the routine proceeds using a value equal to the sum of the duplicate elements. In either case details of each duplicate element are output on the current advisory message unit (see X04ABF), unless suppressed by the value of IFAIL on entry. 

Suggested values: 
ABORT(1) = .TRUE. 
ABORT(2) = .TRUE. 
ABORT(3) = .FALSE. 
ABORT(4) = .TRUE.. 

15: IDISP(10) -- INTEGER array 
Output 
On exit: IDISP is used to communicate information about the factorization to the user and also between a call of F01BRF and subsequent calls to F01BSF or F04AXF. 
IDISP(1) and IDISP(2), indicate the position in arrays A and ICN of the first and last elements in the LU factorization of the diagonal blocks. (IDISP(2) gives the number of non-zeros in the factorization.) 
IDISP(3) and IDISP(4), monitor the adequacy of }elbow
room’ in the arrays IRN and A/ICN respectively, by
giving the number of times that the data in these
arrays has been compressed during the factorization to
release more storage. If either IDISP(3) or IDISP(4)
is quite large (say greater than 10), it will probably
pay the user to increase the size of the corresponding
array(s) for subsequent runs. If either is very low or
zero, then the user can perhaps save storage by
reducing the size of the corresponding array(s).

IDISP(6), gives an upper bound on the rank of the
matrix.

IDISP(6) and IDISP(7), give the minimum size of arrays
IRN and A/ICN respectively which would enable a
successful run on an identical matrix (but some ’
elbow-room’ should be allowed - see Section 8).

IDISP(8) to (10), are only used if LBLOCK = .TRUE..

IDISP(8), gives the structural rank of the matrix.

IDISP(9), gives the number of diagonal blocks.

IDISP(10), gives the size of the largest diagonal
block.

IDISP(1) and IDISP(2), must not be changed by the user
between a call of F01BRF and subsequent calls to
F01BSF or F04AXF.

16: IFAIL -- INTEGER

For this routine, the normal use of IFAIL is extended to
control the printing of error and warning messages as well
as specifying hard or soft failure (see the Essential
Introduction).

Before entry, IFAIL must be set to a value with the decimal
expansion cba, where each of the decimal digits c, b and a
must have a value of 0 or 1.

a=0 specifies hard failure, otherwise soft failure;

b=0 suppresses error messages, otherwise error messages
will be printed (see Section 6);

c=0 suppresses warning messages, otherwise warning
messages will be printed (see Section 6).

The recommended value for inexperienced users is 110 (i.e.,
hard failure with all messages printed).
Unless the routine detects an error (see Section 6), IFAIL contains 0 on exit.

6. Error Indicators and Warnings

Errors detected by the routine:

For each error, an explanatory error message is output on the current error message unit (as defined by X04AAF), unless suppressed by the value of IFAIL on entry.

IFAIL=-2
Successful factorization of a numerically singular matrix (which may also be structurally singular) (see Section 8.3).

IFAIL=-1
Successful factorization of a structurally singular matrix (see Section 8.3).

IFAIL= 1
The matrix is structurally singular and the factorization has been abandoned (ABORT(1) was .TRUE. on entry).

IFAIL= 2
The matrix is numerically singular and the factorization has been abandoned (ABORT(2) was .TRUE. on entry).

IFAIL= 3
LIRN is too small: there is not enough space in the array IRN to continue the factorization. The user is recommended to try again with LIRN (and the length of IRN) equal to at least IDISP(6) + N/2.

IFAIL= 4
LICN is much too small: there is much too little space in the arrays A and ICN to continue the factorization.

IFAIL= 5
LICN is too small: there is not enough space in the arrays A and ICN to store the factorization. If ABORT(3) was .FALSE. on entry, the factorization has been completed but some of the LU factors have been discarded to create space, IDISP(7) then gives the minimum value of LICN (i.e., the minimum length of A and ICN) required for a successful factorization of the same matrix.

IFAIL= 6
LICN and LIRN are both too small: effectively this is a combination of IFAIL = 3 and IFAIL = 5 (with ABORT(3) = .FALSE.).
CHAPTER 22. NAG LIBRARY ROUTINES

IFAIL= 7
LICN is too small: there is not enough space in the arrays A and ICN for the permutation to block triangular form.

IFAIL= 8
On entry N <= 0.

IFAIL= 9
On entry NZ <= 0.

IFAIL= 10
On entry LICN < NZ.

IFAIL= 11
On entry LIRN < NZ.

IFAIL= 12
On entry an element of the input matrix has a row or column index (i.e., an element of IRN or ICN) outside the range 1 to N.

IFAIL= 13
Duplicate elements have been found in the input matrix and the factorization has been abandoned (ABORT(4) = .TRUE. on entry).

7. Accuracy

The factorization obtained is exact for a perturbed matrix whose (i,j)th element differs from a by less than 3(epsilon)(rho)mij

where (epsilon) is the machine precision, (rho) is the growth value returned in W(1) if GROW = .TRUE., and m the number of ij Gaussian elimination operations applied to element (i,j). The value of m is not greater than n and is usually much less. ijj

Small (rho) values therefore guarantee accurate results, but unfortunately large (rho) values may give a very pessimistic indication of accuracy.

8. Further Comments

8.1. Timing

The time required may be estimated very roughly from the number (tau) of non-zeros in the factorized form (output as IDISP(2)) and for this routine and its associates is
2
F01BRF: 5(tau) \(\times n\) units

2
F01BSF: (tau) \(\times n\) units

F04AXF: 2(tau) units

where our unit is the time for the inner loop of a full matrix code (e.g. solving a full set of equations takes about \(-n^{3}\) units). Note that the faster F01BSF time makes it well worthwhile to use this for a sequence of problems with the same pattern.

It should be appreciated that (tau) varies widely from problem to problem. For network problems it may be little greater than NZ, the number of non-zeros in A; for discretisation of 2-dimensional and 3-dimensional partial differential equations it may be about \(1.5n^{3/2}\) and \(-n^{2}\), respectively.

The time taken to find the block lower triangular form (LBLOCK = .TRUE.) is typically under 2\% of the overall time.

The overall time may be substantially increased if there is inadequate ‘elbow-room’ in the arrays A, IRN and ICN. When the sizes of the arrays are minimal (IDISP(6) and IDISP(7)) it can execute as much as three times slower. Values of IDISP(3) and IDISP(4) greater than about 10 indicate that it may be worthwhile to increase array sizes.

8.2. Scaling

The use of a relative pivot tolerance PIVOT essentially presupposes that the matrix is well-scaled, i.e., that the matrix elements are broadly comparable in size. Practical problems are often naturally well-scaled but particular care is needed for problems containing mixed types of variables (for example millimetres and neutron fluxes).

8.3. Singular and Rectangular Systems
It is envisaged that this routine will almost always be called for square non-singular matrices and that singularity indicates an error condition. However, even if the matrix is singular it is possible to complete the factorization. It is even possible for F04AXF to solve a set of equations whose matrix is singular provided the set is consistent.

Two forms of singularity are possible. If the matrix would be singular for any values of the non-zeros (e.g. if it has a whole row of zeros), then we say it is structurally singular, and continue only if ABORT(1) = .FALSE.. If the matrix is non-singular by virtue of the particular values of the non-zeros, then we say that it is numerically singular and continue only if ABORT(2) = .FALSE..

Rectangular matrices may be treated by setting N to the larger of the number of rows and numbers of columns and setting ABORT(1) =

Note: the soft failure option should be used (last digit of IFAIL = 1) if the user wishes to factorize singular matrices with ABORT (1) or ABORT(2) set to .FALSE..

8.4. Duplicated Non-zeros

The matrix A may consist of a sum of contributions from different sub-systems (for example finite elements). In such cases the user may rely on this routine to perform assembly, since duplicated elements are summed.

9. Example

To factorize the real sparse matrix:

\[
\begin{pmatrix}
5 & 0 & 0 & 0 & 0 \\
0 & 2 & -1 & 2 & 0 \\
0 & 0 & 3 & 0 & 0 \\
-2 & 0 & 0 & 1 & 1 \\
-1 & 0 & 0 & -1 & 2 \\
-1 & -1 & 0 & 0 & 6
\end{pmatrix}
\]

This example program simply prints out some information about the factorization as returned by F01BRF in W(1) and IDISP. Normally the call of F01BRF would be followed by a call of F04AXF (see Example for F04AXF).

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
Factorizes a real sparse matrix

--- nagf.ht ---

F01BSF(3NAG)  Foundation Library (12/10/92)  F01BSF(3NAG)

F01 -- Matrix Factorizations     F01BSF
F01BSF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F01BSF factorizes a real sparse matrix using the pivotal sequence previously obtained by F01BRF when a matrix of the same sparsity pattern was factorized.

2. Specification

```plaintext
SUBROUTINE F01BSF (N, NZ, A, LICN, IVECT, JVECT, ICN,
  1    IKEEP, IW, GROW, ETA, RPMIN, ABORT,
  2    IDISP, IFAIL)
  INTEGER N, NZ, LICN, IVECT(NZ), JVECT(NZ), ICN
  1    (LICN), IKEEP(5*N), IW(8*N), IDISP(2),
  2    IFAIL
  DOUBLE PRECISION A(LICN), W(N), ETA, RPMIN
  LOGICAL GROW, ABORT
```

3. Description

This routine accepts as input a real sparse matrix of the same
sparsity pattern as a matrix previously factorized by a call of F01BRF. It first applies to the matrix the same permutations as were used by F01BRF, both for permutation to block triangular form and for pivoting, and then performs Gaussian elimination to obtain the LU factorization of the diagonal blocks.

Extensive data checks are made; duplicated non-zeros can be accumulated.

The factorization is intended to be used by F04AXF to solve \( T \) sparse systems of linear equations \( Ax=b \) or \( A^T x=b \).

F01BSF is much faster than F01BRF and in some applications it is expected that there will be many calls of F01BSF for each call of F01BRF.

The method is fully described in Duff [1].

4. References

5. Parameters

1: N -- INTEGER Input
   On entry: \( n \), the order of the matrix \( A \). Constraint: \( N > 0 \).

2: NZ -- INTEGER Input
   On entry: the number of non-zeros in the matrix \( A \).
   Constraint: \( NZ > 0 \).

3: A(LICN) -- DOUBLE PRECISION array Input/Output
   On entry: \( A(i) \), for \( i = 1,2,\ldots,NZ \) must contain the non-zero elements of the sparse matrix \( A \). They can be in any order since the routine will reorder them. On exit: the non-zero elements in the factorization. The array must not be changed by the user between a call of this routine and a call of F04AXF.

4: LICN -- INTEGER Input
   On entry: the dimension of the arrays \( A \) and ICN as declared in the (sub)program from which F01BSF is called. It should have the same value as it had for F01BRF.
   Constraint: \( LICN >= NZ \).

5: IVECT(NZ) -- INTEGER array Input
6: JVECT(NZ) -- INTEGER array  
   Input  
   On entry: JVECT(i) and JVECT(i), for i = 1,2,...,NZ must 
   contain the row index and the column index respectively of 
   the non-zero element stored in A(i).

7: ICN(LICN) -- INTEGER array  
   Input  
   On entry: the same information as output by F01BRF. It must 
   not be changed by the user between a call of this routine 
   and a call of F04AXF.

8: IKEEP(5*N) -- INTEGER array  
   Input  
   On entry: the same indexing information about the 
   factorization as output from F01BRF. It must not be changed 
   between a call of this routine and a call of F04AXF.

9: IW(8*N) -- INTEGER array  
   Workspace

10: W(N) -- DOUBLE PRECISION array  
    Output  
    On exit: if GROW = .TRUE., W(1) contains an estimate (an 
    upper bound) of the increase in size of elements encountered 
    during the factorization (see GROW); the rest of the array 
    is used as workspace.

    If GROW = .FALSE., the array is not used.

11: GROW -- LOGICAL  
    Input  
    On entry: if GROW = .TRUE., then on exit W(1) contains an 
    estimate (an upper bound) of the increase in size of 
    elements encountered during the factorization. If the matrix 
    is well-scaled (see Section 8.2), then a high value for W(1) 
    indicates that the LU factorization may be inaccurate and 
    the user should be wary of the results and perhaps increase 
    the parameter PIVOT for subsequent runs (see Section 7).

12: ETA -- DOUBLE PRECISION  
    Input  
    On entry: the relative pivot threshold below which an error 
    diagnostic is provoked and IFAIL is set to 7. If ETA is 
    greater than 1.0, then no check on pivot size is made.

    Suggested value: ETA = 10.

13: RPMIN -- DOUBLE PRECISION  
    Output  
    On exit: if ETA is less than 1.0, then RPMIN gives the 
    smallest ratio of the pivot to the largest element in the 
    row of the corresponding upper triangular factor thus 
    monitoring the stability of the factorization. If RPMIN is 
    very small it may be advisable to perform a new 
    factorization using F01BRF.
14: ABORT -- LOGICAL
Input
On entry: if ABORT = .TRUE., the routine exits immediately
(with IFAIL = 8) if it finds duplicate elements in the input
matrix. If ABORT = .FALSE., the routine proceeds using a
value equal to the sum of the duplicate elements. In either
case details of each duplicate element are output on the
current advisory message unit (see X04ABF), unless
suppressed by the value of IFAIL on entry. Suggested value:
ABORT = .TRUE..

15: IDISP(2) -- INTEGER array
Input
On entry: IDISP(1) and IDISP(2) must be unchanged since the
previous call of F01BRF.

16: IFAIL -- INTEGER
Input/Output
For this routine, the normal use of IFAIL is extended to
control the printing of error and warning messages as well
as specifying hard or soft failure (see the Essential
Introduction).

Before entry, IFAIL must be set to a value with the decimal
expansion cba, where each of the decimal digits c, b and a
must have a value of 0 or 1.

a=0 specifies hard failure, otherwise soft failure;
b=0 suppresses error messages, otherwise error messages
will be printed (see Section 6);
c=0 suppresses warning messages, otherwise warning
messages will be printed (see Section 6).

The recommended value for inexperienced users is 110 (i.e.,
hard failure with all messages printed).

Unless the routine detects an error (see Section 6), IFAIL
contains 0 on exit.

6. Error Indicators and Warnings

Errors detected by the routine:

For each error, an explanatory error message is output on the
current error message unit (as defined by X04AAF), unless
suppressed by the value of IFAIL on entry.

IFAIL= 1
On entry N <= 0.

IFAIL= 2
On entry NZ <= 0.
IFAIL= 3
  On entry LICN < NZ.

IFAIL= 4
  On entry an element of the input matrix has a row or column
  index (i.e., an element of IVECT or JVECT) outside the range
  1 to N.

IFAIL= 5
  The input matrix is incompatible with the matrix factorized
  by the previous call of F01BRF (see Section 8).

IFAIL= 6
  The input matrix is numerically singular.

IFAIL= 7
  A very small pivot has been detected (see Section 5, ETA).
  The factorization has been completed but is potentially
  unstable.

IFAIL= 8
  Duplicate elements have been found in the input matrix and
  the factorization has been abandoned (ABORT = .TRUE. on
  entry).

7. Accuracy

The factorization obtained is exact for a perturbed matrix whose
(i,j)th element differs from a by less than 3(epsilon)(rho)m
    ij
where (epsilon) is the machine precision, (rho) is the growth
  ij
value returned in W(1) if GROW = .TRUE., and m the number of
  ij
Gaussian elimination operations applied to element (i,j).

If (rho) = W(1) is very large or RPMIN is very small, then a
fresh call of F01BRF is recommended.

8. Further Comments

If the user has a sequence of problems with the same sparsity
pattern then this routine is recommended after F01BRF has been
called for one such problem. It is typically 4 to 7 times faster
but is potentially unstable since the previous pivotal sequence
is used. Further details on timing are given in document F01BRF.

If growth estimation is performed (GROW = .TRUE.), then the time
increases by between 5% and 10%. Pivot size monitoring (ETA <= 1.
0) involves a similar overhead.
We normally expect this routine to be entered with a matrix having the same pattern of non-zeros as was earlier presented to F01BRF. However there is no record of this pattern, but rather a record of the pattern including all fill-ins. Therefore we permit additional non-zeros in positions corresponding to fill-ins.

If singular matrices are being treated then it is also required that the present matrix be sufficiently like the previous one for the same permutations to be suitable for factorization with the same set of zero pivots.

9. Example

To factorize the real sparse matrices

\[
\begin{pmatrix}
 5 & 0 & 0 & 0 & 0 \\
0 & 2 & -1 & 2 & 0 \\
0 & 0 & 3 & 0 & 0 \\
-2 & 0 & 0 & 1 & 1 \\
-1 & 0 & 0 & -1 & 2 \\
-1 & -1 & 0 & 0 & 6
\end{pmatrix}
\]

and

\[
\begin{pmatrix}
10 & 0 & 0 & 0 & 0 \\
0 & 12 & -3 & -1 & 0 \\
0 & 0 & 15 & 0 & 0 \\
-2 & 0 & 0 & 10 & -1 \\
-1 & 0 & 0 & -5 & 1 \\
-1 & -2 & 0 & 0 & 6
\end{pmatrix}
\]

This example program simply prints the values of $W(1)$ and RMIN returned by F01BSF. Normally the calls of F01BRF and F01BSF would be followed by calls of F04AXF.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

Incomplete Cholesky factorization

--- nagf.ht ---

\begin{page}{manpageXXf01maf}{NAG Documentation: f01maf}
\beginscroll
\begin{verbatim}
F01MAF(3NAG) Foundation Library (12/10/92) F01MAF(3NAG)

F01 -- Matrix Factorizations
F01MAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for
your implementation to check implementation-dependent details.
The symbol (*) after a NAG routine name denotes a routine that is
not included in the Foundation Library.

1. Purpose

F01MAF computes an incomplete Cholesky factorization of a real
sparse symmetric positive-definite matrix A.

2. Specification

SUBROUTINE F01MAF (N, NZ, A, LICN, IRN, LIRN, ICN, DROPTL,
1       DENSW, WKEEP, IKEEP, IWORK, ABORT,
2       INFORM, IFAIL)

INTEGER N, NZ, LICN, IRN(LIRN), LIRN, ICN(LICN),
       IKEEP(2*N), IWORK(6*N), INFORM(4), IFAIL

DOUBLE PRECISION A(LICN), DROPTL, DENSW, WKEEP(3*N)
LOGICAL ABORT(3)

3. Description

F01MAF computes an incomplete Cholesky factorization

\[ C = PLDL^T P, \quad WAW = C + E \]

for the sparse symmetric positive-definite matrix A, where P is a
permutation matrix, L is a unit lower triangular matrix, D is a
diagonal matrix with positive diagonal elements, E is an error
matrix representing elements dropped during the factorization and
diagonal elements that have been modified to ensure that C is
positive-definite, and $W$ is a diagonal matrix, chosen to make the diagonal elements of $WAW$ unity.

$W CW^{-1}$ is a pre-conditioning matrix for $A$, and the factorization of $C$ is intended to be used by F04MAF to solve systems of linear equations $Ax=b$.

The permutation matrix $P$ is chosen to reduce the amount of fill-in that occurs in $L$ and the user-supplied parameter DROPTL can also be used to control the amount of fill-in that occurs.

Full details on the factorization can be found in Munksgaard [1].

F01MAF is based on the Harwell Library routine MA31A.

4. References

5. Parameters

1: $N$ -- INTEGER Input
   On entry: $n$, the order of the matrix $A$. Constraint: $N \geq 1$.

2: $NZ$ -- INTEGER Input
   On entry: the number of non-zero elements in the upper triangular part of the matrix $A$, including the number of elements on the leading diagonal. Constraint: $NZ \geq N$.

3: $A(LICN)$ -- DOUBLE PRECISION array Input/Output
   On entry: the first $NZ$ elements of the array $A$ must contain the non-zero elements of the upper triangular part of the sparse positive-definite symmetric matrix $A$, including the elements on the leading diagonal. On exit: the first $(NZ-N)$ elements of $A$ contain the elements above the diagonal of the matrix $WAW$, where $W$ is a diagonal matrix whose $i$th diagonal element is $w = a_{ii}^{-1/2}$. These elements are returned in order by rows and the value returned in ICN($k$) gives the column index of the element returned in $A(k)$. The value $w$ is returned in the $i$th element of the array WKEEP. The remaining $LROW-NZ+N$ elements of $A$, where $LROW$ is the value returned in INFORM(1), return details of the factorization for use by F04MAF.

4: $LICN$ -- INTEGER Input
On entry:
the dimension of the array A as declared in the (sub)program from which F01MAF is called.
If fill-in is expected during the factorization, then a larger value of LICN will allow fewer elements to be dropped during the factorization, thus giving a more accurate factorization, which in turn will almost certainly mean that fewer iterations will be required by F04MAF. Constraint: LICN\geq2*NZ.

5: IRN(LIRN) -- INTEGER array Input/Output
On entry: IRN(k), for \(k = 1,2,\ldots,NZ\) must contain the row index of the non-zero element of the matrix A supplied in A (k). On exit: the first LCOL elements of IRN, where LCOL is the value returned in INFORM(2), return details of the factorization for use by F04MAF.

6: LIRN -- INTEGER Input
On entry:
the dimension of the array IRN as declared in the (sub)program from which F01MAF is called.
LIRN must be at least NZ, but, as with LICN, if fill-in is expected then a larger value of LIRN will allow a more accurate factorization. For this purpose LIRN should exceed NZ by the same amount that LICN exceeds 2*NZ. Constraint: LIRN \geq NZ.

7: ICN(LICN) -- INTEGER array Input/Output
On entry: ICN(k), for \(k = 1,2,\ldots,NZ\) must contain the column index of the non-zero element of the matrix A supplied in A (k). Thus \(a_{ij} = A(k)\), where \(i = \text{IRN}(k)\) and \(j = \text{ICN}(k)\). On exit: the first (NZ-N) elements of ICN give the column indices of the first (NZ-N) elements returned in A. The remaining LROW - NZ + N elements of ICN return details of the factorization for use by F04MAF.

8: DROPTL -- DOUBLE PRECISION Input/Output
On entry: a value in the range \([-1.0,1.0]\) to be used as a tolerance in deciding whether or not to drop elements during the factorization. At the kth pivot step the element \(a_{ij}\) is dropped if it would cause fill-in and if

\[
\frac{(k+1)}{(k)} \frac{|a_{ij}| < |\text{DROPTL}|}{a_{ii} a_{jj}}
\]

If DROPTL is supplied as negative, then it is not altered.
during the factorization and so is unchanged on exit, but if DROPTL is supplied as positive then it may be altered by the routine with the aim of obtaining an accurate factorization in the space available. If DROPTL is supplied as -1.0, then no fill-in will occur during the factorization; and if DROPTL is supplied as 0.0 then a complete factorization is performed. On exit: may be overwritten with the value used by the routine in order to obtain an accurate factorization in the space available, if DROPTL > 0.0 on entry.

9: DENSW -- DOUBLE PRECISION Input/Output
On entry: a value in the range [0.0,1.0] to be used in deciding whether or not to regard the active part of the matrix at the kth pivot step as being full. If the ratio of non-zero elements to the total number of elements is greater than or equal to DENSW, then the active part is regarded as full. If DENSW < 1.0, then the storage used is likely to increase compared to the case where DENSW = 0, but the execution time is likely to decrease. Suggested value: DENSW = 0.8. On exit: if on entry DENSW is not in the range [0.0,1.0], then it is set to 0.8. Otherwise it is unchanged.

10: WKEEP(3*N) -- DOUBLE PRECISION array Output
On exit: information which must be passed unchanged to F04MAF. The first N elements contain the values \( w_i \), for \( i = 1,2,...,n \), and the next N elements contain the diagonal elements of \( D \).

11: IKEEP(2*N) -- INTEGER array Output
On exit: information which must be passed unchanged to F04MAF.

12: IWORK(6*N) -- INTEGER array Workspace

13: ABORT(3) -- LOGICAL array Input
On entry:
if ABORT(1) = .TRUE., the routine will exit immediately on detecting duplicate elements and return IFAIL = 5. Otherwise when ABORT(1) = .FALSE., the calculations will continue using the sum of the duplicate entries. In either case details of the duplicate elements are output on the current advisory message unit (see X04ABF), unless suppressed by the value of IFAIL on entry.

If ABORT(2) = .TRUE., the routine will exit immediately on detecting a zero or negative pivot element and return IFAIL = 6. Otherwise when ABORT(2) = .FALSE., the zero or negative pivot element will be
modified to ensure positive-definiteness and a message will be printed on the current advisory message unit, unless suppressed by the value of IFAIL on entry.

If ABORT(3) = .TRUE., the routine will exit immediately if the arrays A and ICN have been filled up and return IFAIL = 7. Otherwise when ABORT(3) = .FALSE., the data in the arrays is compressed to release more storage and a message will be printed on the current advisory message unit, unless suppressed by the value of IFAIL on entry. If DROPTL is positive on entry, it may be modified in order to allow a factorization to be completed in the available space.

Suggested values:
ABORT(1) = .TRUE.,
ABORT(2) = .TRUE.,
ABORT(3) = .TRUE..

14: INFORM(4) -- INTEGER array
On exit:
INFORM(1) returns the number of elements of A and ICN that have been used by the routine. Thus at least the first INFORM(1) elements of A and of ICN must be supplied to F04MAF.

Similarly, INFORM(2) returns the number of elements of IRN that have been used by the routine and so at least the first INFORM(2) elements must be supplied to F04MAF.

INFORM(3) returns the number of entries supplied in A that corresponded to diagonal and duplicate elements. If no duplicate entries were found, then INFORM(3) will return the value of N.

INFORM(4) returns the value k of the pivot step from which the active matrix was regarded as full. INFORM must be passed unchanged to F04MAF.

15: IFAIL -- INTEGER
Input/Output
For this routine, the normal use of IFAIL is extended to control the printing of error and warning messages as well as specifying hard or soft failure (see the Essential Introduction).

Before entry, IFAIL must be set to a value with the decimal expansion cba, where each of the decimal digits c, b and a must have a value of 0 or 1.
a=0 specifies hard failure, otherwise soft failure;

b=0 suppresses error messages, otherwise error messages
will be printed (see Section 6);

c=0 suppresses warning messages, otherwise warning
messages will be printed (see Section 6).
The recommended value for inexperienced users is 110 (i.e.,
hard failure with all messages printed).

Unless the routine detects an error (see Section 6), IFAIL
contains 0 on exit.

6. Error Indicators and Warnings

Errors detected by the routine:

For each error, an explanatory error message is output on the
current error message unit (as defined by X04AAF), unless
suppressed by the value of IFAIL on entry.

IFAIL= 1
On entry N < 1,
    or    NZ < N,
    or    LIRN < NZ,
    or    LICN<2*NZ.

IFAIL= 2
One of the conditions 0 < IRN(k) <= ICN(k) <= N is not
satisfied so that A(k) is not in the upper triangle of the
matrix. No further computation is attempted.

IFAIL= 3
One of the diagonal elements of the matrix A is zero or
negative so that A is not positive-definite. No further
computation is attempted.

IFAIL= 4
The available space has been used and no further
compressions are possible. The user should either increase
DROPTL, or allocate more space to A, IRN and ICN.

For all the remaining values of IFAIL the computations will
continue in the case of soft failure, so that more than one
advisory message may be printed.

IFAIL= 5
Duplicate elements have been detected and ABORT(1) = .TRUE..

IFAIL= 6
A zero or negative pivot element has been detected during the factorization and ABORT(2) = .TRUE..

This should not happen if A is an M-matrix (see Munksgaard [1]), but may occur for other types of positive-definite matrix.

IFAIL= 7
The available space has been used and ABORT(3) = .TRUE..

7. Accuracy

The accuracy of the factorization will be determined by the size of the elements that are dropped and the size of the modifications made to the diagonal elements. If these sizes are small then the computed factors will correspond to a matrix close to A and the number of iterations required by F04MAF will be small. The more incomplete the factorization, the higher the number of iterations required by F04MAF.

8. Further Comments

The time taken by the routine will depend upon the sparsity pattern of the matrix and the number of fill-ins that occur during the factorization. At the very least the time taken can be expected to be roughly proportional to n(tau), where (tau) is the number of non-zeros.

The routine is intended for use with positive-definite matrices, but the user is warned that it will not necessarily detect non-positive-definiteness. Indeed the routine may return a factorization that can satisfactorily be used by F04MAF even when A is not positive-definite, but this should not be relied upon as F04MAF may not converge.

9. Example

The example program illustrates the use of F01MAF in conjunction with F04MAF to solve the 16 linear equations Ax=b, where

\[
\begin{pmatrix}
1 & z & z \\
(z & 1 & z \\
& z & 1 & z \\
& & z & 1 & 0 \\
& & & z & 1 \\
& & & & z \\
\end{pmatrix}
\]
The n by n matrix A arises in the solution of Laplace’s equation in a unit square, using a 5-point formula with a 6 by 6 discretisation, with unity on the boundaries.

The drop tolerance, DROPTL, is taken as 0.1, and the density factor, DENSW, is taken as 0.8. The value IFAIL = 111 is used so that advisory and error messages will be printed, but soft failure would occur if IFAIL were returned as non-zero.

A relative accuracy of about 0.0001 is requested in the solution from F04MAF, with a maximum of 50 iterations.

The example program for F02FJF illustrates the use of F01MAF and F04MAF in solving an eigenvalue problem.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
1. Purpose

F01MCF computes the Cholesky factorization of a real symmetric positive-definite variable-bandwidth matrix.

2. Specification

```
SUBROUTINE F01MCF (N, A, LAL, NROW, AL, D, IFAIL)
INTEGER N, LAL, NROW(N), IFAIL
DOUBLE PRECISION A(LAL), AL(LAL), D(N)
```

3. Description

This routine determines the unit lower triangular matrix L and the diagonal matrix D in the Cholesky factorization $A = LDL^T$ of a symmetric positive-definite variable-bandwidth matrix $A$ of order $n$. (Such a matrix is sometimes called a 'sky-line' matrix.)

The matrix $A$ is represented by the elements lying within the envelope of its lower triangular part, that is, between the first non-zero of each row and the diagonal (see Section 9 for an example). The width $NROW(i)$ of the $i$th row is the number of elements between the first non-zero element and the element on the diagonal, inclusive. Although, of course, any matrix possesses an envelope as defined, this routine is primarily intended for the factorization of symmetric positive-definite matrices with an average bandwidth which is small compared with $n$ (also see Section 8).

The method is based on the property that during Cholesky factorization there is no fill-in outside the envelope.
The determination of L and D is normally the first of two steps in the solution of the system of equations $Ax=b$. The remaining step, viz. the solution of $LDL^T x=b$ may be carried out using F04MCF.

4. References

5. Parameters

1:  $N$ -- INTEGER Input
   On entry: n, the order of the matrix $A$. Constraint: $N \geq 1$.

2:  $A(LAL)$ -- DOUBLE PRECISION array Input
   On entry: the elements within the envelope of the lower triangle of the positive-definite symmetric matrix $A$, taken in row by row order. The following code assigns the matrix elements within the envelope to the correct elements of the array:

   \[
   \begin{align*}
   K &= 0 \\
   \text{DO 20 I = 1, N} \\
   \text{DO 10 J = I-NROW(I)+1, I} \\
   K &= K + 1 \\
   A(K) &= \text{matrix (I,J)} \\
   \text{10 CONTINUE} \\
   \text{20 CONTINUE}
   \end{align*}
   \]
   See also Section 8.

3:  $LAL$ -- INTEGER Input
   On entry: the smaller of the dimensions of the arrays $A$ and $AL$ as declared in the calling (sub)program from which F01MCF is called. Constraint: $LAL \geq \sum NROW(i)$.

4:  $NROW(N)$ -- INTEGER array Input
   On entry: $NROW(i)$ must contain the width of row $i$ of the matrix $A$, i.e., the number of elements between the first (leftmost) non-zero element and the element on the diagonal, inclusive. Constraint: $1 \leq NROW(i) \leq i$, for $i=1,2,\ldots,n$.

5:  $AL(LAL)$ -- DOUBLE PRECISION array Output
On exit: the elements within the envelope of the lower triangular matrix $L$, taken in row by row order. The envelope of $L$ is identical to that of the lower triangle of $A$. The unit diagonal elements of $L$ are stored explicitly. See also Section 8.

6: D(N) -- DOUBLE PRECISION array  
On exit: the diagonal elements of the the diagonal matrix $D$. Note that the determinant of $A$ is equal to the product of these diagonal elements. If the value of the determinant is required it should not be determined by forming the product explicitly, because of the possibility of overflow or underflow. The logarithm of the determinant may safely be formed from the sum of the logarithms of the diagonal elements.

7: IFAIL -- INTEGER       
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL = 1
On entry $N < 1$,

or for some $i$, $NROW(i) < 1$ or $NROW(i) > i$,

or $LAL < NROW(1) + NROW(2) + ... + NROW(N)$.

IFAIL = 2
$A$ is not positive-definite, or this property has been destroyed by rounding errors. The factorization has not been completed.

IFAIL = 3
$A$ is not positive-definite, or this property has been destroyed by rounding errors. The factorization has been completed but may be very inaccurate (see Section 7).

7. Accuracy

If IFAIL = 0 on exit, then the computed $L$ and $D$ satisfy the relation $LDL = A + F$, where
CHAPTER 22. NAG LIBRARY ROUTINES

\[ \|F\| \leq km (\epsilon) \max_i a \]

and

\[ \|F\| \leq km (\epsilon) \|A\| , \]

where \( k \) is a constant of order unity, \( m \) is the largest value of \( NROW(i) \), and \( (\epsilon) \) is the machine precision. See Wilkinson and Reinsch \[2\], pp 25--27, 54--55. If IFAIL = 3 on exit, then the factorization has been completed although the matrix was not positive-definite. However the factorization may be very inaccurate and should be used only with great caution. For instance, if it is used to solve a set of equations \( Ax=b \) using F04MCF, the residual vector \( b-Ax \) should be checked.

8. Further Comments

The time taken by the routine is approximately proportional to the sum of squares of the values of \( NROW(i) \).

The distribution of row widths may be very non-uniform without undue loss of efficiency. Moreover, the routine has been designed to be as competitive as possible in speed with routines designed for full or uniformly banded matrices, when applied to such matrices.

Unless otherwise stated in the Users’ Note for your implementation, the routine may be called with the same actual array supplied for parameters \( A \) and \( AL \), in which case \( L \) overwrites the lower triangle of \( A \). However this is not standard Fortran 77 and may not work in all implementations.

9. Example

To obtain the Cholesky factorization of the symmetric matrix, whose lower triangle is:

\[
\begin{pmatrix}
1 \\
2 & 5 \\
0 & 3 & 13 \\
0 & 0 & 0 & 16 \\
5 & 14 & 18 & 8 & 55 \\
0 & 0 & 0 & 24 & 17 & 77
\end{pmatrix}
\]

For this matrix, the elements of \( NROW \) must be set to 1, 2, 2, 1,
22.5. NAGF.HT

5, 3, and the elements within the envelope must be supplied in row order as:

1, 2, 5, 3, 13, 16, 5, 14, 18, 8, 55, 24, 17, 77.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

QR factorization of the real m by n matrix A

SUBROUTINE F01QCF (M, N, A, LDA, ZETA, IFAIL)
INTEGER M, N, LDA, IFAIL

Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F01QCF finds the QR factorization of the real m by n matrix A, where m>=n.

2. Specification

       SUBROUTINE F01QCF (M, N, A, LDA, ZETA, IFAIL)
       INTEGER M, N, LDA, IFAIL
CHAPTER 22. NAG LIBRARY ROUTINES

DOUBLE PRECISION A(LDA,*), ZETA(*)

3. Description

The m by n matrix A is factorized as

\[
\begin{align*}
A &= Q(0) & \text{when } m>n, \\
A &= QR & \text{when } m=n,
\end{align*}
\]

where Q is an m by m orthogonal matrix and R is an n by n upper triangular matrix. The factorization is obtained by Householder’s method. The kth transformation matrix, Q, which is used to introduce zeros into the kth column of A is given in the form

\[
Q_k = \begin{pmatrix}
I & 0 \\
0 & T_k
\end{pmatrix},
\]

where

\[
T_k = I - uu^T, \quad u_k = (z_k), \quad z_k = (z_{k+1}, \ldots, z_m),
\]

(zeta) is a scalar and z is an (m-k) element vector. (zeta) and z are chosen to annihilate the elements below the triangular part of A.

The vector u is returned in the kth element of the array ZETA, and in the kth column of A, such that (zeta) is in ZETA(k) and the elements of z are in A(k+1,k),...,A(m,k). The elements of R are returned in the upper triangular part of A.

Q is given by

\[
Q = (Q_1 \ldots Q_n).
\]
n n-1 1

Good background descriptions to the QR factorization are given in Dongarra et al [1] and Golub and Van Loan [2], but note that this routine is not based upon LINPACK routine DQRDC.

4. References

5. Parameters

1: M -- INTEGER Input
   On entry: m, the number of rows of A. Constraint: M >= N.

2: N -- INTEGER Input
   On entry: n, the number of columns of A.
   When N = 0 then an immediate return is effected.
   Constraint: N >= 0.

3: A(LDA,*) -- DOUBLE PRECISION array Input/Output
   Note: the second dimension of the array A must be at least max(1,n).
   On entry: the leading m by n part of the array A must contain the matrix to be factorized. On exit: the n by n upper triangular part of A will contain the upper triangular matrix R and the m by n strictly lower triangular part of A will contain details of the factorization as described in Section 3.

4: LDA -- INTEGER Input
   On entry:
   the first dimension of the array A as declared in the (sub)program from which F01QCF is called.
   Constraint: LDA >= max(1,M).

5: ZETA(*) -- DOUBLE PRECISION array Output
   Note: the dimension of the array ZETA must be at least max (1,n)
   On exit: ZETA(k) contains the scalar (zeta) for the k th transformation. If T =I then ZETA(k)=0.0, otherwise ZETA(
contains \((zeta)\) as described in Section 3 and \((zeta)\) is always in the range \((1.0, \sqrt{2.0})\).

6: IFAIL -- INTEGER  
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL=-1  
On entry M < N,  
or N < 0,  
or LDA < M.

7. Accuracy

The computed factors \(Q\) and \(R\) satisfy the relation

\[
Q(R) = A + E,
\]

where

\[ ||E|| \leq c(\epsilon) ||A||,\]

and \(\epsilon\) is the machine precision (see X02AJF(*)), \(c\) is a modest function of \(m\) and \(n\) and \(||.||\) denotes the spectral (two) norm.

8. Further Comments

The approximate number of floating-point operations is given by

\[
2n (3m-n)/3.
\]

Following the use of this routine the operations
\[ B := Q^T B \quad \text{and} \quad B := Q B, \]

where \( B \) is an \( m \) by \( k \) matrix, can be performed by calls to F01QDF.

The operation \( B := Q^T B \) can be obtained by the call:

\[
\begin{align*}
\text{IFAIL} &= 0 \\
\text{CALL} &\text{ F01QDF('No transpose', 'Separate', M, N, A, LDA, ZETA,} \\
&\quad * \\
&\quad K, B, LDB, WORK, IFAIL)
\end{align*}
\]

\[ T \]

and \( B := Q B \) can be obtained by the call:

\[
\begin{align*}
\text{IFAIL} &= 0 \\
\text{CALL} &\text{ F01QDF('Transpose', 'Separate', M, N, A, LDA, ZETA,} \\
&\quad * \\
&\quad K, B, LDB, WORK, IFAIL)
\end{align*}
\]

In both cases WORK must be a \( k \) element array that is used as workspace. If \( B \) is a one-dimensional array (single column) then the parameter LDB can be replaced by \( M \). See F01QDF for further details.

The first \( k \) columns of the orthogonal matrix \( Q \) can either be obtained by setting \( B \) to the first \( k \) columns of the unit matrix and using the first of the above two calls, or by calling F01QEF, which overwrites the \( k \) columns of \( Q \) on the first \( k \) columns of the array \( A \). \( Q \) is obtained by the call:

\[
\begin{align*}
\text{CALL F01QEF('Separate', M, N, K, A, LDA, ZETA, WORK, IFAIL)}
\end{align*}
\]

As above WORK must be a \( k \) element array. If \( k \) is larger than \( N \), then \( A \) must have been declared to have at least \( k \) columns.

Operations involving the matrix \( R \) can readily be performed by the Level 2 BLAS routines DTRSV and DTRMV (see Chapter F06), but note that no test for near singularity of \( R \) is incorporated in DTRSV. If \( R \) is singular, or nearly singular then F02WUF(*) can be used to determine the singular value decomposition of \( R \).

9. Example

To obtain the QR factorization of the 5 by 3 matrix

\[
\begin{pmatrix}
2.0 & 2.5 & 2.5 \\
2.0 & 2.5 & 2.5 \\
1.6 & -0.4 & 2.8
\end{pmatrix}
\]

\[ A \]
The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

B := QB or B := Q^T B

---

F01QDF performs one of the transformations

T

B := QB or B := Q B,

where B is an \( m \) by \( n \) real matrix and \( Q \) is an \( m \) by \( m \) orthogonal matrix, given as the product of Householder transformation matrices.

This routine is intended for use following F01QCF or F01QFF(\#).
2. Specification

SUBROUTINE F01QDF (TRANS, WHERET, M, N, A, LDA, ZETA,  
1       NCOLB, B, LDB, WORK, IFAIL)  
INTEGER M, N, LDA, NCOLB, LDB, IFAIL  
DOUBLE PRECISION A(LDA,*), ZETA(*), B(LDB,*), WORK(*)  
CHARACTER*1 TRANS, WHERET

3. Description

Q is assumed to be given by

\[ Q = (Q \; Q \; \cdots \; Q), \]
\[ n \; n-1 \; 1 \]

Q being given in the form

\[ Q = \begin{pmatrix} I & 0 \\ 0 & T \\ k & k \end{pmatrix} \]

where

\[ T = I - uu^T \]
\[ k \]

(zeta) is a scalar and z is an \( (m-k) \) element vector. z must be
\[ k \]
supplied in the kth column of A in elements A(k+1,k),...,A(m,k)
and \( (zeta) \) must be supplied either in A(k,k) or in ZETA(k),
\[ k \]
depending upon the parameter WHERET.

To obtain Q explicitly B may be set to I and pre-multiplied by Q.
\[ T \]
This is more efficient than obtaining Q.

4. References

5. Parameters

1: TRANS -- CHARACTER*1  
   On entry: the operation to be performed as follows:
   TRANS = 'N' (No transpose)
   Perform the operation B:=QB.
   TRANS = 'T' or 'C' (Transpose)
   \( T \)
   Perform the operation B:=QB.
   Constraint: TRANS must be one of 'N', 'T' or 'C'.

2: WHERET -- CHARACTER*1  
   On entry: indicates where the elements of (zeta) are to be
   found as follows:
   WHERET = 'I' (In A)
   The elements of (zeta) are in A.
   WHERET = 'S' (Separate)
   The elements of (zeta) are separate from A, in ZETA.
   Constraint: WHERET must be one of 'I' or 'S'.

3: M -- INTEGER  
   On entry: m, the number of rows of A. Constraint: M >= N.

4: N -- INTEGER  
   On entry: n, the number of columns of A.
   When N = 0 then an immediate return is effected.
   Constraint: N >= 0.

5: A(LDA,*) -- DOUBLE PRECISION array  
   Note: the second dimension of the array A must be at least
   max(1,N).
   On entry: the leading m by n strictly lower triangular part
   of the array A must contain details of the matrix Q. In
   addition, when WHERET = 'I', then the diagonal elements of A
   must contain the elements of (zeta) as described under the
   argument ZETA below.

   When WHERET = 'S', the diagonal elements of the array A are
   referenced, since they are used temporarily to store the
   (zeta), but they contain their original values on return.
6: LDA -- INTEGER Input
On entry:
the first dimension of the array A as declared in the
(sub)program from which F01QDF is called.
Constraint: LDA >= max(1,M).

7: ZETA(*) -- DOUBLE PRECISION array Input
Note: when WHERET = 'S', the dimension of the array ZETA
must be greater than or equal to max(1,N). On entry: if
WHERET = 'S', the array ZETA must contain the elements of
(zeta). If ZETA(k) = 0.0 then T is assumed to be I
k
otherwise ZETA(k) is assumed to contain (zeta) .
k

When WHERET = 'I', ZETA is not referenced.

8: NCOLB -- INTEGER Input
On entry: ncolb, number of columns of B.
When NCOLB = 0 then an immediate return is effected.
Constraint: NCOLB >= 0.

9: B(LDB,*) -- DOUBLE PRECISION array Input/Output
Note: the second dimension of the array B must be at least
max(1,NCOLB).
On entry: the leading m by ncolb part of the array B must
contain the matrix to be transformed. On exit: B is
overwritten by the transformed matrix.

10: LDB -- INTEGER Input
On entry:
the first dimension of the array B as declared in the
(sub)program from which F01QDF is called.
Constraint: LDB >= max(1,M).

11: WORK(*) -- DOUBLE PRECISION array Workspace
Note: the dimension of the array WORK must be at least
max(1,NCOLB).

12: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not
familiar with this parameter (described in the Essential
Introduction) the recommended value is 0.
On exit: IFAIL = 0 unless the routine detects an error (see
Section 6).

6. Error Indicators and Warnings
Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL=-1
   On entry TRANS /= 'N', 'T' or 'C',
   or      WHERET /= 'I' or 'S',
   or      M < N,
   or      N < 0,
   or      LDA < M,
   or      NCOLB < 0,
   or      LDB < M.

7. Accuracy

Letting C denote the computed matrix Q B, C satisfies the relation

\[ QC = B + E, \]

where

\[ ||E|| \leq c(\varepsilon)||B||, \]

and (\varepsilon) the machine precision (see X02AJF(*)), c is a modest function of \( m \) and \( ||.|| \) denotes the spectral (two) norm.

An equivalent result holds for the computed matrix QB. See also Section 7 of F01QCF.

8. Further Comments

The approximate number of floating-point operations is given by

\[ 2n(2m-n)\text{ncolb}. \]

9. Example

To obtain the matrix Q B for the matrix B given by

\[
\begin{pmatrix}
1.1 & 0.00 \\
0.9 & 0.00 \\
0.6 & 1.32
\end{pmatrix}
\]
following the QR factorization of the 5 by 3 matrix A given by

\[
\begin{pmatrix}
2.0 & 2.5 & 2.5 \\
2.0 & 2.5 & 2.5 \\
1.6 & -0.4 & 2.8 \\
2.0 & -0.5 & 0.5 \\
1.2 & -0.3 & -2.9 \\
\end{pmatrix}
\]

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

First ncolq columns of the real m by m orthogonal matrix

--- nagf.ht ---

Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F01QEF returns the first ncolq columns of the real m by m orthogonal matrix Q, where Q is given as the product of
Householder transformation matrices.

This routine is intended for use following F01QCF or F01QFF(*).

2. Specification

```fortran
SUBROUTINE F01QEF (WHEREET, M, N, NCOLQ, A, LDA, ZETA, WORK, IFAIL)
    INTEGER M, N, NCOLQ, LDA, IFAIL
    DOUBLE PRECISION A(LDA,*), ZETA(*), WORK(*)
    CHARACTER*1 WHEREET
```

3. Description

Q is assumed to be given by

\[ Q = (Q \ldots Q ) , \]
\[
\begin{array}{llll}
  n & n-1 & \ldots & 1 \\
\end{array}
\]

Q being given in the form

\[ Q = (0 T ) \]

\[ k ( k) \]

where

\[ T = -I -u u \]

\[ k \quad k \quad k \]

\[ ((zeta) ) \]

\[ ( k) \]

\[ u = (z ) \]

\[ k \quad k \]

(zeta) is a scalar and z is an (m-k) element vector. z must be supplied in the kth column of A in elements A(k+1,k),...,A(m,k) and (zeta) must be supplied either in A(k,k) or in ZETA(k), depending upon the parameter WHEREET.

4. References

5. Parameters

1:  WHERET -- CHARACTER*1   Input
    On entry: indicates where the elements of (zeta) are to be
    found as follows:
    WHERET = 'I' (In A)
        The elements of (zeta) are in A.
    WHERET = 'S' (Separate)
        The elements of (zeta) are separate from A, in ZETA.
    Constraint: WHERET must be one of 'I' or 'S'.

2:  M -- INTEGER   Input
    On entry: m, the number of rows of A. Constraint: M >= N.

3:  N -- INTEGER   Input
    On entry: n, the number of columns of A. Constraint: N >= 0.

4:  NCOLQ -- INTEGER   Input
    On entry: ncolq, the required number of columns of Q.
    Constraint: 0 <= NCOLQ <= M.

    When NCOLQ = 0 then an immediate return is effected.

5:  A(LDA,*) -- DOUBLE PRECISION array   Input/Output
    Note: the second dimension of the array A must be at least
    max(1,N,NCOLQ).
    On entry: the leading m by n strictly lower triangular part
    of the array A must contain details of the matrix Q. In
    addition, when WHERET = 'I', then the diagonal elements of A
    must contain the elements of (zeta) as described under the
    argument ZETA below. On exit: the first NCOLQ columns of the
    array A are overwritten by the first NCOLQ columns of the m
    by m orthogonal matrix Q. When N = 0 then the first NCOLQ
    columns of A are overwritten by the first NCOLQ columns of
    the identity matrix.

6:  LDA -- INTEGER   Input
    On entry:
    the first dimension of the array A as declared in the
    (sub)program from which F01QEF is called.
    Constraint: LDA >= max(1,M).

7:  ZETA(*) -- DOUBLE PRECISION array   Input
    Note: the dimension of the array ZETA must be at least
max(1,N).
On entry: with WHERET = 'S', the array ZETA must contain the
elements of (zeta). If ZETA(k) = 0.0 then T is assumed to
be I, otherwise ZETA(k) is assumed to contain (zeta).

When WHERET = 'I', the array ZETA is not referenced.

8: WORK(*) -- DOUBLE PRECISION array Workspace
Note: the dimension of the array WORK must be at least
max(1,NCOLQ).

9: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not
familiar with this parameter (described in the Essential
Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see
Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL=-1
On entry WHERET /= 'I' or 'S',
or M < N,
or N < 0,
or NCOLQ < 0 or NCOLQ > M,
or LDA < M.

7. Accuracy

The computed matrix Q satisfies the relation

Q=P+E,

where P is an exactly orthogonal matrix and

||E||<=c(epsilon)

(epsilon) is the machine precision (see X02AJF(*)), c is a modest
function of \( m \) and \(||.||\) denotes the spectral (two) norm. See also Section 7 of F01QCF.

8. Further Comments

The approximate number of floating-point operations required is given by

\[
2^{-n}\frac{(3m-n)(2n\text{colq}-n) - n(n\text{colq}-n)}{3}, \quad n\text{colq}>n,
\]
\[
2^{2^{-n}}\frac{(3m-n\text{colq})}{3}, \quad n\text{colq}\leq n.
\]

9. Example

To obtain the 5 by 5 orthogonal matrix \( Q \) following the QR factorization of the 5 by 3 matrix \( A \) given by

\[
\begin{pmatrix}
2.0 & 2.5 & 2.5 \\
2.0 & 2.5 & 2.5 \\
1.6 & -0.4 & 2.8 \\
2.0 & -0.5 & 0.5 \\
1.2 & -0.3 & -2.9
\end{pmatrix}
\]

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
1. Purpose

F01RCF finds the QR factorization of the complex m by n matrix A, where m\(\geq n\).

2. Specification

```fortran
SUBROUTINE F01RCF (M, N, A, LDA, THETA, IFAIL)
INTEGER M, N, LDA, IFAIL
COMPLEX(KIND(1.0D0)) A(LDA,*), THETA(*)
```

3. Description

The m by n matrix A is factorized as

\[
A = \begin{cases} 
  Q(0) & \text{when } m > n, \\
  QR & \text{when } m = n,
\end{cases}
\]

where Q is an m by m unitary matrix and R is an n by n upper triangular matrix with real diagonal elements.

The factorization is obtained by Householder's method. The kth transformation matrix, Q, which is used to introduce zeros into the kth column of A is given in the form

\[
Q = \begin{pmatrix} 
  I & 0 \\
  0 & T
\end{pmatrix},
\]

where

\[
H = I - \gamma u u^T,
\]

and

\[
T = I - \gamma u u^T.
\]
(gamma) is a scalar for which Re (gamma) = 1.0, (zeta) is a real scalar and z is an (m-k) element vector. (gamma), (zeta) and z are chosen to annihilate the elements below the triangular part of A and to make the diagonal elements real.

The scalar (gamma) and the vector u are returned in the kth element of the array THETA and in the kth column of A, such that (theta), given by

\[
(\theta) = ((zeta), \text{Im}(\gamma)),
\]

is in THETA(k) and the elements of z are in a_{k+1,k}, a_{m,k}. The elements of R are returned in the upper triangular part of A.

Q is given by

\[
Q=(Q_{11} \quad \ldots \quad Q_{n,n-1}, Q_{n,n-1} \quad \ldots \quad Q_{n,n}),
\]

A good background description to the QR factorization is given in Dongarra et al [1], but note that this routine is not based upon LINPACK routine ZQRDC.

4. References

5. Parameters

1: M -- INTEGER Input
   On entry: m, the number of rows of A. Constraint: M >= N.

2: N -- INTEGER Input
On entry: n, the number of columns of A. Constraint: N >= 0.

When N = 0 then an immediate return is effected.

3: A(LDA,*): COMPLEX(KIND(1.0D0)) array Input/Output
Note: the second dimension of the array A must be at least max(1,N).
On entry: the leading m by n part of the array A must contain the matrix to be factorized. On exit: the n by n upper triangular part of A will contain the upper triangular matrix R, with the imaginary parts of the diagonal elements set to zero, and the m by n strictly lower triangular part of A will contain details of the factorization as described above.

4: LDA -- INTEGER Input
On entry: the first dimension of the array A as declared in the (sub)program from which F01RCF is called.
Constraint: LDA >= max(1,M).

5: THETA(*): COMPLEX(KIND(1.0D0)) array Output
Note: the dimension of the array THETA must be at least max(1,N).
On exit: the scalar (theta) for the kth transformation. If k
T =I then THETA(k) = 0.0; if
k
((alpha) 0)
T =(
0 I) Re(alpha)<0.0,
then THETA(k)=(alpha); otherwise THETA(k) contains THETA(k) as described in Section 3 and Re(THETA(k)) is always in the range (1.0, \sqrt{2.0}).

6: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:
If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL=-1
On entry M < N,
or N < 0,
or LDA < M.

7. Accuracy
The computed factors Q and R satisfy the relation

\[ Q(0) = A + E, \]

where

\[ ||E|| \leq c(\text{epsilon})||A||, \]

(\text{epsilon}) being the machine precision, c is a modest function of m and n and ||.|| denotes the spectral (two) norm.

8. Further Comments
The approximate number of real floating-point operations is given by
\[ 8n (3m-n)/3. \]

Following the use of this routine the operations

\[ B := QB \quad \text{and} \quad B := QB, \]

where B is an m by k matrix, can be performed by calls to F01RDF. The operation B := QB can be obtained by the call:

\[
\begin{align*}
\text{IFAIL} &= 0 \\
\text{CALL F01RDF('No conjugate', 'Separate', M, N, A, LDA, THETA, K, B, LDB, WORK, IFAIL)} \\
\end{align*}
\]

H
and B := QB can be obtained by the call:

\[
\begin{align*}
\text{IFAIL} &= 0 \\
\text{CALL F01RDF('Conjugate', 'Separate', M, N, A, LDA, THETA, K, B, LDB, WORK, IFAIL)} \\
\end{align*}
\]
In both cases WORK must be a k element array that is used as workspace. If B is a one-dimensional array (single column) then the parameter LDB can be replaced by M. See F01RDF for further details.

The first k columns of the unitary matrix Q can either be obtained by setting B to the first k columns of the unit matrix and using the first of the above two calls, or by calling F01REF, which overwrites the k columns of Q on the first k columns of the array A. Q is obtained by the call:

\[
\text{CALL F01REF}(\text{`Separate'}, M, N, K, A, LDA, THETA, WORK, IFAIL)
\]

As above, WORK must be a k element array. If k is larger than n, then A must have been declared to have at least k columns.

Operations involving the matrix R can readily be performed by the Level 2 BLAS routines ZTRSV and ZTRMV (see Chapter F06), but note that no test for near singularity of R is incorporated in ZTRSV. If R is singular, or nearly singular, then F02XUF(\*) can be used to determine the singular value decomposition of R.

9. Example

To obtain the QR factorization of the 5 by 3 matrix

\[
A = \begin{pmatrix}
0.5i & -0.5+1.5i & -1.0+1.0i \\
0.4+0.3i & 0.9+1.3i & 0.2+1.4i \\
0.4 & -0.4+0.4i & 1.8 \\
0.3-0.4i & 0.1+0.7i & 0.0 \\
-0.3i & 0.3+0.3i & 2.4i \\
\end{pmatrix}
\]

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

\[
B := QB \text{ or } B := Q^H B
\]

— nagf.lib —
22.5. NAGF.HT

F01RDF(3NAG) Foundation Library (12/10/92) F01RDF(3NAG)

F01 -- Matrix Factorizations
F01RDF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F01RDF performs one of the transformations

\[ H \]

\[ B := QB \text{ or } B := Q B, \]

where \( B \) is an \( m \times \text{ncolb} \) complex matrix and \( Q \) is an \( m \times m \) unitary matrix, given as the product of Householder transformation matrices.

This routine is intended for use following F01RCF or F01RFF(*).

2. Specification

\[
\text{SUBROUTINE F01RDF (TRANS, WHERET, M, N, A, LDA, THETA,}
\]
\[
\text{NCOLB, B, LDB, WORK, IFAIL)}
\]
\[
\text{INTEGER M, N, LDA, NCOLB, LDB, IFAIL}
\]
\[
\text{COMPLEX(KIND(1.0D0)) A(LDA,*), THETA(*), B(LDB,*), WORK(*))}
\]
\[
\text{CHARACTER*1 TRANS, WHERET}
\]

3. Description

The unitary matrix \( Q \) is assumed to be given by

\[ Q = (Q \ldots Q), \]
\[ n \ n-1 \ 1 \]

\( Q \) being given in the form

\[ k \]
(I 0)
Q = (0 T),
k ( k)

where

\[ H = \begin{pmatrix} \gamma & 0 \\ 0 & I \end{pmatrix} \]
\[ T = I - (\gamma) u u^T \]
\[ (\zeta) \]
\[ u = z \]
\[ k ( k \]

\((\gamma)\) is a scalar for which \(\text{Re}(\gamma) = 1.0\), \((\zeta)\) is a real scalar and \(z\) is an \((m-k)\) element vector.

\(z\) must be supplied in the \(k\)th column of \(A\) in elements
\[ a_{k+1,k}, \ldots, a_{m,k} \]

\((\theta) = (\zeta), \text{Im}(\gamma)\),
\[ k ( k \]

must be supplied either in \(a\) or in \(\text{THETA}(k)\), depending upon
\[ k ( k \]

the parameter \(\text{WHERE}T\).

To obtain \(Q\) explicitly \(B\) may be set to \(I\) and pre-multiplied by \(Q\).

\[ H \]

This is more efficient than obtaining \(Q\). Alternatively, \(\text{F01REF}\) may be used to obtain \(Q\) overwritten on \(A\).

4. References

5. Parameters

1: TRANS -- CHARACTER*1           Input
On entry: the operation to be performed as follows:
TRANS = 'N' (No transpose)
Perform the operation \(B := QB\).
TRANS = 'C' (Conjugate transpose)
Perform the operation $B := Q B$.
Constraint: TRANS must be one of 'N' or 'C'.

2: WHERE T -- CHARACTER*1
   On entry: the elements of (theta) are to be found as
   follows:
   WHERE T = 'I' (In A)
       The elements of (theta) are in A.
   WHERE T = 'S' (Separate)
       The elements of (theta) are separate from A, in THETA.
Constraint: WHERE T must be one of 'I' or 'S'.

3: M -- INTEGER
   On entry: m, the number of rows of A. Constraint: M >= N.

4: N -- INTEGER
   On entry: n, the number of columns of A. Constraint: N >= 0.
   When N = 0 then an immediate return is effected.

5: A(LDA,*) -- COMPLEX(KIND(1.0D)) array
   Note: the second dimension of the array A must be at least
   max(1,N).
   On entry: the leading m by n strictly lower triangular part
   of the array A must contain details of the matrix Q. In
   addition, when WHERE T = 'I', then the diagonal elements of A
   must contain the elements of (theta) as described under the
   argument THETA below.

   When WHERE T = 'S', then the diagonal elements of the array A
   are referenced, since they are used temporarily to store the
   (zeta), but they contain their original values on return.

6: LDA -- INTEGER
   On entry:
   the first dimension of the array A as declared in the
   (sub)program from which F01RDF is called.
   Constraint: LDA >= max(1,M).

7: THETA(*) -- COMPLEX(KIND(1.0D)) array
   Note: the dimension of the array THETA must be at least
   max(1,N).
   On entry: with WHERE T = 'S', the array THETA must contain
   the elements of (theta). If THETA(k)=0.0 then T is assumed
   to be I; if THETA(k)=(alpha), with Re(alpha)<0.0, then T
assumed to be of the form

\[
T = \begin{pmatrix}
(\alpha) & 0 \\
0 & 1
\end{pmatrix};
\]

otherwise THETA(\(k\)) is assumed to contain (theta) given by

\[
(\text{theta}) = ((\zeta), \text{Im}(\gamma)).
\]

When WHERE = 'I', the array THETA is not referenced, and may be dimensioned of length 1.

8: NCOLB -- INTEGER Input
On entry: ncolb, the number of columns of B. Constraint: NCOLB >= 0.
When NCOLB = 0 then an immediate return is effected.

9: B(LDB,*) -- COMPLEX(KIND(1.0D)) array Input/Output
Note: the second dimension of the array B must be at least max(1,NCOLB).
On entry: the leading m by ncolb part of the array B must contain the matrix to be transformed. On exit: B is overwritten by the transformed matrix.

10: LDB -- INTEGER Input
On entry: the first dimension of the array B as declared in the (sub)program from which F01RDF is called.
Constraint: LDB >= max(1,M).

11: WORK(*) -- COMPLEX(KIND(1.0D)) array Workspace
Note: the dimension of the array WORK must be at least max(1,NCOLB).

12: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).
22.5. NAGF.HT

IFAIL=-1
On entry TRANS /= 'N' or 'C',
or WHERET /= 'I' or 'S',
or M < N,
or N < 0,
or LDA < M,
or NCOLB < 0,
or LDB < M.

7. Accuracy

Letting C denote the computed matrix Q B, C satisfies the relation

\[ QC = B + E, \]

where

\[ ||E|| \leq c(\text{epsilon})||B||, \]

(epsilon) being the machine precision, c is a modest function of m and \( ||.|| \) denotes the spectral (two) norm. An equivalent result holds for the computed matrix QB. See also Section 7 of F01RCF.

8. Further Comments

The approximate number of real floating-point operations is given by \( 8n(2m-n)\text{ncolb} \).

9. Example

H To obtain the matrix Q B for the matrix B given by

\[
\begin{pmatrix}
-0.55+1.05i & 0.45+1.05i \\
0.49+0.93i & 1.09+0.13i \\
0.49+0.93i & 1.09+0.13i \\
0.39+0.23i & -0.39-0.23i \\
1.13+0.83i & -1.13+0.77i \\
\end{pmatrix}
\]

following the QR factorization of the 5 by 3 matrix A given by

\[
\begin{pmatrix}
0.5i & -0.5+1.5i & -1.0+1.0i \\
\end{pmatrix}
\]
The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

First ncolq columns of the complex m by m unitary matrix

— nagf.ht —

F01REF returns the first ncolq columns of the complex m by m unitary matrix Q, where Q is given as the product of Householder transformation matrices.

This routine is intended for use following F01RCF.

2. Specification
SUBROUTINE F01REF (WHERE1T, M, N, NCOLQ, A, LDA, THETA, WORK, IFAIL)
INTEGER M, N, NCOLQ, LDA, IFAIL
COMPLEX(KIND(1.0D0)) A(LDA,*), THETA(*), WORK(*)
CHARACTER*1 WHERE1T

3. Description

The unitary matrix Q is assumed to be given by

\[
Q = \begin{pmatrix}
I & 0 \\
0 & T
\end{pmatrix},
\]

\( \begin{pmatrix}
Q & Q & \cdots & Q \\
n & n-1 & & 1
\end{pmatrix}
\)

Q being given in the form

\[
(1 0 )
Q = (0 T ),
( \begin{array}{c}
k \\
\end{array})
\]

where

\[
T = I - (\gamma) u u ,
( \begin{array}{c}
k \\
\end{array})
( \begin{array}{c}
(\zeta) \\
( \begin{array}{c}
k \\
\end{array})
\end{array})
\]

\( (\gamma) \) is a scalar for which Re \((\gamma)\) =1.0, \( (\zeta) \) is a real scalar and \( Z \) is an \((m-k)\) element vector.

\( Z \) must be supplied in the \( k\)th column of A in elements

\( (\theta) = (\zeta) , Im (\gamma) \),

\( \begin{array}{c}
k \\
\end{array} \begin{array}{c}
m,k \\
\end{array} \)

must be supplied either in \( A \) or in THETA\((k)\) depending upon the parameter WHERE1T.
4. References

5. Parameters

1: WHERE -- CHARACTER*1 Input
On entry: the elements of (theta) are to be found as follows:
WHERE = 'I' (In A)
    The elements of (theta) are in A.
WHERE = 'S' (Separate)
    The elements of (theta) are separate from A, in THETA.
Constraint: WHERE must be one of 'I' or 'S'.

2: M -- INTEGER Input
On entry: m, the number of rows of A. Constraint: M >= N.

3: N -- INTEGER Input
On entry: n, the number of columns of A. Constraint: N >= 0.

4: NCOLQ -- INTEGER Input
On entry: ncolq, the required number of columns of Q.
Constraint: 0 <= NCOLQ <= M.
When NCOLQ = 0 then an immediate return is effected.

5: A(LDA,*) -- COMPLEX(KIND(1.0D)) array Input/Output
Note: the second dimension of the array A must be at least max(1,N,NCOLQ).
On entry: the leading m by n strictly lower triangular part of the array A must contain details of the matrix Q. In addition, when WHERE = 'I', then the diagonal elements of A must contain the elements of (theta) as described under the argument THETA below. On exit: the first NCOLQ columns of the array A are overwritten by the first NCOLQ columns of the m by m unitary matrix Q. When N = 0 then the first NCOLQ columns of A are overwritten by the first NCOLQ columns of the unit matrix.

6: LDA -- INTEGER Input
On entry: the first dimension of the array A as declared in the (sub)program from which F01REF is called.
Constraint: LDA >= max(1,M).

7: THETA(*) -- COMPLEX(KIND(1.0D)) array Input
Note: the dimension of the array THETA must be at least max(1,N).

On entry: if WHERET = 'S', the array THETA must contain the elements of (theta). If THETA(k)=0.0 then T is assumed to be I; if THETA(k)=(alpha), with Re(alpha)<0.0, then T is assumed to be of the form

$$\begin{pmatrix} \text{alpha} & 0 \\ 0 & 1 \end{pmatrix}$$

otherwise THETA(k) is assumed to contain (theta) given by

$$\begin{pmatrix} \zeta_k & \text{Im}(\gamma_k) \\ \gamma_k & \zeta_k \end{pmatrix}$$

When WHERET = 'I', the array THETA is not referenced.

8: WORK(*) -- COMPLEX(KIND(1.0D)) array Workspace

Note: the dimension of the array WORK must be at least max(1,NCOLQ).

9: IFAIL -- INTEGER Input/Output

On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL=-1

On entry WHERET /= 'I' or 'S',

or M < N,

or N < 0,

or NCOLQ < 0 or NCOLQ > M,

or LDA < M.

7. Accuracy
The computed matrix $Q$ satisfies the relation

$$Q = P + E,$$

where $P$ is an exactly unitary matrix and

$$||E|| \leq c(\text{epsilon}),$$

(\text{epsilon}) being the machine precision, $c$ is a modest function of $m$ and $|||.||||_2$ denotes the spectral (two) norm. See also Section 7 of F01RCF.

8. Further Comments

The approximate number of real floating-point operations required is given by

$$8 - n((3m-n)(2\text{ncolq}-n)-n(n\text{colq}-n)), \quad \text{ncolq} > n$$

$$3$$

$$8 2$$

$$- n\text{colq} (3m-\text{ncolq}), \quad \text{ncolq} \leq n$$

$$3$$

9. Example

To obtain the 5 by 5 unitary matrix $Q$ following the QR factorization of the 5 by 3 matrix $A$ given by

$$A = \begin{pmatrix}
0.5i & -0.5+1.5i & -1.0+1.4i \\
0.4+0.3i & 0.9+i.3i & 0.2+1.4i \\
0.4 & -0.4+0.4i & 1.8 \\
0.3-0.4i & 0.1+i.7i & 0.0 \\
-0.3i & 0.3+i.3i & 2.4i
\end{pmatrix}.$$
Eigenvalues and Eigenvectors

1. Scope of the Chapter

This chapter is concerned with computing

- eigenvalues and eigenvectors of a matrix
- eigenvalues and eigenvectors of generalized matrix eigenvalue problems
- singular values and singular vectors of a matrix.

2. Background to the Problems

2.1. Eigenvalue Problems

In the most usual form of eigenvalue problem we are given a square n by n matrix A and wish to compute \( \lambda \) (an eigenvalue) and \( x \neq 0 \) (an eigenvector) which satisfy the equation

\[ Ax = \lambda x \]

Such problems are called 'standard' eigenvalue problems in contrast to 'generalized' eigenvalue problems where we wish to satisfy the equation

\[ Ax = \lambda Bx \]

B also being a square n by n matrix.

Section 2.1.1 and Section 2.1.2 discuss, respectively, standard and generalized eigenvalue problems where the matrices involved
are dense; Section 2.1.3 discusses both types of problem in the case where A and B are sparse (and symmetric).

2.1.1. Standard eigenvalue problems

Some of the routines in this chapter find all the n eigenvalues, some find all the n eigensolutions (eigenvalues and corresponding eigenvectors), and some find a selected group of eigenvalues and/or eigenvectors. The matrix A may be:

(i) general (real or complex)

(ii) real symmetric, or

(iii) complex Hermitian (so that if \(a_{ij} = (\alpha) + i(\beta)\) then \(a_{ji} = (\alpha) - i(\beta)\)).

In all cases the computation starts with a similarity transformation \(S^{-1}AS = T\), where \(S\) is non-singular and is the product of fairly simple matrices, and \(T\) has an 'easier form' than \(A\) so that its eigensolutions are easily determined. The matrices \(A\) and \(T\), of course, have the same eigenvalues, and if \(y\) is an eigenvector of \(T\) then \(Sy\) is the corresponding eigenvector of \(A\).

In case (i) (general real or complex \(A\)), the selected form of \(T\) is an upper Hessenberg matrix (\(t = 0\) if \(i-j>1\)) and \(S\) is the product of \(n-2\) stabilised elementary transformation matrices. There is no easy method of computing selected eigenvalues of a Hessenberg matrix, so that all eigenvalues are always calculated. In the real case this computation is performed via the Francis QR algorithm with double shifts, and in the complex case by means of the LR algorithm. If the eigenvectors are required they are computed by back-substitution following the QR and LR algorithm.

In case (ii) (real and symmetric \(A\)) the selected simple form of \(T\) is a tridiagonal matrix (\(t = 0\) if \(|i-j|>1\)), and \(S\) is the product of \(n-2\) orthogonal Householder transformation matrices. If only selected eigenvalues are required, they are obtained by the method of bisection using the Sturm sequence property, and the corresponding eigenvectors of \(T\) are computed by inverse iteration. If all eigenvalues are required, they are computed from \(T\) via the QL algorithm (an adaptation of the QR algorithm), and the corresponding eigenvectors of \(T\) are the product of the transformations for the QL reduction. In all cases the
corresponding eigenvectors of \( A \) are recovered from the computation of \( x = Sy \).

In case (iii) (complex Hermitian \( A \)) analogous transformations as in case (ii) are used. \( T \) has complex elements in off-diagonal positions, but a simple diagonal similarity transformation is then used to produce a real tridiagonal form, after which the QL algorithm and succeeding methods described in the previous paragraph are used to complete the solution.

2.1.2. Generalized eigenvalue problems

Here we distinguish as a special case those problems in which both \( A \) and \( B \) are symmetric and \( B \) is positive-definite and well-conditioned with respect to inversion (i.e., all the eigenvalues of \( B \) are significantly greater than zero). Such problems can be satisfactorily treated by first reducing them to case (ii) of Section 2.1.1 and then using the methods described there to compute the eigensolutions. If \( B \) is factorized as \( LL \) (\( L \) lower triangular), then \( Ax = (\lambda) Bx \) is equivalent to the standard symmetric problem \( Ry = (\lambda)y \), where \( R = L^{-1} A (L) \) and \( y = L^{-1} x \). After finding an eigenvector \( y \) of \( R \), the required \( x \) is computed by back-substitution in \( y = L x \).

For generalized problems of the form \( Ax = (\lambda) Bx \) which do not fall into the special case, the QZ algorithm is provided.

In order to appreciate the domain in which this algorithm is appropriate we remark first that when \( B \) is non-singular the problem \( Ax = (\lambda) Bx \) is fully equivalent to the problem \\

\[
-B^{-1} A x = (\lambda)x
\]

both the eigenvalues and eigenvectors being the same. When \( A \) is non-singular \( Ax = (\lambda) Bx \) is equivalent to

\[
-(B^{-1} A) x = (\lambda)x
\]

the problem \( (A \ B) x = (\mu)x \); the eigenvalues (\( \mu \)) being the reciprocals of the required eigenvalues and the eigenvectors remaining the same. In theory then, provided at least one of the matrices \( A \) and \( B \) is non-singular, the generalized problem \( Ax = (\lambda) Bx \) could be solved via the standard problem \( Cx = (\lambda)x \) with an appropriate matrix \( C \), and as far as economy of effort is concerned this is quite satisfactory. However, in practice, for this reduction to be satisfactory from the standpoint of numerical stability, one requires more than the mere non-singularity of \( A \) or \( B \). It is necessary that \( B^{-1} A \) (or \( A^{-1} B \)) should not only exist but that \( B \) (or \( A \)) should be well-
conditioned with respect to inversion. The nearer $B$ (or $A$) is to
\[-1\quad -1\]
singularity the more unsatisfactory $B^{-1}A$ (or $A^{-1}B$) will be as a
vehicle for determining the required eigenvalues. Unfortunately
\[-1\quad -1\]
one cannot counter ill-conditioning in $B$ (or $A$) by computing $B^{-1}A$
(or $A^{-1}B$) accurately to single precision using iterative
refinement. Well-determined eigenvalues of the original
$Ax=(\lambda)Bx$ may be poorly determined even by the correctly
\[-1\quad -1\]
rounded version of $B^{-1}A$ (or $A^{-1}B$). The situation may in some
instances be saved by the observation that if $Ax=(\lambda)Bx$ then
$(A-kB)x=(((\lambda)-k)B)x$. Hence if $A-kB$ is non-singular we may
\[-1\quad -1\]
solve the standard problem $[(A-kB)^{-1}]Bx=(\mu)x$ and for numerical
stability we require only that $(A-kB)^{-1}$ be well-conditioned with
respect to inversion.

In practice one may well be in a situation where no $k$ is known
for which $(A-kB)^{-1}$ is well-conditioned with respect to inversion
and indeed $(A-kB)^{-1}$ may be singular for all $k$. The QZ algorithm is
designed to deal directly with the problem $Ax=(\lambda)Bx$ itself
and its performance is unaffected by singularity or near-
singularity of $A$, $B$ or $A-kB$.

2.1.3. Sparse symmetric problems

If the matrices $A$ and $B$ are large and sparse (i.e., only a small
proportion of the elements are non-zero), then the methods
described in the previous Section are unsuitable, because in
reducing the problem to a simpler form, much of the sparsity of
the problem would be lost; hence the computing time and the
storage required would be very large. Instead, for symmetric
problems, the method of simultaneous iteration may be used to
determine selected eigenvalues and the corresponding
eigenvectors. The routine provided has been designed to handle
both symmetric and generalized symmetric problems.

2.2. Singular Value Problems

The singular value decomposition of an $m$ by $n$ real matrix $A$ is
given by

\[
T
A=QDP,
\]

where $Q$ is an $m$ by $m$ orthogonal matrix, $P$ is an $n$ by $n$ orthogonal
matrix and $D$ is an $m$ by $n$ diagonal matrix with non-negative
diagonal elements. The first $k=\min(m,n)$ columns of $Q$ and $P$ are
the left- and right-hand singular vectors of A and the k diagonal elements of D are the singular values.

When A is complex then the singular value decomposition is given by

\[ A = QDP, \]

where Q and P are unitary, P denotes the complex conjugate of P and D is as above for the real case.

If the matrix A has column means of zero, then AP is the matrix of principal components of A and the singular values are the square roots of the sample variances of the observations with respect to the principal components. (See also Chapter G03.)

Routines are provided to return the singular values and vectors of a general real or complex matrix.

3. Recommendations on Choice and Use of Routines

3.1. General Discussion

There is one routine, F02FJF, which is designed for sparse symmetric eigenvalue problems, either standard or generalized. The remainder of the routines are designed for dense matrices.

3.2. Eigenvalue and Eigenvector Routines

These reduce the matrix A to a simpler form by a similarity transformation \( S^{-1}AS = T \) where T is an upper Hessenberg or tridiagonal matrix, compute the eigensolutions of T, and then recover the eigenvectors of A via the matrix S. The eigenvectors are normalised so that

\[ \sum_{r=1}^{n} |x_r|^2 = 1 \]

x being the rth component of the eigenvector x, and so that the rth element of largest modulus is real if x is complex. For problems of the type \( Ax = \lambda Bx \) with A and B symmetric and B positive-definite, the eigenvectors are normalised so that \( x^TBx = 1 \), x...
always being real for such problems.

3.3. Singular Value and Singular Vector Routines

These reduce the matrix $A$ to real bidiagonal form, $B$ say, by $T$ orthogonal transformations $Q A P = B$ in the real case, and by $H$ unitary transformations $Q A P = B$ in the complex case, and the singular values and vectors are computed via this bidiagonal form. The singular values are returned in descending order.

3.4. Decision Trees

(i) Eigenvalues and Eigenvectors

Please see figure in printed Reference Manual

(ii) Singular Values and Singular Vectors

Please see figure in printed Reference Manual

Eigenvalues and Eigenvectors

F02AAF All eigenvalues of real symmetric matrix

F02ABF All eigenvalues and eigenvectors of real symmetric matrix

F02ADF All eigenvalues of generalized real symmetric-definite eigenproblem

F02AEF All eigenvalues and eigenvectors of generalized real symmetric-definite eigenproblem

F02AFF All eigenvalues of real matrix

F02AGF All eigenvalues and eigenvectors of real matrix

F02AJF All eigenvalues of complex matrix

F02AKF All eigenvalues and eigenvectors of complex matrix

F02AWF All eigenvalues of complex Hermitian matrix
Calculates all the eigenvalues of a real symmetric matrix

F02AAF calculates all the eigenvalues of a real symmetric matrix.

---

F02AAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F02AAF calculates all the eigenvalues of a real symmetric matrix.
2. Specification

SUBROUTINE F02AAF (A, IA, N, R, E, IFAIL)
INTEGER IA, N, IFAIL
DOUBLE PRECISION A(IA,N), R(N), E(N)

3. Description

This routine reduces the real symmetric matrix A to a real symmetric tridiagonal matrix using Householder’s method. The eigenvalues of the tridiagonal matrix are then determined using the QL algorithm.

4. References

5. Parameters

1: A(IA,N) -- DOUBLE PRECISION array Input/Output
   On entry: the lower triangle of the n by n symmetric matrix A. The elements of the array above the diagonal need not be set. On exit: the elements of A below the diagonal are overwritten, and the rest of the array is unchanged.

2: IA -- INTEGER Input
   On entry: the first dimension of the array A as declared in the (sub)program from which F02AAF is called.
   Constraint: IA >= N.

3: N -- INTEGER Input
   On entry: n, the order of the matrix A.

4: R(N) -- DOUBLE PRECISION array Output
   On exit: the eigenvalues in ascending order.

5: E(N) -- DOUBLE PRECISION array Workspace

6: IFAIL -- INTEGER Input/Output
   On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
   On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings
Errors detected by the routine:

IFAIL= 1
   Failure in F02AVF(*) indicating that more than 30*N iterations are required to isolate all the eigenvalues.

7. Accuracy

The accuracy of the eigenvalues depends on the sensitivity of the matrix to rounding errors produced in tridiagonalisation. For a detailed error analysis see Wilkinson and Reinsch [1] pp 222 and 235.

8. Further Comments

The time taken by the routine is approximately proportional to n

9. Example

To calculate all the eigenvalues of the real symmetric matrix:

\begin{verbatim}
  ( 0.5  0.0  2.3 -2.6 )
  ( 0.0  0.5 -1.4 -0.7 )
  ( 2.3 -1.4  0.5  0.0 )
  (-2.6 -0.7  0.0  0.5 )
\end{verbatim}

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
1. Purpose

F02ABF calculates all the eigenvalues and eigenvectors of a real symmetric matrix.

2. Specification

```fortran
SUBROUTINE F02ABF (A, IA, N, R, V, IV, E, IFAIL)
INTEGER IA, N, IV, IFAIL
DOUBLE PRECISION A(IA,N), R(N), V(IV,N), E(N)
```

3. Description

This routine reduces the real symmetric matrix A to a real symmetric tridiagonal matrix by Householder's method. The eigenvalues and eigenvectors are calculated using the QL algorithm.

4. References

5. Parameters

1: A(IA,N) -- DOUBLE PRECISION array
   Input
   On entry: the lower triangle of the n by n symmetric matrix A. The elements of the array above the diagonal need not be set. See also Section 8.

2: IA -- INTEGER
   Input
   On entry: the first dimension of the array A as declared in the (sub)program from which F02ABF is called.
   Constraint: IA >= N.

3: N -- INTEGER
   Input
On entry: n, the order of the matrix A.

4: R(N) -- DOUBLE PRECISION array Output
On exit: the eigenvalues in ascending order.

5: V(IV,N) -- DOUBLE PRECISION array Output
On exit: the normalised eigenvectors, stored by columns;
the ith column corresponds to the ith eigenvalue. The
eigenvectors are normalised so that the sum of squares of
the elements is equal to 1.

6: IV -- INTEGER Input
On entry:
the first dimension of the array V as declared in the
(sub)program from which F02ABF is called.
Constraint: IV >= N.

7: E(N) -- DOUBLE PRECISION array Workspace

8: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not
familiar with this parameter (described in the Essential
Introduction) the recommended value is 0.
On exit: IFAIL = 0 unless the routine detects an error (see
Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IAFIL= 1
Failure in F02AMF(*) indicating that more than 30*N
iterations are required to isolate all the eigenvalues.

7. Accuracy

The eigenvectors are always accurately orthogonal but the
accuracy of the individual eigenvectors is dependent on their
inherent sensitivity to changes in the original matrix. For a
detailed error analysis see Wilkinson and Reinsch [1] pp 222 and
235.

8. Further Comments

The time taken by the routine is approximately proportional to n

Unless otherwise stated in the Users' Note for your
implementation, the routine may be called with the same actual
array supplied for parameters A and V, in which case the
eigenvectors will overwrite the original matrix. However this is
not standard Fortran 77, and may not work on all systems.

9. Example

To calculate all the eigenvalues and eigenvectors of the real
symmetric matrix:

\[
\begin{pmatrix}
0.5 & 0.0 & 2.3 & -2.6 \\
0.0 & 0.5 & -1.4 & -0.7 \\
2.3 & -1.4 & 0.5 & 0.0 \\
-2.6 & -0.7 & 0.0 & 0.5
\end{pmatrix}
\]

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.

\end{verbatim}
\end{scroll}
\end{page}

---

Calculates all the eigenvalues of \( Ax = \lambda Bx \)

--- nagf.ht ---

\begin{page}{manpageXXf02adf}{NAG Documentation: f02adf}
\beginscroll
\begin{verbatim}
F02ADF(3NAG) Foundation Library (12/10/92) F02ADF(3NAG)

F02 -- Eigenvalue and Eigenvectors
F02ADF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users’ Note for
your implementation to check implementation-dependent details.
The symbol (*) after a NAG routine name denotes a routine that is
not included in the Foundation Library.

1. Purpose
F02ADF calculates all the eigenvalues of \( Ax = (\lambda)Bx \), where \( A \) is a real symmetric matrix and \( B \) is a real symmetric positive-definite matrix.

2. Specification

```fortran
SUBROUTINE F02ADF (A, IA, B, IB, N, R, DE, IFAIL)
   INTEGER IA, IB, N, IFAIL
   DOUBLE PRECISION A(IA,N), B(IB,N), R(N), DE(N)
```

3. Description

The problem is reduced to the standard symmetric eigenproblem using Cholesky's method to decompose \( B \) into triangular matrices, \( B = LL^T \), where \( L \) is lower triangular. Then \( Ax = (\lambda)Bx \) implies 
\[
-1^{-T} T L (L x) = (\lambda)(L x);
\]

hence the eigenvalues of \( Ax = (\lambda)Bx \) are those of \( Py = (\lambda)y \) where \( P \) is the symmetric matrix \( -1^{-T} T L AL \). Householder's method is used to tridiagonalise the matrix \( P \) and the eigenvalues are then found using the QL algorithm.

4. References

5. Parameters

1: \( A(IA,N) \) -- DOUBLE PRECISION array Input/Output
   On entry: the upper triangle of the \( n \) by \( n \) symmetric matrix \( A \). The elements of the array below the diagonal need not be set. On exit: the lower triangle of the array is overwritten. The rest of the array is unchanged.

2: \( IA \) -- INTEGER Input
   On entry: the first dimension of the array \( A \) as declared in the (sub)program from which F02ADF is called.
   Constraint: \( IA \geq N \).

3: \( B(IB,N) \) -- DOUBLE PRECISION array Input/Output
   On entry: the upper triangle of the \( n \) by \( n \) symmetric positive-definite matrix \( B \). The elements of the array below the diagonal need not be set. On exit: the elements below the diagonal are overwritten. The rest of the array is unchanged.
4: IB -- INTEGER Input
   On entry: the first dimension of the array B as declared in the
   (sub)program from which F02ADF is called.
   Constraint: IB >= N.

5: N -- INTEGER Input
   On entry: n, the order of the matrices A and B.

6: R(N) -- DOUBLE PRECISION array Output
   On exit: the eigenvalues in ascending order.

7: DE(N) -- DOUBLE PRECISION array Workspace

8: IFAIL -- INTEGER Input/Output
   On entry: IFAIL must be set to 0, -1 or 1. For users not
   familiar with this parameter (described in the Essential
   Introduction) the recommended value is 0.
   On exit: IFAIL = 0 unless the routine detects an error (see
   Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
   Failure in F01AEF(*); the matrix B is not positive-definite
   possibly due to rounding errors.

IFAIL= 2
   Failure in F02AVF(*), more than 30*N iterations are required
   to isolate all the eigenvalues.

7. Accuracy

In general this routine is very accurate. However, if B is ill-
conditioned with respect to inversion, the eigenvalues could be
inaccurately determined. For a detailed error analysis see

8. Further Comments

The time taken by the routine is approximately proportional to n

9. Example

To calculate all the eigenvalues of the general symmetric
eigenproblem $Ax = \lambda Bx$ where $A$ is the symmetric matrix:

$$
\begin{pmatrix}
0.5 & 1.5 & 6.6 & 4.8 \\
1.5 & 6.5 & 16.2 & 8.6 \\
6.6 & 16.2 & 37.6 & 9.8 \\
4.8 & 8.6 & 9.8 & -17.1
\end{pmatrix}
$$

and $B$ is the symmetric positive-definite matrix:

$$
\begin{pmatrix}
1 & 3 & 4 & 1 \\
3 & 13 & 16 & 11 \\
4 & 16 & 24 & 18 \\
1 & 11 & 18 & 27
\end{pmatrix}
$$

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

---

**Eigenvalues and eigenvectors of $Ax = \lambda Bx$**

--- nagf.ht ---

Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose
F02AEF calculates all the eigenvalues and eigenvectors of 
$Ax = \lambda Bx$, where $A$ is a real symmetric matrix and $B$ is a 
real symmetric positive-definite matrix.

2. Specification

```fortran
SUBROUTINE F02AEF (A, IA, B, IB, N, R, V, IV, DL, E, IFAIL)
INTEGER IA, IB, N, IV, IFAIL
DOUBLE PRECISION A(IA,N), B(IB,N), R(N), V(IV,N), DL(N), E
1 (N)
```

3. Description

The problem is reduced to the standard symmetric eigenproblem 
using Cholesky’s method to decompose $B$ into triangular matrices 
$T$
$B = LL^T$, where $L$ is lower triangular. Then $Ax = \lambda Bx$ implies 
$-1 -T T$
$(L AL )^T (L x) = (\lambda)(L x)$; hence the eigenvalues of 
$-1 -T$
$Ax = (\lambda) Bx$ are those of $P y = (\lambda)y$, where $P$ is the symmetric 
$-1 -T$
matrix $L AL^T$. Householder’s method is used to tridiagonalize 
the matrix $P$ and the eigenvalues are found using the QL 
algorithm. An eigenvector $z$ of the derived problem is related to 
$T$
an eigenvector $x$ of the original problem by $z = L x$. The 
eigenvectors $z$ are determined using the QL algorithm and are 
$T$
normalised so that $z z^T = 1$; the eigenvectors of the original 
$T$
problem are then determined by solving $L x = z$, and are normalised 
$T$
so that $x Bx = 1$.

4. References

5. Parameters

1: A(IA,N) -- DOUBLE PRECISION array

On entry: the upper triangle of the $n$ by $n$ symmetric matrix 
$A$. The elements of the array below the diagonal need not be 
set. On exit: the lower triangle of the array is 
overwritten. The rest of the array is unchanged. See also 
Section 8.
2: IA -- INTEGER
   On entry: the first dimension of the array A as declared in the
   (sub)program from which F02AEF is called.
   Constraint: IA >= N.

3: B(IB,N) -- DOUBLE PRECISION array
   On entry: the upper triangle of the n by n symmetric
   positive-definite matrix B. The elements of the array below
   the diagonal need not be set. On exit: the elements below
   the diagonal are overwritten. The rest of the array is
   unchanged.

4: IB -- INTEGER
   On entry: the first dimension of the array B as declared in the
   (sub)program from which F02AEF is called.
   Constraint: IB >= N.

5: N -- INTEGER
   On entry: n, the order of the matrices A and B.

6: R(N) -- DOUBLE PRECISION array
   On exit: the eigenvalues in ascending order.

7: V(IV,N) -- DOUBLE PRECISION array
   On exit: the normalised eigenvectors, stored by columns;
   the ith column corresponds to the ith eigenvalue. The
   eigenvectors x are normalised so that x B x = 1. See also
   Section 8.

8: IV -- INTEGER
   On entry: the first dimension of the array V as declared in the
   (sub)program from which F02AEF is called.
   Constraint: IV >= N.

9: DL(N) -- DOUBLE PRECISION array

10: E(N) -- DOUBLE PRECISION array

11: IFAIL -- INTEGER
   On entry: IFAIL must be set to 0, -1 or 1. For users not
   familiar with this parameter (described in the Essential
   Introduction) the recommended value is 0.
   On exit: IFAIL = 0 unless the routine detects an error (see
   Section 6).

6. Error Indicators and Warnings
Errors detected by the routine:

IFAIL = 1
Failure in F01AEF(*); the matrix B is not positive-definite, possibly due to rounding errors.

IFAIL = 2
Failure in F02AMF(*); more than 30*N iterations are required to isolate all the eigenvalues.

7. Accuracy

In general this routine is very accurate. However, if B is ill-conditioned with respect to inversion, the eigenvectors could be inaccurately determined. For a detailed error analysis see Wilkinson and Reinsch [1] pp 310, 222 and 235.

8. Further Comments

The time taken by the routine is approximately proportional to $n^3$.

Unless otherwise stated in the Users' Note for your implementation, the routine may be called with the same actual array supplied for parameters A and V, in which case the eigenvectors will overwrite the original matrix A. However this is not standard Fortran 77, and may not work on all systems.

9. Example

To calculate all the eigenvalues and eigenvectors of the general symmetric eigenproblem $Ax = \lambda Bx$ where A is the symmetric matrix:

\[
\begin{pmatrix}
0.5 & 1.5 & 6.6 & 4.8 \\
1.5 & 6.5 & 16.2 & 8.6 \\
6.6 & 16.2 & 37.6 & 9.8 \\
4.8 & 8.6 & 9.8 & -17.1
\end{pmatrix}
\]

and B is the symmetric positive-definite matrix:

\[
\begin{pmatrix}
1 & 3 & 4 & 1 \\
3 & 13 & 16 & 11 \\
4 & 16 & 24 & 18 \\
1 & 11 & 18 & 27
\end{pmatrix}
\]

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
Calculates all the eigenvalues of a real unsymmetric matrix

---

F02 -- Eigenvalue and Eigenvectors

F02AFF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details.

The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F02AFF calculates all the eigenvalues of a real unsymmetric matrix.

2. Specification

```fortran
SUBROUTINE F02AFF (A, IA, N, RR, RI, INTGER, IFAIL)
INTEGER IA, N, INTGER(N), IFAIL
DOUBLE PRECISION A(IA,N), RR(N), RI(N)
```

3. Description

The matrix A is first balanced and then reduced to upper Hessenberg form using stabilised elementary similarity transformations. The eigenvalues are then found using the QR algorithm for real Hessenberg matrices.
4. References

5. Parameters

1: A(IA,N) -- DOUBLE PRECISION array Input/Output
   On entry: the n by n matrix A. On exit: the array is overwritten.

2: IA -- INTEGER Input
   On entry: the dimension of the array A as declared in the (sub)program from which F02AFF is called.
   Constraint: IA \geq N.

3: N -- INTEGER Input
   On entry: n, the order of the matrix A.

4: RR(N) -- DOUBLE PRECISION array Output
   On exit: the real parts of the eigenvalues.

5: RI(N) -- DOUBLE PRECISION array Output
   On exit: the imaginary parts of the eigenvalues.

6: INTEGER(N) -- INTEGER array Output
   On exit: INTEGER(i) contains the number of iterations used to find the ith eigenvalue. If INTEGER(i) is negative, the ith eigenvalue is the second of a pair found simultaneously.

   Note that the eigenvalues are found in reverse order, starting with the nth.

7: IFAIL -- INTEGER Input/Output
   On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
   On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
   More than 30*N iterations are required to isolate all the eigenvalues.
7. Accuracy

The accuracy of the results depends on the original matrix and the multiplicity of the roots. For a detailed error analysis see Wilkinson and Reinsch [1] pp 352 and 367.

8. Further Comments

The time taken by the routine is approximately proportional to n

9. Example

To calculate all the eigenvalues of the real matrix:

\[
\begin{pmatrix}
1.5 & 0.1 & 4.5 & -1.5 \\
-22.5 & 3.5 & 12.5 & -2.5 \\
-2.5 & 0.3 & 4.5 & -2.5 \\
-2.5 & 0.1 & 4.5 & 2.5
\end{pmatrix}
\]

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

---

Eigenvalues and eigenvectors of a real unsymmetric matrix

— nagf.ht —
Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F02AGF calculates all the eigenvalues and eigenvectors of a real unsymmetric matrix.

2. Specification

```fortran
SUBROUTINE F02AGF (A, IA, N, RR, RI, VR, IVR, VI, IVI, INTGER, IFAIL)
    INTEGER IA, N, IVR, IVI, INTGER(N), IFAIL
    DOUBLE PRECISION A(IA,N), RR(N), RI(N), VR(IVR,N), VI
    (IVI,N)
```

3. Description

The matrix A is first balanced and then reduced to upper Hessenberg form using real stabilised elementary similarity transformations. The eigenvalues and eigenvectors of the Hessenberg matrix are calculated using the QR algorithm. The eigenvectors of the Hessenberg matrix are back-transformed to give the eigenvectors of the original matrix A.

4. References

5. Parameters

1: A(IA,N) -- DOUBLE PRECISION array Input/Output
   On entry: the n by n matrix A. On exit: the array is overwritten.

2: IA -- INTEGER Input
   On entry: the first dimension of the array A as declared in the (sub)program from which F02AGF is called.
   Constraint: IA >= N.

3: N -- INTEGER Input
   On entry: n, the order of the matrix A.

4: RR(N) -- DOUBLE PRECISION array Output
   On exit: the real parts of the eigenvalues.
5: RI(N) -- DOUBLE PRECISION array
   Output
   On exit: the imaginary parts of the eigenvalues.

6: VR(IVR,N) -- DOUBLE PRECISION array
   Output
   On exit: the real parts of the eigenvectors, stored by
   columns. The ith column corresponds to the ith eigenvalue.
   The eigenvectors are normalised so that the sum of the
   squares of the moduli of the elements is equal to 1 and the
   element of largest modulus is real. This ensures that real
   eigenvalues have real eigenvectors.

7: IVR -- INTEGER
   Input
   On entry:
   the first dimension of the array VR as declared in the
   (sub)program from which F02AGF is called.
   Constraint: IVR >= N.

8: VI(IVI,N) -- DOUBLE PRECISION array
   Output
   On exit: the imaginary parts of the eigenvectors, stored by
   columns. The ith column corresponds to the ith eigenvalue.

9: IVI -- INTEGER
   Input
   On entry:
   the first dimension of the array VI as declared in the
   (sub)program from which F02AGF is called.
   Constraint: IVI >= N.

10: INTGER(N) -- INTEGER array
    Output
    On exit: INTGER(i) contains the number of iterations used
    to find the ith eigenvalue. If INTGER(i) is negative, the i
    th eigenvalue is the second of a pair found simultaneously.

    Note that the eigenvalues are found in reverse order,
    starting with the nth.

11: IFAIL -- INTEGER
    Input/Output
    On entry: IFAIL must be set to 0, -1 or 1. For users not
    familiar with this parameter (described in the Essential
    Introduction) the recommended value is 0.

    On exit: IFAIL = 0 unless the routine detects an error (see
    Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
    More than 30*N iterations are required to isolate all the
    eigenvalues.
7. Accuracy

The accuracy of the results depends on the original matrix and the multiplicity of the roots. For a detailed error analysis see Wilkinson and Reinsch [1] pp 352 and 390.

8. Further Comments

The time taken by the routine is approximately proportional to n

9. Example

To calculate all the eigenvalues and eigenvectors of the real matrix:

\[
\begin{pmatrix}
1.5 & 0.1 & 4.5 & -1.5 \\
-22.5 & 3.5 & 12.5 & -2.5 \\
-2.5 & 0.3 & 4.5 & -2.5 \\
-2.5 & 0.1 & 4.5 & 2.5 \\
\end{pmatrix}
\]

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

Calculates all the eigenvalues of a complex matrix
F02AJF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F02AJF calculates all the eigenvalues of a complex matrix.

2. Specification

   SUBROUTINE F02AJF (AR, IAR, AI, IAI, N, RR, RI, INTGER, IFAIL)
   INTEGER IAR, IAI, N, INTGER(N), IFAIL
   DOUBLE PRECISION AR(IAR,N), AI(IAI,N), RR(N), RI(N)

3. Description

The complex matrix A is first balanced and then reduced to upper Hessenberg form using stabilised elementary similarity transformations. The eigenvalues are then found using the modified LR algorithm for complex Hessenberg matrices.

4. References

5. Parameters

1: AR(IAR,N) -- DOUBLE PRECISION array Input/Output
   On entry: the real parts of the elements of the n by n complex matrix A. On exit: the array is overwritten.

2: IAR -- INTEGER Input
   On entry: the first dimension of the array AR as declared in the (sub)program from which F02AJF is called.
   Constraint: IAR >= N.

3: AI(IAI,N) -- DOUBLE PRECISION array Input/Output
   On entry: the imaginary parts of the elements of the n by n complex matrix A. On exit: the array is overwritten.

4: IAI -- INTEGER Input
   On entry: the first dimension of the array AI as declared in the (sub)program from which F02AJF is called.
Constraint: IAI >= N.

5: N -- INTEGER
   On entry: n, the order of the matrix A.

6: RR(N) -- DOUBLE PRECISION array
   On exit: the real parts of the eigenvalues.

7: RI(N) -- DOUBLE PRECISION array
   On exit: the imaginary parts of the eigenvalues.

8: INTEGER(N) -- INTEGER array
   Workspace

9: IFAIL -- INTEGER
   On entry: IFAIL must be set to 0, -1 or 1. For users not
   familiar with this parameter (described in the Essential
   Introduction) the recommended value is 0.
   On exit: IFAIL = 0 unless the routine detects an error (see
   Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL = 1
   More than 30*N iterations are required to isolate all the
   eigenvalues.

7. Accuracy

The accuracy of the results depends on the original matrix and
the multiplicity of the roots. For a detailed error analysis see

8. Further Comments

The time taken by the routine is approximately proportional to n

9. Example

To calculate all the eigenvalues of the complex matrix:

\[\begin{pmatrix}
-21.0+5.0i & 24.60i & 13.6+10.2i & 4.0i \\
22.5i & 26.00-5.00i & 7.5-10.0i & 2.5 \\
-2.0+1.5i & 1.68+2.24i & 4.5-5.0i & 1.5+2.0i \\
-2.5i & -2.60 & -2.7+3.6i & 2.5-5.0i
\end{pmatrix}\]

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation Library software and should be available on-line.

---

Eigenvalues and eigenvectors of a complex matrix

--- nagf.ht ---

F02AKF calculates all the eigenvalues and eigenvectors of a complex matrix.

1. Purpose

F02AKF calculates all the eigenvalues and eigenvectors of a complex matrix.

2. Specification

```fortran
SUBROUTINE F02AKF (AR, IAR, AI, IAI, N, RR, RI, VR, IVR, 1 VI, IVI, INTEGER, IFAIL)
INTEGER IAR, IAI, N, IVR, IVI, INTEGER(N), IFAIL
DOUBLE PRECISION AR(IAR,N), AI(IAI,N), RR(N), RI(N), VR(IVR,N), VI(IVI,N)
```

3. Description

The complex matrix A is first balanced and then reduced to upper
Hessenberg form by stabilised elementary similarity transformations. The eigenvalues and eigenvectors of the Hessenberg matrix are calculated using the LR algorithm. The eigenvectors of the Hessenberg matrix are back-transformed to give the eigenvectors of the original matrix.

4. References

5. Parameters

1: \texttt{AR(IAR,N)} -- DOUBLE PRECISION array Input/Output
On entry: the real parts of the elements of the n by n complex matrix A. On exit: the array is overwritten.

2: \texttt{IAR} -- INTEGER Input
On entry:
the first dimension of the array \texttt{AR} as declared in the (sub)program from which \texttt{F02AKF} is called.
Constraint: \texttt{IAR} \geq N.

3: \texttt{AI(IAI,N)} -- DOUBLE PRECISION array Input/Output
On entry: the imaginary parts of the elements of the n by n complex matrix A. On exit: the array is overwritten.

4: \texttt{IAI} -- INTEGER Input
On entry:
the first dimension of the array \texttt{AI} as declared in the (sub)program from which \texttt{F02AKF} is called.
Constraint: \texttt{IAI} \geq N.

5: \texttt{N} -- INTEGER Input
On entry: n, the order of the matrix A.

6: \texttt{RR(N)} -- DOUBLE PRECISION array Output
On exit: the real parts of the eigenvalues.

7: \texttt{RI(N)} -- DOUBLE PRECISION array Output
On exit: the imaginary parts of the eigenvalues.

8: \texttt{VR(IVR,N)} -- DOUBLE PRECISION array Output
On exit: the real parts of the eigenvectors, stored by columns. The ith column corresponds to the ith eigenvalue. The eigenvectors are normalised so that the sum of squares of the moduli of the elements is equal to 1 and the element of largest modulus is real.

9: \texttt{IVR} -- INTEGER Input
On entry:
the first dimension of the array VR as declared in the
(sub)program from which F02AKF is called.
Constraint: IVR >= N.

10: VI(IVI,N) -- DOUBLE PRECISION array Output
On exit: the imaginary parts of the eigenvectors, stored by
columns. The ith column corresponds to the ith eigenvalue.

11: IVI -- INTEGER Input
On entry:
the first dimension of the array VI as declared in the
(sub)program from which F02AKF is called.
Constraint: IVI >= N.

12: INTEGER(N) -- INTEGER array Workspace

13: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not
familiar with this parameter (described in the Essential
Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see
Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
More than 30*N iterations are required to isolate all the
eigenvalues.

7. Accuracy

The accuracy of the results depends on the conditioning of the
original matrix and the multiplicity of the roots. For a detailed

8. Further Comments

The time taken by the routine is approximately proportional to n

9. Example

To calculate all the eigenvalues and eigenvectors of the complex
matrix:

\((-21.0-5.0i \quad 24.60i \quad 13.6+10.2i \quad 4.0i)\)
The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available online.

Eigenvalues of a complex Hermitian matrix

— nagf.h —

---

F02AWF(3NAG) Foundation Library (12/10/92) F02AWF(3NAG)

F02 -- Eigenvalue and Eigenvectors
F02AWF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F02AWF calculates all the eigenvalues of a complex Hermitian matrix.

2. Specification

```
SUBROUTINE F02AWF (AR, IAR, AI, IAI, N, R, WK1, WK2, WK3, 1
  IFAIL)
  INTEGER IAR, IAI, N, IFAIL
  DOUBLE PRECISION AR(IAR,N), AI(IAI,N), R(N), WK1(N),
```
3. Description

The complex Hermitian matrix $A$ is first reduced to a real tridiagonal matrix by $n-2$ unitary transformations, and a subsequent diagonal transformation. The eigenvalues are then derived using the QL algorithm, an adaptation of the QR algorithm.

4. References

5. Parameters

1: $\text{AR}(\text{IAR},N)$ -- DOUBLE PRECISION array Input/Output
   On entry: the real parts of the elements of the lower triangle of the $n$ by $n$ complex Hermitian matrix $A$. Elements of the array above the diagonal need not be set. On exit: the array is overwritten.

2: $\text{IAR}$ -- INTEGER Input
   On entry: the first dimension of the array $\text{AR}$ as declared in the (sub)program from which F02AWF is called.
   Constraint: $\text{IAR} \geq N$.

3: $\text{AI}(\text{IAI},N)$ -- DOUBLE PRECISION array Input/Output
   On entry: the imaginary parts of the elements of the lower triangle of the $n$ by $n$ complex Hermitian matrix $A$. Elements of the array above the diagonal need not be set. On exit: the array is overwritten.

4: $\text{IAI}$ -- INTEGER Input
   On entry: the first dimension of the array $\text{AI}$ as declared in the (sub)program from which F02AWF is called.
   Constraint: $\text{IAI} \geq N$.

5: $N$ -- INTEGER Input
   On entry: $n$, the order of the complex Hermitian matrix, $A$.

6: $\text{R}(N)$ -- DOUBLE PRECISION array Output
   On exit: the eigenvalues in ascending order.
7: WK1(N) -- DOUBLE PRECISION array Workspace
8: WK2(N) -- DOUBLE PRECISION array Workspace
9: WK3(N) -- DOUBLE PRECISION array Workspace
10: IFAIL -- INTEGER Input/Output
    On entry: IFAIL must be set to 0, -1 or 1. For users not
    familiar with this parameter (described in the Essential
    Introduction) the recommended value is 0.
    On exit: IFAIL = 0 unless the routine detects an error (see
    Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
    More than 30*N iterations are required to isolate all the
    eigenvalues.

7. Accuracy

For a detailed error analysis see Peters [1] page 3 and Wilkinson

8. Further Comments

The time taken by the routine is approximately proportional to n

9. Example

To calculate all the eigenvalues of the complex Hermitian matrix:

\begin{verbatim}
(0.50  0.00  1.84+1.38i  2.08-1.56i)
(0.00  0.50  1.12+0.84i -0.56+0.42i)
(1.84-1.38i 1.12-0.84i  0.50  0.00 )
(2.08+1.56i -0.56-0.42i  0.00  0.50 )
\end{verbatim}

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.
Eigenvalues/eigenvectors complex Hermitian matrix

---

\begin{verbatim}
F02AXF(3NAG) Foundation Library (12/10/92) F02AXF(3NAG)
\end{verbatim}

1. Purpose

F02AXF calculates all the eigenvalues and eigenvectors of a complex Hermitian matrix.

2. Specification

\begin{verbatim}
SUBROUTINE F02AXF (AR, IAR, AI, IAI, N, R, VR, IVR, VI, 
1 IVI, WK1, WK2, WK3, IFAIL)
INTEGER IAR, IAI, N, IVR, IVI, IFAIL
DOUBLE PRECISION AR(IAR,N), AI(IAI,N), R(N), VR(IVR,N), VI 
1 (IVI,N), WK1(N), WK2(N), WK3(N)
\end{verbatim}

3. Description

The complex Hermitian matrix is first reduced to a real tridiagonal matrix by n-2 unitary transformations and a subsequent diagonal transformation. The eigenvalues and eigenvectors are then derived using the QL algorithm, an adaptation of the QR algorithm.

4. References

5. Parameters

1: AR(IAR,N) -- DOUBLE PRECISION array
   Input
   On entry: the real parts of the elements of the lower
   triangle of the n by n complex Hermitian matrix A. Elements
   of the array above the diagonal need not be set. See also
   Section 8.

2: IAR -- INTEGER
   Input
   On entry:
   the first dimension of the array AR as declared in the
   (sub)program from which F02AXF is called.
   Constraint: IAR >= N.

3: AI(IAI,N) -- DOUBLE PRECISION array
   Input
   On entry: the imaginary parts of the elements of the lower
   triangle of the n by n complex Hermitian matrix A. Elements
   of the array above the diagonal need not be set. See also
   Section 8.

4: IAI -- INTEGER
   Input
   On entry:
   the first dimension of the array AI as declared in the
   (sub)program from which F02AXF is called.
   Constraint: IAI >= N.

5: N -- INTEGER
   Input
   On entry: n, the order of the matrix, A.

6: R(N) -- DOUBLE PRECISION array
   Output
   On exit: the eigenvalues in ascending order.

7: VR(IVR,N) -- DOUBLE PRECISION array
   Output
   On exit: the real parts of the eigenvectors, stored by
   columns. The ith column corresponds to the ith eigenvector.
   The eigenvectors are normalised so that the sum of the
   squares of the moduli of the elements is equal to 1 and the
   element of largest modulus is real. See also Section 8.

8: IVR -- INTEGER
   Input
   On entry:
   the first dimension of the array VR as declared in the
   (sub)program from which F02AXF is called.
   Constraint: IVR >= N.
9: VI(IVI,N) -- DOUBLE PRECISION array 
On exit: the imaginary parts of the eigenvectors, stored by 
columns. The ith column corresponds to the ith eigenvector. 
See also Section 8.

10: IVI -- INTEGER 
On entry: 
the first dimension of the array VI as declared in the 
(sub)program from which F02AXF is called. 
Constraint: IVI >= N.

11: WK1(N) -- DOUBLE PRECISION array 
12: WK2(N) -- DOUBLE PRECISION array 
13: WK3(N) -- DOUBLE PRECISION array 
Workspace

14: IFAIL -- INTEGER 
On entry: IFAIL must be set to 0, -1 or 1. For users not 
familiar with this parameter (described in the Essential 
Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see 
Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1 
More than 30*N iterations are required to isolate all the 
eigenvalues.

IFAIL= 2 
The diagonal elements of AI are not all zero, i.e., the 
complex matrix is not Hermitian.

7. Accuracy

The eigenvectors are always accurately orthogonal but the 
accuracy of the individual eigenvalues and eigenvectors is 
dependent on their inherent sensitivity to small changes in the 
original matrix. For a detailed error analysis see Peters [1] 

8. Further Comments

The time taken by the routine is approximately proportional to n
Unless otherwise stated in the implementation document, the routine may be called with the same actual array supplied for parameters AR and VR, and for AI and VI, in which case the eigenvectors will overwrite the original matrix A. However this is not standard Fortran 77, and may not work on all systems.

9. Example

To calculate the eigenvalues and eigenvectors of the complex Hermitian matrix:

\[
\begin{pmatrix}
0.50 & 0.00 & 1.84+1.38i & 2.08-1.56i \\
0.00 & 0.50 & 1.12+0.84i & -0.56+0.42i \\
1.84-1.38i & 1.12-0.84i & 0.50 & 0.00 \\
2.08+1.56i & -0.56-0.42i & 0.00 & 0.50
\end{pmatrix}
\]

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

Eigenvalues and eigenvectors of a real symmetric matrix

— nagf.ht —

Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.
1. Purpose

F02BBF calculates selected eigenvalues and eigenvectors of a real symmetric matrix by reduction to tridiagonal form, bisection and inverse iteration, where the selected eigenvalues lie within a given interval.

2. Specification

SUBROUTINE F02BBF (A, IA, N, ALB, UB, M, MM, R, V, IV, D, 1 E, E2, X, G, C, ICOUNT, IFAIL)
INTEGER IA, N, M, MM, IV, IFAIL
DOUBLE PRECISION A(IA,N), ALB, UB, R(M), V(IV,M), D(N), E 1 (N), E2(N), X(N,7), G(N)
LOGICAL C(N)

3. Description

The real symmetric matrix A is reduced to a symmetric tridiagonal matrix T by Householder’s method. The eigenvalues which lie within a given interval [l,u], are calculated by the method of bisection. The corresponding eigenvectors of T are calculated by inverse iteration. A back-transformation is then performed to obtain the eigenvectors of the original matrix A.

4. References

5. Parameters

1: A(IA,N) -- DOUBLE PRECISION array Input/Output
On entry: the lower triangle of the n by n symmetric matrix A. The elements of the array above the diagonal need not be set. On exit: the elements of A below the diagonal are overwritten, and the rest of the array is unchanged.

2: IA -- INTEGER Input
On entry:
the first dimension of the array A as declared in the (sub)program from which F02BBF is called.
Constraint: IA >= N.

3: N -- INTEGER Input
On entry: n, the order of the matrix A.

4: ALB -- DOUBLE PRECISION Input
5: UB -- DOUBLE PRECISION
   Input
   On entry: l and u, the lower and upper end-points of the
   interval within which eigenvalues are to be calculated.

6: M -- INTEGER
   Input
   On entry: an upper bound for the number of eigenvalues
   within the interval.

7: MM -- INTEGER
   Output
   On exit: the actual number of eigenvalues within the
   interval.

8: R(M) -- DOUBLE PRECISION array
   Output
   On exit: the eigenvalues, not necessarily in ascending
   order.

9: V(IV,M) -- DOUBLE PRECISION array
   Output
   On exit: the eigenvectors, stored by columns. The ith
   column corresponds to the ith eigenvalue. The eigenvectors
   are normalised so that the sum of the squares of the
   elements are equal to 1.

10: IV -- INTEGER
    Input
    On entry:
    the first dimension of the array V as declared in the
    (sub)program from which F02BBF is called.
    Constraint: IV >= N.

11: D(N) -- DOUBLE PRECISION array
    Workspace
    E(N) -- DOUBLE PRECISION array
    Workspace
    E2(N) -- DOUBLE PRECISION array
    Workspace
    X(N,7) -- DOUBLE PRECISION array
    Workspace
    G(N) -- DOUBLE PRECISION array
    Workspace
    C(N) -- LOGICAL array
    Workspace

12: ICOUNT(M) -- INTEGER array
    Output
    On exit: ICOUNT(i) contains the number of iterations for
    the ith eigenvalue.

13: IFAIL -- INTEGER
    Input/Output
    On entry: IFAIL must be set to 0, -1 or 1. For users not
    familiar with this parameter (described in the Essential
    Introduction) the recommended value is 0.
    On exit: IFAIL = 0 unless the routine detects an error (see
Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL = 1
  M is less than the number of eigenvalues in the given interval. On exit M contains the number of eigenvalues in the interval. Rerun with this value for M.

IFAIL = 2
  More than 5 iterations are required to determine any one eigenvector.

7. Accuracy

There is no guarantee of the accuracy of the eigenvectors as the results depend on the original matrix and the multiplicity of the roots. For a detailed error analysis see Wilkinson and Reinsch [1] pp 222 and 436.

8. Further Comments

The time taken by the routine is approximately proportional to n^3

This subroutine should only be used when less than 25% of the eigenvalues and the corresponding eigenvectors are required. Also this subroutine is less efficient with matrices which have multiple eigenvalues.

9. Example

To calculate the eigenvalues lying between -2.0 and 3.0, and the corresponding eigenvectors of the real symmetric matrix:

\[
\begin{pmatrix}
0.5 & 0.0 & 2.3 & -2.6 \\
0.0 & 0.5 & -1.4 & -0.7 \\
2.3 & -1.4 & 0.5 & 0.0 \\
-2.6 & -0.7 & 0.0 & 0.5
\end{pmatrix}
\]

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
Eigenvalues of generalized eigenproblem $Ax = \lambda Bx$

— nagf.ht —

```
F02BJF(3NAG) Foundation Library (12/10/92) F02BJF(3NAG)

F02 -- Eigenvalue and Eigenvectors
F02BJF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for
your implementation to check implementation-dependent details.
The symbol (*) after a NAG routine name denotes a routine that is
not included in the Foundation Library.

1. Purpose

F02BJF calculates all the eigenvalues and, if required, all the
eigenvectors of the generalized eigenproblem $Ax = \lambda Bx$
where $A$ and $B$ are real, square matrices, using the QZ algorithm.

2. Specification

```fortran
SUBROUTINE F02BJF (N, A, IA, B, IB, EPS1, ALFR, ALFI,
                   1      BETA, MATV, V, IV, ITER, IFAIL)
INTEGER N, IA, IB, IV, ITER(N), IFAIL
DOUBLE PRECISION A(IA,N), B(IB,N), EPS1, ALFR(N), ALFI(N),
                   1      BETA(N), V(IV,N)
LOGICAL MATV
```

3. Description

All the eigenvalues and, if required, all the eigenvectors of the
generalized eigenproblem $Ax = \lambda Bx$ where $A$ and $B$ are real,
Square matrices, are determined using the QZ algorithm. The QZ
algorithm consists of 4 stages:

(a) $A$ is reduced to upper Hessenberg form and at the same time
$B$ is reduced to upper triangular form.
(b) A is further reduced to quasi-triangular form while the triangular form of B is maintained.

(c) The quasi-triangular form of A is reduced to triangular form and the eigenvalues extracted. This routine does not actually produce the eigenvalues \((\text{lambda})\) , but instead returns \((\alpha)\) and \((\beta)\) such that

\[
\text{lambda}_j = \frac{\alpha_j}{\beta_j}, \quad j=1,2,...,n
\]

The division by \((\beta)\) becomes the responsibility of the user's program, since \((\beta)\) may be zero indicating an infinite eigenvalue. Pairs of complex eigenvalues occur with \((\alpha) / (\beta)\) and \((\alpha) / (\beta)\) complex conjugates, even though \((\alpha)\) and \((\alpha)\) are not conjugate.

(d) If the eigenvectors are required (MATV = .TRUE.), they are obtained from the triangular matrices and then transformed back into the original co-ordinate system.

4. References

5. Parameters

1: \(N\) -- INTEGER Input
   On entry: \(n\), the order of the matrices A and B.

2: \(A(IA,N)\) -- DOUBLE PRECISION array Input/Output
   On entry: the \(n\) by \(n\) matrix A. On exit: the array is overwritten.
3: IA -- INTEGER
   On entry:
   the first dimension of the array A as declared in the
   (sub)program from which F02BJF is called.
   Constraint: IA >= N.

4: B(IB,N) -- DOUBLE PRECISION array
   On entry: the n by n matrix B. On exit: the array is
   overwritten.

5: IB -- INTEGER
   On entry:
   the first dimension of the array B as declared in the
   (sub)program from which F02BJF is called.
   Constraint: IB >= N.

6: EPS1 -- DOUBLE PRECISION
   On entry: the tolerance used to determine negligible
   elements. If EPS1 > 0.0, an element will be considered
   negligible if it is less than EPS1 times the norm of its
   matrix. If EPS1 <= 0.0, machine precision is used in place
   of EPS1. A positive value of EPS1 may result in faster
   execution but less accurate results.

7: ALFR(N) -- DOUBLE PRECISION array
8: ALFI(N) -- DOUBLE PRECISION array
   On exit: the real and imaginary parts of (alpha), for
   j=1,2,...,n.

9: BETA(N) -- DOUBLE PRECISION array
   On exit: (beta), for j=1,2,...,n.

10: MATV -- LOGICAL
    On entry: MATV must be set .TRUE. if the eigenvectors are
    required, otherwise .FALSE..

11: V(IV,N) -- DOUBLE PRECISION array
    On exit: if MATV = .TRUE., then
    (i) if the jth eigenvalue is real, the jth column of V
    contains its eigenvector;
    (ii) if the jth and (j+1)th eigenvalues form a complex
    pair, the jth and (j+1)th columns of V contain the
    real and imaginary parts of the eigenvector associated
    with the first eigenvalue of the pair. The conjugate
    of this vector is the eigenvector for the conjugate
    eigenvalue.
Each eigenvector is normalised so that the component of largest modulus is real and the sum of squares of the moduli equal one.

If MATV = .FALSE., V is not used.

12: IV -- INTEGER Input
On entry: the first dimension of the array V as declared in the (sub)program from which F02BJF is called.
Constraint: IV >= N.

13: ITER(N) -- INTEGER array Output
On exit: ITER(j) contains the number of iterations needed to obtain the jth eigenvalue. Note that the eigenvalues are obtained in reverse order, starting with the nth.

14: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= i
More than 30*N iterations are required to determine all the diagonal i by 1 or 2 by 2 blocks of the quasi-triangular form in the second step of the QZ algorithm. IFAIL is set to the index i of the eigenvalue at which this failure occurs. If the soft failure option is used, (alpha) and (beta) are correct for j=i+1,i+2,...,n, but V does not contain any correct eigenvectors.

7. Accuracy

The computed eigenvalues are always exact for a problem (A+E)x=(lambda)(B+F)x where ||E||/||A|| and ||F||/||B|| are both of the order of max(EPS1,(epsilon)), EPS1 being defined as in Section 5 and (epsilon) being the machine precision.

Note: interpretation of results obtained with the QZ algorithm often requires a clear understanding of the effects of small changes in the original data. These effects are reviewed in Wilkinson [3], in relation to the significance of small values of
(alpha) and (beta). It should be noted that if (alpha) and 
\[ j \quad j \quad j \]
(beta) are both small for any j, it may be that no reliance can 
\[ j \]
be placed on any of the computed eigenvalues 
\[ \lambda = \frac{\text{alpha}}{\text{beta}} \]. The user is recommended to study [3] 
i \quad i \quad i 
and, if in difficulty, to seek expert advice on determining the 
sensitivity of the eigenvalues to perturbations in the data.

8. Further Comments

The time taken by the routine is approximately proportional to \( n \) and also depends on the value chosen for parameter EPS1.

9. Example

To find all the eigenvalues and eigenvectors of \( Ax = \lambda Bx \) where

\[
\begin{pmatrix}
3.9 & 12.5 & -34.5 & -0.5 \\
4.3 & 21.5 & -47.5 & 7.5 \\
\end{pmatrix}
\]

\[
A = \begin{pmatrix}
4.3 & 21.5 & -43.5 & 3.5 \\
4.4 & 26.0 & -46.0 & 6.0 \\
\end{pmatrix}
\]

and

\[
\begin{pmatrix}
1 & 2 & -3 & 1 \\
1 & 3 & -5 & 4 \\
\end{pmatrix}
\]

\[
B = \begin{pmatrix}
1 & 3 & -4 & 3 \\
1 & 3 & -4 & 4 \\
\end{pmatrix}
\]

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
F02FJF(3NAG) Foundation Library (12/10/92) F02FJF(3NAG)

F02 -- Eigenvalue and Eigenvectors
F02FJF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose
To find eigenvalues and eigenvectors of a real sparse symmetric or generalized symmetric eigenvalue problem.

2. Specification

```
SUBROUTINE F02FJF (N, M, K, NOITS, TOL, DOT, IMAGE, MONIT,
                   NOVECS, X, NRX, D, WORK, LWORK, RWORK,
                   LRWORK, IWORK, LIWORK, IFAIL)
```

```
INTEGER N, M, K, NOITS, NOVECS, NRX, LWORK, LIWORK, IFAIL
DOUBLE PRECISION TOL, DOT, X(NRX,K), D(K), WORK(LWORK),
                   RWORK(LRWORK)
EXTERNAL DOT, IMAGE, MONIT
```

3. Description

F02FJF finds the m eigenvalues of largest absolute value and the corresponding eigenvectors for the real eigenvalue problem

\[ Cx = \lambda x \]  \hspace{1cm} (1) \]

where \( C \) is an \( n \) by \( n \) matrix such that

\[ T \]

\[ BC = C B \]  \hspace{1cm} (2) \]

for a given positive-definite matrix \( B \). \( C \) is said to be \( B \)-symmetric. Different specifications of \( C \) allow for the solution of a variety of eigenvalue problems. For example, when
the routine finds the $m$ eigenvalues of largest absolute magnitude for the standard symmetric eigenvalue problem

$$Ax = (\lambda)x.$$  \hfill (3)

The routine is intended for the case where $A$ is sparse.

As a second example, when

$$C = B^{-1}A$$

where

$$A = A^T$$

the routine finds the $m$ eigenvalues of largest absolute magnitude for the generalized symmetric eigenvalue problem

$$Ax = (\lambda)Bx.$$  \hfill (4)

The routine is intended for the case where $A$ and $B$ are sparse.

The routine does not require $C$ explicitly, but $C$ is specified via a user-supplied routine $\text{IMAGE}$ which, given an $n$ element vector $z$, computes the image $w$ given by

$$w = Cz.$$  

For instance, in the above example, where $C = B^{-1}A$, routine $\text{IMAGE}$ will need to solve the positive-definite system of equations $Bw = Az$ for $w$.

To find the $m$ eigenvalues of smallest absolute magnitude of (3)

$$w = C^{-1}z.$$  

we can choose $C = A^{-1}$ and hence find the reciprocals of the required eigenvalues, so that $\text{IMAGE}$ will need to solve $Aw = z$ for $w$, and correspondingly for (4) we can choose $C = A^{-1}B$ and solve $Aw = Bz$ for $w$.

A table of examples of choice of $\text{IMAGE}$ is given in Table 3.1. It should be remembered that the routine also returns the corresponding eigenvectors and that $B$ is positive-definite. Throughout $A$ is assumed to be symmetric and, where necessary,
non-singularity is also assumed.

<td>$Ax = \lambda x$</td>
<td>$(B=I)Ax = \lambda Bx$</td>
</tr>
<tr>
<td>$ABx = \lambda x$</td>
<td></td>
</tr>
</tbody>
</table>

Largest:
- Compute $w = Az$
- Solve $Bw = Az$
- Compute $w = ABz$

Smallest ($\nu = 1/(\lambda)$):
- Solve $Aw = Az$
- Solve $Av = Bz$
- Solve $Aw = z, Bw = (\nu)$

Furthest from $w = (A-(\sigma)I)z$:
- Compute $w = (A-(\sigma)B)z$
- Compute $w = (AB-(\sigma)I)z$

Closest to $(\sigma)$ ($\nu = 1/(\lambda-(\sigma))$):
- Solve $(A-(\sigma)I)w = z$
- Solve $(A-(\sigma)B)w = Bz$
- Solve $(AB-(\sigma)I)w = z$

Table 3.1
The Requirement of IMAGE for Various Problems

The matrix $B$ also need not be supplied explicitly, but is specified via a user-supplied routine DOT which, given $n$ element $T$ vectors $z$ and $w$, computes the generalized dot product $wBz$.

F02FJF is based upon routine SIMITZ (see Nikolai [1]), which is itself a derivative of the Algol procedure ritzit (see Rutishauser [4]), and uses the method of simultaneous (subspace) iteration. (See Parlett [2] for description, analysis and advice on the use of the method.)

The routine performs simultaneous iteration on $k > m$ vectors.
Initial estimates to $p = k$ eigenvectors, corresponding to the $p$ eigenvalues of $C$ of largest absolute value, may be supplied by the user to F02FJF. When possible $k$ should be chosen so that the $k$th eigenvalue is not too close to the $m$ required eigenvalues, but if $k$ is initially chosen too small then F02FJF may be re-entered, supplying approximations to the $k$ eigenvectors found so far and with $k$ then increased.
At each major iteration F02FJF solves an $r \times r$ ($r \leq k$) eigenvalue sub-problem in order to obtain an approximation to the eigenvalues for which convergence has not yet occurred. This approximation is refined by Chebyshev acceleration.

4. References

5. Parameters

1: $N$ -- INTEGER Input
   On entry: $n$, the order of the matrix $C$. Constraint: $N \geq 1$.

2: $M$ -- INTEGER Input/Output
   On entry: $m$, the number of eigenvalues required.
   Constraint: $M \geq 1$. On exit: $m$, the number of eigenvalues actually found. It is equal to $m$ if IFAIL = 0 on exit, and is less than $m$ if IFAIL = 2, 3 or 4. See Section 6 and Section 8 for further information.

3: $K$ -- INTEGER Input
   On entry: the number of simultaneous iteration vectors to be used. Too small a value of $K$ may inhibit convergence, while a larger value of $K$ incurs additional storage and additional work per iteration. Suggested value: $K = M + 4$ will often be a reasonable choice in the absence of better information.
   Constraint: $M < K \leq N$.

4: NOITS -- INTEGER Input/Output
   On entry: the maximum number of major iterations (eigenvalue sub-problems) to be performed. If NOITS $\leq 0$, then the value 100 is used in place of NOITS. On exit: the number of iterations actually performed.

5: TOL -- DOUBLE PRECISION Input
   On entry: a relative tolerance to be used in accepting
eigenvalues and eigenvectors. If the eigenvalues are required to about \( t \) significant figures, then \( TOL \) should be set to about \( 10^{-t} \). \( d \) is accepted as an eigenvalue as soon as two successive approximations to \( d \) differ by less than \( (|d| \times TOL)/10 \), where \( d \) is the latest approximation to \( d \).

Once an eigenvalue has been accepted, then an eigenvector is accepted as soon as \( (d_f)/(d-d_k) < TOL \), where \( f \) is the normalised residual of the current approximation to the eigenvector (see Section 8 for further information). The values of the \( f \) and \( d \) can be printed from routine MONIT.

If \( TOL \) is supplied outside the range \((\epsilon), 1.0\), where \( \epsilon \) is the machine precision, then the value \( \epsilon \) is used in place of \( TOL \).

6: **DOT** -- DOUBLE PRECISION FUNCTION, supplied by the user.

External Procedure

\[
T = \text{DOT}(\text{IFLAG}, N, z, w, RWORK, \text{LRWORK}, IWORK, \text{LIWORK})
\]

**DOUBLE PRECISION FUNCTION DOT** (IFLAG, N, Z, W, RWORK, LRWORK, IWORK, LIWORK)

1: **IFLAG** -- INTEGER

On entry: IFLAG is always non-negative. On exit: IFLAG may be used as a flag to indicate a failure in the computation of \( w Bz \). If IFLAG is negative on exit from DOT, then F02FJF will exit immediately with IFAIL set to IFLAG. Note that in this case DOT must still be assigned a value.

2: **N** -- INTEGER

On entry: the number of elements in the vectors \( z \) and \( w \) and the order of the matrix \( B \).
3: \( Z(N) \) -- DOUBLE PRECISION array \( T \) 
On entry: the vector \( z \) for which \( w \) \( Bz \) is required.

4: \( W(N) \) -- DOUBLE PRECISION array \( T \) 
On entry: the vector \( w \) for which \( w \) \( Bz \) is required.

5: \( RWORK(LRWORK) \) -- DOUBLE PRECISION array \( \) User Workspace

6: \( LRWORK \) -- INTEGER \( \) Input

7: \( IWORK(LIWORK) \) -- INTEGER array \( \) User Workspace

8: \( LIWORK \) -- INTEGER \( \) Input
DOT is called from F02FJF with the parameters RWORK, LRWORK, IWORK and LIWORK as supplied to F02FJF. The user is free to use the arrays RWORK and IWORK to supply information to DOT and to IMAGE as an alternative to using COMMON.

DOT must be declared as EXTERNAL in the (sub)program from which F02FJF is called. Parameters denoted as Input must not be changed by this procedure.

7: \( IMAGE \) -- SUBROUTINE, supplied by the user. 
External Procedure

IMAGE must return the vector \( w=Cz \) for a given vector \( z \).

Its specification is:

\[
\text{SUBROUTINE IMAGE (IFLAG, N, Z, W, RWORK, LRWORK, IWORK(LIWORK))}
\]

1: \( IFLAG \) -- INTEGER \( \) Input/Output
On entry: IFLAG is always non-negative. On exit: IFLAG may be used as a flag to indicate a failure in the computation of \( w \). If IFLAG is negative on exit from IMAGE, then F02FJF will exit immediately with IFAIL set to IFLAG.

2: \( N \) -- INTEGER \( \) Input
On entry: \( n \), the number of elements in the vectors \( w \) and \( z \), and the order of the matrix \( C \).
3: Z(N) -- DOUBLE PRECISION array
On entry: the vector z for which Cz is required.

4: W(N) -- DOUBLE PRECISION array
On exit: the vector w=Cz.

5: RWORK(LRWORK) -- DOUBLE PRECISION array User Workspace

6: LRWORK -- INTEGER Input

7: IWORK(LIWORK) -- INTEGER array User Workspace

8: LIWORK -- INTEGER Input

IMAGE is called from F02FJF with the parameters RWORK, LRWORK, IWORK and LIWORK as supplied to F02FJF. The user is free to use the arrays RWORK and IWORK to supply information to IMAGE and DOT as an alternative to using COMMON.

IMAGE must be declared as EXTERNAL in the (sub)program from which F02FJF is called. Parameters denoted as Input must not be changed by this procedure.

8: MONIT -- SUBROUTINE, supplied by the user.

MONIT is used to monitor the progress of F02FJF. MONIT may be the dummy subroutine F02JZ if no monitoring is actually required. (F02JZ is included in the NAG Foundation Library and so need not be supplied by the user. The routine name F02JZ may be implementation dependent: see the Users’ Note for your implementation for details.) MONIT is called after the solution of each eigenvalue sub-problem and also just prior to return from F02FJF. The parameters ISTATE and NEXTIT allow selective printing by MONIT.

Its specification is:

SUBROUTINE MONIT (ISTATE, NEXTIT, NEVALS,
 1 NEVECS, K, F, D)
 1 INTEGER       ISTATE, NEXTIT, NEVALS, NEVECS,
 1 K
 1 DOUBLE PRECISION F(K), D(K)

1: ISTATE -- INTEGER Input
On entry: ISTATE specifies the state of F02FJF and will have values as follows:
ISTATE = 0
No eigenvalue or eigenvector has just been accepted.
ISTATE = 1
One or more eigenvalues have been accepted since
the last call to MONIT.

ISTATE = 2
One or more eigenvectors have been accepted since
the last call to MONIT.

ISTATE = 3
One or more eigenvalues and eigenvectors have
been accepted since the last call to MONIT.

ISTATE = 4
Return from F02FJF is about to occur.

2: NEXTIT -- INTEGER Input
On entry: the number of the next iteration.

3: NEVALS -- INTEGER Input
On entry: the number of eigenvalues accepted so far.

4: NEVECS -- INTEGER Input
On entry: the number of eigenvectors accepted so far.

5: K -- INTEGER Input
On entry: k, the number of simultaneous iteration
vectors.

6: F(K) -- DOUBLE PRECISION array Input
On entry: a vector of error quantities measuring the
state of convergence of the simultaneous iteration
vectors. See the parameter TOL of F02FJF above and
Section 8 for further details. Each element of F is
initially set to the value 4.0 and an element remains
at 4.0 until the corresponding vector is tested.

7: D(K) -- DOUBLE PRECISION array Input
On entry: D(i) contains the latest approximation to the
absolute value of the ith eigenvalue of C.
MONIT must be declared as EXTERNAL in the (sub)program
from which F02FJF is called. Parameters denoted as
Input must not be changed by this procedure.

9: NOVECS -- INTEGER Input
On entry: the number of approximate vectors that are being
supplied in X. If NOVECS is outside the range (0,K), then
the value 0 is used in place of NOVECS.

10: X(NRX,K) -- DOUBLE PRECISION array Input/Output
On entry: if 0 < NOVECS <= K, the first NOVECS columns of X
must contain approximations to the eigenvectors corresponding to the NOVECS eigenvalues of largest absolute value of C. Supplying approximate eigenvectors can be useful when reasonable approximations are known, or when the routine is being restarted with a larger value of K. Otherwise it is not necessary to supply approximate vectors, as simultaneous iteration vectors will be generated randomly by the routine. On exit: if IFAIL = 0, 2, 3 or 4, the first \( m' \) columns contain the eigenvectors corresponding to the eigenvalues returned in the first \( m' \) elements of D (see below); and the next \( k-m'-1 \) columns contain approximations to the eigenvectors corresponding to the approximate eigenvalues returned in the next \( k-m'-1 \) elements of D. Here \( m' \) is the value returned in M (see above), the number of eigenvalues actually found. The kth column is used as workspace.

11: \( NRX -- INTEGER \) Input
On entry: the first dimension of the array X as declared in the (sub)program from which F02FJF is called.
Constraint: \( NRX >= N \).

12: \( D(K) -- DOUBLE PRECISION array \) Output
On exit: if IFAIL = 0, 2, 3 or 4, the first \( m' \) elements contain the first \( m' \) eigenvalues in decreasing order of magnitude; and the next \( k-m'-1 \) elements contain approximations to the next \( k-m'-1 \) eigenvalues. Here \( m' \) is the value returned in M (see above), the number of eigenvalues actually found. \( D(k) \) contains the value \( e \) where \( (-e,e) \) is the latest interval over which Chebyshev acceleration is performed.

13: \( WORK(LWORK) -- DOUBLE PRECISION array \) Workspace

14: \( LWORK -- INTEGER \) Input
On entry: the length of the array WORK, as declared in the (sub)program from which F02FJF is called. Constraint: \( LWORK >= 3*K + \max(K*K,2*N) \).

15: \( RWORK(LRWORK) -- DOUBLE PRECISION array \) User Workspace
RWORK is not used by F02FJF, but is passed directly to routines DUT and IMAGE and may be used to supply information to these routines.

16: \( LRWORK -- INTEGER \) Input
On entry: the length of the array RWORK, as declared in the (sub)program from which F02FJF is called. Constraint: \( LRWORK >= 1 \).
17: IWORK(LIWORK) -- INTEGER array
User Workspace
IWORK is not used by F02FJF, but is passed directly to
routines DOT and IMAGE and may be used to supply information
to these routines.

18: LIWORK -- INTEGER
Input
On entry: the length of the array IWORK, as declared in the
(sub)program from which F02FJF is called. Constraint: LIWORK
\geq 1.

19: IFAIL -- INTEGER
Input/Output
On entry: IFAIL must be set to 0, -1 or 1. Users who are
unfamiliar with this parameter should refer to the Essential
Introduction for details.

On exit: IFAIL = 0 unless the routine detects an error or
gives a warning (see Section 6).

For this routine, because the values of output parameters
may be useful even if IFAIL /=0 on exit, users are
recommended to set IFAIL to -1 before entry. It is then
essential to test the value of IFAIL on exit. To suppress
the output of an error message when soft failure occurs, set
IFAIL to 1.

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

IFAIL< 0
A negative value of IFAIL indicates an exit from F02FJF
because the user has set IFLAG negative in DOT or IMAGE. The
value of IFAIL will be the same as the user’s setting of
IFLAG.

IFAIL= 1
On entry N < 1,
or M < 1,
or M \geq K,
or K > N,
or NRX < N,
or LWORK <3\times K+max(K\times K,N),
or LRWORK < 1,
or \( \text{LIWORK} < 1 \).

**IFAIL= 2**

Not all the requested eigenvalues and vectors have been obtained. Approximations to the \( r \)th eigenvalue are oscillating rapidly indicating that severe cancellation is occurring in the \( r \)th eigenvector and so \( M \) is returned as \((r-1)\). A restart with a larger value of \( K \) may permit convergence.

**IFAIL= 3**

Not all the requested eigenvalues and vectors have been obtained. The rate of convergence of the remaining eigenvectors suggests that more than \( \text{NOITS} \) iterations would be required and so the input value of \( M \) has been reduced. A restart with a larger value of \( K \) may permit convergence.

**IFAIL= 4**

Not all the requested eigenvalues and vectors have been obtained. \( \text{NOITS} \) iterations have been performed. A restart, possibly with a larger value of \( K \), may permit convergence.

**IFAIL= 5**

This error is very unlikely to occur, but indicates that convergence of the eigenvalue sub-problem has not taken place. Restarting with a different set of approximate vectors may allow convergence. If this error occurs the user should check carefully that \( \text{F02FJF} \) is being called correctly.

7. **Accuracy**

Eigenvalues and eigenvectors will normally be computed to the accuracy requested by the parameter \( \text{TOL} \), but eigenvectors corresponding to small or to close eigenvalues may not always be computed to the accuracy requested by the parameter \( \text{TOL} \). Use of the routine \( \text{MONIT} \) to monitor acceptance of eigenvalues and eigenvectors is recommended.

8. **Further Comments**

The time taken by the routine will be principally determined by the time taken to solve the eigenvalue sub-problem and the time taken by the routines \( \text{DOT} \) and \( \text{IMAGE} \). The time taken to solve an eigenvalue sub-problem is approximately proportional to \( nk \). It is important to be aware that several calls to \( \text{DOT} \) and \( \text{IMAGE} \) may occur on each major iteration.
As can be seen from Table 3.1, many applications of F02FJF will require routine IMAGE to solve a system of linear equations. For example, to find the smallest eigenvalues of $Ax = (\lambda)x$, IMAGE needs to solve equations of the form $Aw = Bz$ for $w$ and routines from Chapters F01 and F04 of the NAG Foundation Library will frequently be useful in this context. In particular, if $A$ is a positive-definite variable band matrix, F04MCF may be used after $A$ has been factorized by F01MCF. Thus factorization need be performed only once prior to calling F02FJF. An illustration of this type of use is given in the example program in Section 9.

An approximation $d_0$, to the $i$th eigenvalue, is accepted as soon as $d_0$ and the previous approximation differ by less than $\frac{|d_0|}{10}$. Eigenvectors are accepted in groups corresponding to clusters of eigenvalues that are equal, or nearly equal, in absolute value and that have already been accepted. If $d_i$ is the last eigenvalue in such a group and we define the residual $r_j$ as

$$ r_j = Cx_j - y $$

where $y$ is the projection of $C x_j$, with respect to $B$, onto the space spanned by $x_1, x_2, \ldots, x_j$ and $x_i$ is the current approximation to the $i$th eigenvector, then the value $f_i$ returned in MONIT is given by

$$ f_i = \max_{i} \frac{||r_j||}{||C x_j||} = \frac{||x - B x||}{||x||} $$

and each vector in the group is accepted as an eigenvector if

$$ (|d| f_i)/(|d| - e) < TOL $$

where $e$ is the current approximation to $|d|$. The values of the $k$ $f_i$ are systematically increased if the convergence criteria

-
i
appear to be too strict. See Rutishauser [4] for further details.

The algorithm implemented by F02FJF differs slightly from SIMITZ
(Nikolai [1]) in that the eigenvalue sub-problem is solved using
the singular value decomposition of the upper triangular matrix R
T
of the Gram-Schmidt factorization of Cx, rather than forming R R
r

9. Example

To find the four eigenvalues of smallest absolute value and
corresponding eigenvectors for the generalized symmetric
eigenvalue problem Ax=(lambda)Bx, where A and B are the 16 by 16
matrices

\[
A = \begin{pmatrix}
1 & a & a & a \\
(1 - a & a & a & a \\
( & a & a & a & a \\
( & a & a & a & a \\
( & a & a & a & a \\
( & a & a & a & a \\
1 & a & a & a & a \\
( & a & a & a & a \\
( & a & a & a & a \\
( & a & a & a & a \\
( & a & a & a & a \\
( & a & a & a & a \\
( & a & a & a & a \\
( & a & a & a & a \\
( & a & a & a & a \\
1 & a & a & a & a
\end{pmatrix}
\]

where a=-
4

\[
B = \begin{pmatrix}
1 & b & b & b \\
( & b & b & b \\
( & b & b & b \\
( & b & b & b \\
( & b & b & b \\
( & b & b & b \\
( & b & b & b \\
( & b & b & b \\
( & b & b & b \\
( & b & b & b \\
( & b & b & b \\
( & b & b & b \\
( & b & b & b \\
( & b & b & b \\
1 & b & b & b & b
\end{pmatrix}
\]
where \( b = - - 2 \)

TOL is taken as 0.0001 and 6 iteration vectors are used. F01MAF is used to factorize the matrix \( A \), prior to calling F02FJF, and F04MAF is used within IMAGE to solve the equations \( Aw = Bz \) for \( w \). Details of the factorization of \( A \) are passed from F01MAF to F04MAF by means of the COMMON block BLOCK1.

Output from MONIT occurs each time ISTATE is non-zero. Note that the required eigenvalues are the reciprocals of the eigenvalues returned by F02FJF.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

Singular value decomposition of a general real matrix

— nagf.ht —

Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details.
The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F02WEF returns all, or part, of the singular value decomposition of a general real matrix.

2. Specification

```fortran
SUBROUTINE F02WEF (M, N, A, LDA, NCOLB, B, LDB, WANTQ, Q, 1  LDQ, SV, WANTP, PT, LDPT, WORK, IFAIL)
INTEGER M, N, LDA, NCOLB, LDB, LDQ, LDPT, IFAIL
DOUBLE PRECISION A(LDA,*), B(LDB,*), Q(LDQ,*), SV(*), PT 1 (LDPT,*), WORK(*)
LOGICAL WANTQ, WANTP
```

3. Description

The m by n matrix A is factorized as

\[ A = QDP \]

where

\[ (S) \]

\[ D = \begin{cases} 
(0), & m > n, \\
S, & m = n, \\
(S \ 0), & m < n,
\end{cases} \]

Q is an m by m orthogonal matrix, P is an n by n orthogonal matrix and S is a min(m,n) by min(m,n) diagonal matrix with non-negative diagonal elements, sv , sv , ..., sv , ordered such that

\[ sv \geq sv \geq \ldots \geq sv \geq 0. \]

The first min(m,n) columns of Q are the left-hand singular vectors of A, the diagonal elements of S are the singular values of A and the first min(m,n) columns of P are the right-hand singular vectors of A.

Either or both of the left-hand and right-hand singular vectors of A may be requested and the matrix C given by
where \( B \) is an \( m \) by \( n_{colb} \) given matrix, may also be requested.

The routine obtains the singular value decomposition by first reducing \( A \) to upper triangular form by means of Householder transformations, from the left when \( m \geq n \) and from the right when \( m < n \). The upper triangular form is then reduced to bidiagonal form by Givens plane rotations and finally the QR algorithm is used to obtain the singular value decomposition of the bidiagonal form.

Good background descriptions to the singular value decomposition are given in Dongarra et al [1], Hammarling [2] and Wilkinson [3] DSVDC.

Note that if \( K \) is any orthogonal diagonal matrix so that

\[
T \quad K K = I,
\]

(so that \( K \) has elements +1 or -1 on the diagonal)

then

\[
T \\
A = (Q K) D (P K)
\]

is also a singular value decomposition of \( A \).

4. References

5. Parameters

1: \( M \)  -- INTEGER

Input

On entry: the number of rows, \( m \), of the matrix \( A \).

Constraint: \( M \geq 0 \).

When \( M = 0 \) then an immediate return is effected.
2:  N -- INTEGER  
   Input  
   On entry: the number of columns, n, of the matrix A.  
   Constraint: N >= 0.  
   
   When N = 0 then an immediate return is effected.  

3:  A(LDA,*) -- DOUBLE PRECISION array  
   Input/Output  
   Note: the second dimension of the array A must be at least  
         max(1,N).  
   On entry: the leading m by n part of the array A must  
         contain the matrix A whose singular value decomposition is  
         required. On exit: if M >= N and WANTQ = .TRUE., then the  
         leading m by n part of A will contain the first n columns of  
         the orthogonal matrix Q.  
   
   If M < N and WANTP = .TRUE., then the leading m by n part of  
   A will contain the first m rows of the orthogonal matrix P .  
   
   If M >= N and WANTQ = .FALSE. and WANTP = .TRUE., then the  
   leading n by n part of A will contain the first n rows of  
   the orthogonal matrix P .  
   
   Otherwise the leading m by n part of A is used as internal  
   workspace.  

4:  LDA -- INTEGER  
   Input  
   On entry:  
   the first dimension of the array A as declared in the  
   (sub)program from which F02WEF is called.  
   Constraint: LDA >= max(1,M).  

5:  NCOLB -- INTEGER  
   Input  
   On entry: ncolb, the number of columns of the matrix B.  
   When NCOLB = 0 the array B is not referenced. Constraint:  
   NCOLB >= 0.  

6:  B(LDB,*) -- DOUBLE PRECISION array  
   Input/Output  
   Note: the second dimension of the array B must be at least  
         max(1,ncolb) On entry: if NCOLB > 0, the leading m by ncolb  
         part of the array B must contain the matrix to be  
         transformed. On exit: B is overwritten by the m by ncolb  
         matrix Q B.  

7:  LDB -- INTEGER  
   Input  
   On entry:  
   the first dimension of the array B as declared in the  
   (sub)program from which F02WEF is called.
Constraint: if NCOLB > 0 then LDB >= max(1,M).

8: WANTQ -- LOGICAL  
   Input 
   On entry: WANTQ must be .TRUE., if the left-hand singular 
vectors are required. If WANTQ = .FALSE., then the array Q 
is not referenced.

9: Q(LDQ,*) -- DOUBLE PRECISION array  
   Output 
   Note: the second dimension of the array Q must be at least 
max(1,M).
   On exit: if M < N and WANTQ = .TRUE., the leading m by m 
part of the array Q will contain the orthogonal matrix Q. 
Otherwise the array Q is not referenced.

10: LDQ -- INTEGER  
    Input 
    On entry: 
    the first dimension of the array Q as declared in the 
(sub)program from which F02WEF is called. 
    Constraint: if M < N and WANTQ = .TRUE., LDQ >= max(1,M).

11: SV(*) -- DOUBLE PRECISION array  
    Output 
    Note: the length of SV must be at least min(M,N). On exit: 
    the min(M,N) diagonal elements of the matrix S.

12: WANTP -- LOGICAL  
    Input 
    On entry: WANTP must be .TRUE. if the right-hand singular 
vectors are required. If WANTP = .FALSE., then the array PT 
is not referenced.

13: PT(LDPT,*) -- DOUBLE PRECISION array  
    Output 
    Note: the second dimension of the array PT must be at least 
max(1,N).
    On exit: if M >= N and WANTQ and WANTP are .TRUE., the 
    leading n by n part of the array PT will contain the 
    orthogonal matrix P . Otherwise the array PT is not 
    referenced.

14: LDPT -- INTEGER  
    Input 
    On entry: 
    the first dimension of the array PT as declared in the 
(sub)program from which F02WEF is called. 
    Constraint: if M >= N and WANTQ and WANTP are .TRUE., LDPT 
    >= max(1,N).

15: WORK(*) -- DOUBLE PRECISION array  
    Output 
    Note: the length of WORK must be at least max(1,lwork), 
    where lwork must be as given in the following table:

M >= N
WANTQ is .TRUE. and WANTP = .TRUE.
2
lwork=max(N +5*(N-1),N+NCOLB,4)

WANTQ = .TRUE. and WANTP = .FALSE.
2
lwork=max(N +4*(N-1),N+NCOLB,4)

WANTQ = .FALSE. and WANTP = .TRUE.
1
lwork=max(3*(N-1),2) when NCOLB = 0
lwork=max(5*(N-1),2) when NCOLB > 0

WANTQ = .FALSE. and WANTP = .FALSE.
1
lwork=max(2*(N-1),2) when NCOLB = 0
lwork=max(3*(N-1),2) when NCOLB > 0

M < N
WANTQ = .TRUE. and WANTP = .TRUE.
2
lwork=max(M +5*(M-1),2)

WANTQ = .TRUE. and WANTP = .FALSE.
1
lwork=max(3*(M-1),1)

WANTQ = .FALSE. and WANTP = .TRUE.
2
lwork=max(M +3*(M-1),2) when NCOLB = 0
lwork=max(M +5*(M-1),2) when NCOLB > 0

WANTQ = .FALSE. and WANTP = .FALSE.
1
lwork=max(2*(M-1),1) when NCOLB = 0
lwork=max(3*(M-1),1) when NCOLB > 0

On exit: WORK(min(M,N)) contains the total number of iterations taken by the R algorithm.

The rest of the array is used as workspace.

16: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).
6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL=-1

One or more of the following conditions holds:
M < 0,
N < 0,
LDA < M,
NCOLB < 0,
LDB < M and NCOLB > 0,
LDQ < M and M < N and WANTQ = .TRUE.,
LDPT < N and M >= N and WANTQ = .TRUE., and WANTP = .TRUE..

IFAIL> 0

The QR algorithm has failed to converge in 50*min(m,n) iterations. In this case SV(1), SV(2),..., SV(IFAIL) may not have been found correctly and the remaining singular values may not be the smallest. The matrix A will nevertheless have been factorized as A=QEP , where the leading min(m,n) by min(m,n) part of E is a bidiagonal matrix with SV(1), SV(2),..., SV(min(m,n)) as the diagonal elements and WORK(1), WORK(2),..., WORK(min(m,n)-1) as the super-diagonal elements.

This failure is not likely to occur.

7. Accuracy

The computed factors Q, D and P satisfy the relation

\[ QDP = A + E, \]

where

\[ \| E \| \leq c(\text{epsilon}) \| A \|, \]

(\text{epsilon}) being the machine precision, c is a modest function of m and n and \( \| \cdot \| \) denotes the spectral (two) norm. Note that
\[ \|A\| = sv . \]

8. Further Comments

Following the use of this routine the rank of \( A \) may be estimated by a call to the INTEGER FUNCTION F06KLF(*). The statement:

\[ \text{IRANK} = \text{F06KLF}(	ext{MIN}(M, N), \text{SV}, 1, \text{TOL}) \]

returns the value \((k-1)\) in IRANK, where \( k \) is the smallest integer for which \( \text{SV}(k) < \text{tol} \times \text{SV}(1) \), where \( \text{tol} \) is the tolerance supplied in TOL, so that IRANK is an estimate of the rank of \( S \) and thus also of \( A \). If TOL is supplied as negative then the machine precision is used in place of TOL.

9. Example

9.1. Example 1

To find the singular value decomposition of the 5 by 3 matrix

\[
\begin{pmatrix}
2.0 & 2.5 & 2.5 \\
2.0 & 2.5 & 2.5 \\
1.6 & -0.4 & 2.8 \\
2.0 & -0.5 & 0.5 \\
1.2 & -0.3 & -2.9 \\
\end{pmatrix}
\]

\( A \) together with the vector \( Q b \) for the vector

\[
\begin{pmatrix}
1.1 \\
0.9 \\
0.6 \\
0.0 \\
-0.8 \\
\end{pmatrix}
\]

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

9.2. Example 2

To find the singular value decomposition of the 3 by 5 matrix

\[
\begin{pmatrix}
2.0 & 2.0 & 1.6 & 2.0 & 1.2 \\
2.5 & 2.5 & -0.4 & -0.5 & -0.3 \\
2.5 & 2.5 & 2.8 & 0.5 & -2.9 \\
\end{pmatrix}
\]

\( A \) together with the vector \( b \) for the vector

\[
\begin{pmatrix}
1.1 \\
0.9 \\
0.6 \\
0.0 \\
-0.8 \\
\end{pmatrix}
\]

The example program is not reproduced here. The source code for
CHAPTER 22. NAG LIBRARY ROUTINES

all example programs is distributed with the NAG Foundation Library software and should be available on-line.

---

Singular value decomposition of a general complex matrix

--- nagf.lht ---

Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F02XEF returns all, or part, of the singular value decomposition of a general complex matrix.

2. Specification

SUBROUTINE F02XEF (M, N, A, NCOLB, B, LDB, WANTQ, Q, 1 LDQ, SV, WANTP, PH, LDPH, RWORK, CWORK, 2 IFAIL)

INTEGER M, N, LDA, NCOLB, LDB, LDQ, LDPH,
1 IFAIL

DOUBLE PRECISION SV(*), RWORK(*)
COMPLEX(KIND=KIND(1.0D0)) A(LDA,*), B(LDB,*), Q(LDQ,*),
1 PH(LDPH,*), CWORK(*)

LOGICAL WANTQ, WANTP
3. Description

The \( m \) by \( n \) matrix \( A \) is factorized as

\[
H \quad A = Q D P,
\]

where

\[
\begin{align*}
(S) \\
D = (0), & \quad m > n, \\
D = S, & \quad m = n, \\
D = (S \ 0), & \quad m < n,
\end{align*}
\]

\( Q \) is an \( m \) by \( m \) unitary matrix, \( P \) is an \( n \) by \( n \) unitary matrix and \( S \) is a \( \min(m,n) \) by \( \min(m,n) \) diagonal matrix with real non-negative diagonal elements, \( s_{1} s_{2} \ldots s_{\min(m,n)} \), ordered such that

\[
s_{1} \geq s_{2} \geq \ldots \geq s_{\min(m,n)} \geq 0.
\]

The first \( \min(m,n) \) columns of \( Q \) are the left-hand singular vectors of \( A \), the diagonal elements of \( S \) are the singular values of \( A \) and the first \( \min(m,n) \) columns of \( P \) are the right-hand singular vectors of \( A \).

Either or both of the left-hand and right-hand singular vectors of \( A \) may be requested and the matrix \( C \) given by

\[
H \quad C = Q B,
\]

where \( B \) is an \( m \) by \( \text{ncolb} \) given matrix, may also be requested.

The routine obtains the singular value decomposition by first reducing \( A \) to upper triangular form by means of Householder transformations, from the left when \( m \geq n \) and from the right when \( m < n \). The upper triangular form is then reduced to bidiagonal form by Givens plane rotations and finally the QR algorithm is used to obtain the singular value decomposition of the bidiagonal form.

Good background descriptions to the singular value decomposition are given in Dongarra et al [1], Hammarling [2] and Wilkinson [3] ZSVDC.
Note that if $K$ is any unitary diagonal matrix so that
\[ HH = I, \]
then
\[ HA = (QK)D(PK) \]
is also a singular value decomposition of $A$.

4. References

5. Parameters

1: $M$ -- INTEGER Input
On entry: the number of rows, $m$, of the matrix $A$. Constraint: $M \geq 0$.
When $M = 0$ then an immediate return is effected.

2: $N$ -- INTEGER Input
On entry: the number of columns, $n$, of the matrix $A$. Constraint: $N \geq 0$.
When $N = 0$ then an immediate return is effected.

3: $A(LDA,*)$ -- COMPLEX(KIND(1.0D)) array Input/Output
Note: the second dimension of the array $A$ must be at least $\text{max}(1,N)$.
On entry: the leading $m$ by $n$ part of the array $A$ must contain the matrix $A$ whose singular value decomposition is required. On exit: if $M \geq N$ and WANTQ = .TRUE., then the leading $m$ by $n$ part of $A$ will contain the first $n$ columns of the unitary matrix $Q$.
If $M < N$ and WANTP = .TRUE., then the leading $m$ by $n$ part of $H$ $A$ will contain the first $m$ rows of the unitary matrix $P$.
If $M$
>= N and WANTQ = .FALSE. and WANTP = .TRUE., then the
leading n by n part of A will contain the first n
H
rows of the unitary matrix P. Otherwise the leading m by n
part of A is used as internal workspace.

4: LDA -- INTEGER Input
   On entry:
   the first dimension of the array A as declared in the
   (sub)program from which F02XEF is called.
   Constraint: LDA >= max(1,M).

5: NCOLB -- INTEGER Input
   On entry: ncolb, the number of columns of the matrix B.
   When NCOLB = 0 the array B is not referenced. Constraint:
   NCOLB >= 0.

6: B(LDB,*) -- COMPLEX(KIND(1.0D)) array Input/Output
   Note: the second dimension of the array B must be at least
   max(1,NCOLB).
   On entry: if NCOLB > 0, the leading m by ncolb part of the
   array B must contain the matrix to be transformed. On exit:
   H
   B is overwritten by the m by ncolb matrix Q B.

7: LDB -- INTEGER Input
   On entry:
   the first dimension of the array B as declared in the
   (sub)program from which F02XEF is called.
   Constraint: if NCOLB > 0, then LDB >= max(1,M).

8: WANTQ -- LOGICAL Input
   On entry: WANTQ must be .TRUE. if the left-hand singular
   vectors are required. If WANTQ = .FALSE. then the array Q is
   not referenced.

9: Q(LDQ,*) -- COMPLEX(KIND(1.0D)) array Output
   Note: the second dimension of the array Q must be at least
   max(1,M).
   On exit: if M < N and WANTQ = .TRUE., the leading m by m
   part of the array Q will contain the unitary matrix Q.
   Otherwise the array Q is not referenced.

10: LDQ -- INTEGER Input
    On entry:
    the first dimension of the array Q as declared in the
    (sub)program from which F02XEF is called.
    Constraint: if M < N and WANTQ = .TRUE., LDQ >= max(1,M).

11: SV(*) -- DOUBLE PRECISION array Output
CHAPTER 22. NAG LIBRARY ROUTINES

Note: the length of SV must be at least min(M,N). On exit: the min(m,n) diagonal elements of the matrix S.

12: WANTP -- LOGICAL Input
On entry: WANTP must be .TRUE. if the right-hand singular vectors are required. If WANTP = .FALSE. then the array PH is not referenced.

13: PH(LDPH,*) -- DOUBLE PRECISION array Output
Note: the second dimension of the array PH must be at least max(1,N).
On exit: if M >= N and WANTQ and WANTP are .TRUE., the leading n by n part of the array PH will contain the unitary matrix P. Otherwise the array PH is not referenced.

14: LDPH -- INTEGER Input
On entry:
the first dimension of the array PH as declared in the (sub)program from which F02XEF is called.
Constraint: if M >= N and WANTQ and WANTP are .TRUE., LDPH >= max(1,N).

15: RWORK(*) -- DOUBLE PRECISION array Output
Note: the length of RWORK must be at least max(1,lrwork), where lrwork must satisfy:
lrwork=2*(min(M,N)-1) when
   NCOLB = 0 and WANTQ and WANTP are .FALSE.,
   NCOLB = 0 and WANTQ = .FALSE. and WANTP = .TRUE., or WANTP = .FALSE. and one or both of NCOLB > 0 and WANTQ = .TRUE.,
lrwork=5*(min(M,N)-1) otherwise.
On exit: RWORK(min(M,N)) contains the total number of iterations taken by the QR algorithm.
The rest of the array is used as workspace.

16: CWORK(*) -- COMPLEX(KIND(1.0D)) array Workspace
Note: the length of CWORK must be at least max(1,lcwork), where lcwork must satisfy:
lcwork=2*N+max(N ,NCOLB) when
   M >= N and WANTQ and WANTP are both .TRUE.
   M >= N and WANTQ and WANTP are both .TRUE.
\[ M \geq N \quad \text{and} \quad \text{WANTQ} = .\text{TRUE.}, \quad \text{but} \quad \text{WANTP} = .\text{FALSE.} \]

\[ \text{lwork} = N + \max(N, \text{NCOLB}) \quad \text{when} \]
\[ M \geq N \quad \text{and} \quad \text{WANTQ} = .\text{FALSE.} \]

2

\[ \text{lwork} = M + M \quad \text{when} \]
\[ M < N \quad \text{and} \quad \text{WANTP} = .\text{TRUE.} \]

\[ \text{lwork} = M \quad \text{when} \]
\[ M < N \quad \text{and} \quad \text{WANTP} = .\text{FALSE.} \]

17: \text{IFAIL} -- \text{INTEGER} \quad \text{Input/Output}

On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL=-1

One or more of the following conditions holds:

\[ M < 0, \]
\[ N < 0, \]
\[ \text{LDA} < M, \]
\[ \text{NCOLB} < 0, \]
\[ \text{LDB} < M \quad \text{and} \quad \text{NCOLB} > 0, \]
\[ \text{LDQ} < M \quad \text{and} \quad M < N \quad \text{and} \quad \text{WANTQ} = .\text{TRUE.}, \]
\[ \text{LDPH} < N \quad \text{and} \quad M \geq N \quad \text{and} \quad \text{WANTQ} = .\text{TRUE.} \quad \text{and} \quad \text{WANTP} = .\text{TRUE.} \]

IFAIL > 0

The QR algorithm has failed to converge in 50*\min(m,n) iterations. In this case SV(1), SV(2),..., SV(IFAIL) may not have been found correctly and the remaining singular values may not be the smallest. The matrix A will nevertheless have \[ H \]
been factorized as $A = QEP$ where the leading $\min(m,n)$ by $\min(m,n)$ part of $E$ is a bidiagonal matrix with $SV(1), SV(2), ..., SV(\min(m,n))$ as the diagonal elements and $RWORK(1), RWORK(2), ..., RWORK(\min(m,n)-1)$ as the super-diagonal elements.

This failure is not likely to occur.

7. Accuracy

The computed factors $Q$, $D$ and $P$ satisfy the relation

$$H = QDP = A + E,$$

where

$$||E|| \leq c(\text{epsilon})||A||,$$

(epsilon) being the machine precision, $c$ is a modest function of $m$ and $n$ and $||.||$ denotes the spectral (two) norm. Note that $||A|| = sv$.

8. Further Comments

Following the use of this routine the rank of $A$ may be estimated by a call to the INTEGER FUNCTION F06KLF(*). The statement:

$$\text{IRANK} = \text{F06KLF}(\min(M, N), SV, 1, \text{TOL})$$

returns the value $(k-1)$ in IRANK, where $k$ is the smallest integer for which $SV(k) < \text{tol} \ast SV(1)$, where tol is the tolerance supplied in TOL, so that IRANK is an estimate of the rank of $S$ and thus also of $A$. If TOL is supplied as negative then the machine precision is used in place of TOL.

9. Example

9.1. Example 1

To find the singular value decomposition of the 5 by 3 matrix

$$A = \begin{pmatrix}
0.5i & -0.5 + 1.5i & -1.0 + 1.0i \\
0.4 + 0.3i & 0.9 + 1.3i & 0.2 + 1.4i \\
0.4 & -0.4 + 0.4i & 1.8 \\
0.3 - 0.4i & 0.1 + 0.7i & 0.0 \\
-0.3i & 0.3 + 0.3i & 2.4i
\end{pmatrix}$$
H
together with the vector Q b for the vector

\[
\begin{bmatrix}
-0.55 + 1.05i \\
0.49 + 0.93i \\
0.56 - 0.16i \\
0.39 + 0.23i \\
1.13 + 0.83i
\end{bmatrix}
\]

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

9.2. Example 2

To find the singular value decomposition of the 3 by 5 matrix

\[
A = \begin{bmatrix}
0.5i & 0.4 - 0.3i & 0.4 & 0.3 + 0.4i & 0.3i \\
-0.5 - 1.5i & 0.9 - 1.3i & -0.4 - 0.4i & 0.1 - 0.7i & 0.3 - 0.3i \\
-1.0 - 1.0i & 0.2 - 1.4i & 1.8 & 0.0 & -2.4i
\end{bmatrix}
\]

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
Simultaneous Linear Equations

1. Scope of the Chapter

This chapter, together with two routines in Chapter F07, is concerned with the solution of the matrix equation $AX = B$, where $B$ may be a single vector or a matrix of multiple right-hand sides. The matrix $A$ may be real, complex, symmetric, Hermitian positive-definite, or sparse. It may also be rectangular, in which case a least-squares solution is obtained.

2. Background to the Problems

A set of linear equations may be written in the form

$$Ax = b$$

where the known matrix $A$, with real or complex coefficients, is of size $m$ by $n$, ($m$ rows and $n$ columns), the known right-hand vector $b$ has $m$ components ($m$ rows and one column), and the required solution vector $x$ has $n$ components ($n$ rows and one column). There may sometimes be $p$ vectors $b_i$, $i=1,2,...,p$ on the right-hand side and the equations may then be written as

$$AX = B$$

the required matrix $X$ having as its $p$ columns the solutions of $Ax = b_i$, $i=1,2,...,p$. Some routines deal with the latter case, but for clarity only the case $p=1$ is discussed here.

The most common problem, the determination of the unique solution of $Ax = b$, occurs when $m=n$ and $A$ is non-singular, that is $\text{rank}(A)=n$ problem, discussed in Section 2.2 below, is the determination of the least-squares solution of $Ax = b$, i.e., the determination of a vector $x$ which minimizes the Euclidean length (two norm) of the residual vector $r = b - Ax$. The usual case has $m>n$ and $\text{rank}(A)=n$, in which case $x$ is unique.

2.1. Unique Solution of $Ax = b$

Most of the routines in this chapter, as well as two routines in Chapter F07, solve this particular problem. The solution is obtained by performing either an LU factorization, or a Cholesky factorization, as discussed in Section 2 of the F01 Chapter Introduction.

Two of the routines in this chapter use a process called iterative refinement to improve the initial solution in order to
obtain a solution that is correct to working accuracy. It should be emphasised that if A and b are not known exactly then not all the figures in this solution may be meaningful. To be more precise, if x is the exact solution of the equations

$$Ax = b$$

and x is the solution of the perturbed equations

$$(A+E)x = b+e,$$

then, provided that $$(\kappa)(A) \leq 1,$$

$$\frac{||x-x||}{||x||} \leq \frac{||E||}{||A||} (||A|| ||b||) (1-(\kappa)(A))^{-1} \leq \frac{||E||}{||A||} (||A|| ||b||),$$

where $$(\kappa)(A) = ||A|| ||A^{-1}||$$ is the condition number of A with respect to inversion. Thus, if A is ill-conditioned ($$(\kappa)(A)$$ is large), x may differ significantly from x. Often $$(||E||)/(||A||)$$ is <<1 in which case the above bound effectively reduces to

$$\frac{||x-x||}{||x||} \leq (\kappa)(A)(||E|| ||e||)/(||A|| ||b||).$$

2.2. The Least-squares Solution of $$Ax = b$$

The least-squares problem is to find a vector x to minimize
When $m \geq n$ and $\text{rank}(A) = n$ then the solution vector $x$ is unique. For the cases where $x$ is not unique the routines in this chapter obtain the minimal length solution, that is the vector $x$ for which $x^T x$ is a minimum.

2.3. Calculating the Inverse of a Matrix

The routines in this chapter can also be used to calculate the inverse of a square matrix $A$ by solving the equation

$$\text{AX} = \text{I},$$

where $\text{I}$ is the identity matrix.

3. Recommendations on Choice and Use of Routines

3.1. General Purpose Routines

Many of the routines in this chapter perform the complete solution of the required equations, but some of the routines, as well as the routines in Chapter F07, assume that a prior factorization has been performed, using the appropriate factorization routine from Chapter F01 or Chapter F07. These, so-called, general purpose routines can be useful when explicit information on the factorization is required, as well as the solution of the equations, or when the solution is required for multiple right-hand sides, or for a sequence of right-hand sides.

Note that some of the routines that perform a complete solution also allow multiple right-hand sides.

3.2. Iterative Refinement

The routines that perform iterative refinement are more costly than those that do not perform iterative refinement, both in terms of time and storage, and should only be used if the problem really warrants the additional accuracy provided by these routines. The storage requirements are approximately doubled, while the additional time is not usually prohibitive since the initial factorization is used at each iteration.

3.3. Sparse Matrix Routines

The routines for sparse matrices should usually be used only when the number of non-zero elements is very small, less than 10% of
the total number of elements of $A$. Additionally, when the matrix is symmetric positive-definite the sparse routines should generally be used only when $A$ does not have a (variable) band structure.

There are four routines for solving sparse linear equations, two for solving general real systems (F04AXF and F04QAF), one for solving symmetric positive-definite systems (F04MAF) and one for solving symmetric systems that may, or may not, be positive-definite (F04MBF). F04AXF and F04MAF utilise factorizations of the matrix $A$ obtained by routines in Chapter F01, while the other two routines use iterative techniques and require a user-supplied function to compute matrix-vector products $Ac$ and $A^Tc$ for any given vector $c$. The routines requiring factorizations will usually be faster and the factorization can be utilised to solve for several right-hand sides, but the original matrix has to be explicitly supplied and is overwritten by the factorization, and the storage requirements will usually be substantially more than those of the iterative routines.

Routines F04MBF and F04QAF both allow the user to supply a preconditioner.

F04MBF can be used to solve systems of the form $(A-(\lambda)I)x=b$, which can be useful in applications such as Rayleigh quotient iteration.

F04QAF also solves sparse least-squares problems and allows the solution of damped (regularized) least-squares problems.

3.4. Decision Trees

If at any stage the answer to a question is 'Don't know' this should be read as 'No'.

For those routines that need to be preceded by a factorization routine, the appropriate routine name is given in brackets after the name of the routine for solving the equations. Note also that you may be directed to a routine in Chapter F07.

3.4.1. Routines for unique solution of $Ax=b$

Approximate solution of a set of complex linear equations

— nagf.ht —

SUBROUTINE F04ADF (A, IA, B, IB, N, M, C, IC, WKSPCE, IFAIL)
INTEGER IA, IB, N, M, IC, IFAIL
DOUBLE PRECISION WKSPCE(*)
COMPLEX(KIND(1.0D0)) A(IA,*), B(IB,*), C(IC,*)

Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F04ADF calculates the approximate solution of a set of complex linear equations with multiple right-hand sides, using an LU factorization with partial pivoting.

2. Specification

SUBROUTINE F04ADF (A, IA, B, IB, N, M, C, IC, WKSPCE, IFAIL)
INTEGER IA, IB, N, M, IC, IFAIL
DOUBLE PRECISION WKSPCE(*)
COMPLEX(KIND(1.0D0)) A(IA,*), B(IB,*), C(IC,*)

3. Description

Given a set of complex linear equations AX=B, the routine first computes an LU factorization of A with partial pivoting, PA=LU, where P is a permutation matrix, L is lower triangular and U is unit upper triangular. The columns x of the solution X are found by forward and backward substitution in Ly=Pb and Ux=y, where b
is a column of the right-hand side matrix B.

4. References

5. Parameters

1: A(IA,*) -- COMPLEX(KIND(1.0D)) array Input/Output
   Note: the second dimension of the array A must be at least max(1,N).
   On entry: the n by n matrix A. On exit: A is overwritten by the lower triangular matrix L and the off-diagonal elements of the upper triangular matrix U. The unit diagonal elements of U are not stored.

2: IA -- INTEGER Input
   On entry:
   the first dimension of the array A as declared in the (sub)program from which F04ADF is called.
   Constraint: IA >= max(1,N).

3: B(IB,*) -- COMPLEX(KIND(1.0D)) array Input
   Note: the second dimension of the array B must be at least max(1,M).
   On entry: the n by m right-hand side matrix B. See also Section 8.

4: IB -- INTEGER Input
   On entry:
   the first dimension of the array B as declared in the (sub)program from which F04ADF is called.
   Constraint: IB >= max(1,N).

5: N -- INTEGER Input
   On entry: n, the order of the matrix A. Constraint: N >= 0.

6: M -- INTEGER Input
   On entry: m, the number of right-hand sides. Constraint: M >= 0.

7: C(IC,*) -- COMPLEX(KIND(1.0D)) array Output
   Note: the second dimension of the array C must be at least max(1,M).
   On exit: the n by m solution matrix X. See also Section 8.

8: IC -- INTEGER Input
   On entry:
   the first dimension of the array C as declared in the
(sub)program from which F04ADF is called. 
Constraint: IC >= max(1,N).

9: WKSPCE(*) -- DOUBLE PRECISION array
   Workspace
   Note: the dimension of the array WKSPCE must be at least 
   max(1,N).

10: IFAIL -- INTEGER
    Input/Output
    On entry: IFAIL must be set to 0, -1 or 1. For users not 
    familiar with this parameter (described in the Essential 
    Introduction) the recommended value is 0.
    
    On exit: IFAIL = 0 unless the routine detects an error (see 
    Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are 
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
   The matrix A is singular, possibly due to rounding errors.

IFAIL= 2
   On entry N < 0,
   or M < 0,
   or IA < max(1,N),
   or IB < max(1,N),
   or IC < max(1,N).

7. Accuracy

The accuracy of the computed solution depends on the conditioning 
of the original matrix. For a detailed error analysis see 

8. Further Comments

The time taken by the routine is approximately proportional to n

Unless otherwise stated in the Users' Note for your 
implementation, the routine may be called with the same actual 
array supplied for parameters B and C, in which case the solution
vectors will overwrite the right-hand sides. However this is not standard Fortran 77, and may not work on all systems.

9. Example

To solve the set of linear equations $AX=B$ where

\[
A = \begin{pmatrix}
1 & 1+2i & 2+10i \\
1+i & 3i & -5+14i \\
1+i & 5i & -8+20i
\end{pmatrix}
\]

and

\[
B = \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}
\]

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

Approximate solution of a set of real linear equations

— nagf.ht —

Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details.
The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F04ARF calculates the approximate solution of a set of real linear equations with a single right-hand side, using an LU factorization with partial pivoting.

2. Specification

```fortran
SUBROUTINE F04ARF (A, IA, B, N, C, WKSPCE, IFAIL)
INTEGER IA, N, IFAIL
DOUBLE PRECISION A(IA,*), B(*), C(*), WKSPCE(*)
```

3. Description

Given a set of linear equations, \( Ax=b \), the routine first computes an LU factorization of \( A \) with partial pivoting, \( PA=LU \), where \( P \) is a permutation matrix, \( L \) is lower triangular and \( U \) is unit upper triangular. The approximate solution \( x \) is found by forward and backward substitution in \( Ly=Pb \) and \( Ux=y \), where \( b \) is the right-hand side.

4. References

5. Parameters

1: \( A(IA,*) \) -- DOUBLE PRECISION array
   Input/Output
   Note: the second dimension of the array \( A \) must be at least \( \max(1,N) \).
   On entry: the \( n \) by \( n \) matrix \( A \). On exit: \( A \) is overwritten by the lower triangular matrix \( L \) and the off-diagonal elements of the upper triangular matrix \( U \). The unit diagonal elements of \( U \) are not stored.

2: \( IA \) -- INTEGER
   Input
   On entry: the first dimension of the array \( A \) as declared in the (sub)program from which F04ARF is called.
   Constraint: \( IA \geq \max(1,N) \).

3: \( B(*) \) -- DOUBLE PRECISION array
   Input
   Note: the dimension of the array \( B \) must be at least \( \max(1,N) \).
   On entry: the right-hand side vector \( b \).
4: N -- INTEGER  
   Input
   On entry: n, the order of the matrix A. Constraint: N >= 0.

5: C(*) -- DOUBLE PRECISION array  
   Output
   Note: the dimension of the array C must be at least
   max(1,N).
   On exit: the solution vector x.

6: WKSPCE(*) -- DOUBLE PRECISION array  
   Workspace
   Note: the dimension of the array WKSPCE must be at least
   max(1,N).

7: IFAIL -- INTEGER  
   Input/Output
   On entry: IFAIL must be set to 0, -1 or 1. For users not
   familiar with this parameter (described in the Essential
   Introduction) the recommended value is 0.
   On exit: IFAIL = 0 unless the routine detects an error (see
   Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
   The matrix A is singular, possibly due to rounding errors.

IFAIL= 2
   On entry N < 0,
   or IA < max(1,N).

7. Accuracy

The accuracy of the computed solution depends on the conditioning
of the original matrix. For a detailed error analysis see

8. Further Comments

The time taken by the routine is approximately proportional to n

Unless otherwise stated in the Users' Note for your
implementation, the routine may be called with the same actual
array supplied for parameters B and C, in which case the solution
vector will overwrite the right-hand side. However this is not
standard Fortran 77, and may not work on all systems.

9. Example

To solve the set of linear equations $Ax=b$ where

$$
A = \begin{pmatrix}
33 & 16 & 72 \\
-24 & -10 & -57 \\
-8 & -4 & -17
\end{pmatrix}
$$

and

$$
b = \begin{pmatrix}
-359 \\
281 \\
85
\end{pmatrix}
$$

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
not included in the Foundation Library.

1. Purpose

F04ASF calculates the accurate solution of a set of real symmetric positive-definite linear equations with a single right-hand side, $Ax=b$, using a Cholesky factorization and iterative refinement.

2. Specification

```fortran
SUBROUTINE F04ASF (A, IA, B, N, C, WK1, WK2, IFAIL)
    INTEGER IA, N, IFAIL
    DOUBLE PRECISION A(IA,*), B(*), C(*), WK1(*), WK2(*)
```

3. Description

Given a set of real linear equations $Ax=b$, where $A$ is a symmetric positive-definite matrix, the routine first computes a Cholesky factorization of $A$ as $A=LL^T$ where $L$ is lower triangular. An approximation to $x$ is found by forward and backward substitution. The residual vector $r=b-Ax$ is then calculated using additional precision and a correction $d$ to $x$ is found by solving $LL^Td=r$. $x$ is then replaced by $x+d$, and this iterative refinement of the solution is repeated until machine accuracy is obtained.

4. References

5. Parameters

1: $A(IA,*)$ -- DOUBLE PRECISION array Input/Output
   Note: the second dimension of the array $A$ must be at least max(1,N).
   On entry: the upper triangle of the $n$ by $n$ positive-definite symmetric matrix $A$. The elements of the array below the diagonal need not be set. On exit: the elements of the array below the diagonal are overwritten; the upper triangle of $A$ is unchanged.

2: $IA$ -- INTEGER Input
   On entry: the first dimension of the array $A$ as declared in the (sub)program from which F04ASF is called.
   Constraint: $IA >= max(1,N)$. 

3: B(*) -- DOUBLE PRECISION array Input
Note: the dimension of the array B must be at least max(1,N).
On entry: the right-hand side vector b.

4: N -- INTEGER Input
On entry: n, the order of the matrix A. Constraint: N >= 0.

5: C(*) -- DOUBLE PRECISION array Output
Note: the dimension of the array C must be at least max(1,N).
On exit: the solution vector x.

6: WK1(*) -- DOUBLE PRECISION array Workspace
Note: the dimension of the array WK1 must be at least max(1,N).

7: WK2(*) -- DOUBLE PRECISION array Workspace
Note: the dimension of the array WK2 must be at least max(1,N).

8: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1
The matrix A is not positive-definite, possibly due to rounding errors.

IFAIL= 2
Iterative refinement fails to improve the solution, i.e., the matrix A is too ill-conditioned.

IFAIL= 3
On entry N < 0,
or IA < max(1,N).

7. Accuracy
The computed solutions should be correct to full machine accuracy. For a detailed error analysis see Wilkinson and Reinsch [1] page 39.

8. Further Comments

The time taken by the routine is approximately proportional to n

The routine must not be called with the same name for parameters B and C.

9. Example

To solve the set of linear equations \( Ax=b \) where

\[
\begin{pmatrix}
5 & 7 & 6 & 5 \\
7 & 10 & 8 & 7 \\
6 & 8 & 10 & 9 \\
5 & 7 & 9 & 10
\end{pmatrix}
\]

and

\[
\begin{pmatrix}
23 \\
32 \\
33 \\
31
\end{pmatrix}
\]

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
F04ATF calculates the accurate solution of a set of real linear equations with a single right-hand side, using an LU factorization with partial pivoting, and iterative refinement.

2. Specification

```fortran
SUBROUTINE F04ATF (A, IA, B, N, C, AA, IAA, WKS1, WKS2, IFAIL)
    INTEGER IA, N, IAA, IFAIL
    DOUBLE PRECISION A(IA,*), B(*), C(*), AA(IAA,*), WKS1(*), WKS2(*)
```

3. Description

Given a set of real linear equations, $Ax=b$, the routine first computes an LU factorization of $A$ with partial pivoting, $PA=LU$, where $P$ is a permutation matrix, $L$ is lower triangular and $U$ is unit upper triangular. An approximation to $x$ is found by forward and backward substitution in $Ly=Pb$ and $Ux=y$. The residual vector $r=b-Ax$ is then calculated using additional precision, and a correction $d$ to $x$ is found by solving $LUd=r$. $x$ is replaced by $x+d$, and this iterative refinement of the solution is repeated until full machine accuracy is obtained.

4. References

5. Parameters

1. $A(IA,*)$ -- DOUBLE PRECISION array Input
   Note: the second dimension of the array $A$ must be at least
max(1,N).
On entry: the n by n matrix A.

2: IA -- INTEGER  
Input
On entry:  
the first dimension of the array A as declared in the  
(sub)program from which F04ATF is called.  
Constraint: IA >= max(1,N).

3: B(*) -- DOUBLE PRECISION array  
Input
Note: the dimension of the array B must be at least  
max(1,N).
On entry: the right-hand side vector b.

4: N -- INTEGER  
Input
On entry: n, the order of the matrix A. Constraint: N >= 0.

5: C(*) -- DOUBLE PRECISION array  
Output
Note: the dimension of the array C must be at least  
max(1,N).
On exit: the solution vector x.

6: AA(IAA,*) -- DOUBLE PRECISION array  
Output
Note: the second dimension of the array AA must be at least  
max(1,N).
On exit: the triangular factors L and U, except that the  
unit diagonal elements of U are not stored.

7: IAA -- INTEGER  
Input
On entry:  
the first dimension of the array AA as declared in the  
(sub)program from which F04ATF is called.  
Constraint: IAA >= max(1,N).

8: WKS1(*) -- DOUBLE PRECISION array  
Workspace
Note: the dimension of the array WKS1 must be at least  
max(1,N).

9: WKS2(*) -- DOUBLE PRECISION array  
Workspace
Note: the dimension of the array WKS2 must be at least  
max(1,N).

10: IFAIL -- INTEGER  
Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not  
familiar with this parameter (described in the Essential  
Introduction) the recommended value is 0.  
On exit: IFAIL = 0 unless the routine detects an error (see  
Section 6).
6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL = 1
The matrix A is singular, possibly due to rounding errors.

IFAIL = 2
Iterative refinement fails to improve the solution, i.e., the matrix A is too ill-conditioned.

IFAIL = 3
On entry N < 0,

or IA < max(1,N),

or IAA < max(1,N).

7. Accuracy

The computed solutions should be correct to full machine accuracy. For a detailed error analysis see Wilkinson and Reinsch [1] page 107.

8. Further Comments

The time taken by the routine is approximately proportional to n

The routine must not be called with the same name for parameters B and C.

9. Example

To solve the set of linear equations Ax=b where

\[
A = \begin{pmatrix}
33 & 16 & 72 \\
-24 & -10 & -57 \\
-8 & -4 & -17
\end{pmatrix}
\]

and

\[
b = \begin{pmatrix}
-359 \\
281 \\
85
\end{pmatrix}
\]
Solution of a set of real sparse linear equations

— nagf.ht —

SUBROUTINE F04AXF (N, A, LICN, ICN, IKEEP, RHS, W, MTYPE,  
1      IDISP, RESID)
    INTEGER N, LICN, ICN(LICN), IKEEP(5*N), MTYPE,  
1      IDISP(2)
    DOUBLE PRECISION A(LICN), RHS(N), W(N), RESID

F04AXF calculates the approximate solution of a set of real sparse linear equations with a single right-hand side, $Ax=b$ or $T^{-1}Ax=b$, where $A$ has been factorized by F01BRF or F01BSF.
3. Description

To solve a system of real linear equations $Ax=b$ or $x=b$, where $A$ is a general sparse matrix, $A$ must first be factorized by F01BRF or F01BSF. F04AXF then computes $x$ by block forward or backward substitution using simple forward and backward substitution within each diagonal block.

The method is fully described in Duff [1].

4. References

5. Parameters

1: N -- INTEGER Input
On entry: $n$, the order of the matrix $A$.

2: A(LICN) -- DOUBLE PRECISION array Input
On entry: the non-zero elements in the factorization of the matrix $A$, as returned by F01BRF or F01BSF.

3: LICN -- INTEGER Input
On entry: the dimension of the arrays A and ICN as declared in the (sub)program from which F04AXF is called.

4: ICN(LICN) -- INTEGER array Input
On entry: the column indices of the non-zero elements of the factorization, as returned by F01BRF or F01BSF.

5: IKEEP(5*N) -- INTEGER array Input
On entry: the indexing information about the factorization, as returned by F01BRF or F01BSF.

6: RHS(N) -- DOUBLE PRECISION array Input/Output
On entry: the right-hand side vector $b$. On exit: RHS is overwritten by the solution vector $x$.

7: W(N) -- DOUBLE PRECISION array Workspace

8: MTYPE -- INTEGER Input
On entry: MTYPE specifies the task to be performed:
   if MTYPE = 1, solve $Ax=b$,
if MTYPE /= 1, solve A x=b.

9: IDISP(2) -- INTEGER array
   Input
   On entry: the values returned in IDISP by F01BRF.

10: RESID -- DOUBLE PRECISION
    Output
    On exit: the value of the maximum residual,
    --
    max(|b - a x |), over all the unsatisfied equations, in
    i -- ij j
    case F01BRF or F01BSF has been used to factorize a singular
    or rectangular matrix.

6. Error Indicators and Warnings

None.

7. Accuracy

The accuracy of the computed solution depends on the conditioning
of the original matrix. Since F04AXF is always used with either
F01BRF or F01BSF, the user is recommended to set GROW = .TRUE. on
entry to these routines and to examine the value of W(1) on exit
(see the routine documents for F01BRF and F01BSF). For a detailed
error analysis see Duff [1] page 17.

If storage for the original matrix is available then the error
can be estimated by calculating the residual

\[ T \]
\[ r=b-Ax \quad (or \ b-Ax) \]

and calling F04AXF again to find a correction (delta) for x by
solving

\[ T \]
\[ A(delta)=r \quad (or \ A(delta)=r). \]

8. Further Comments

If the factorized form contains (tau) non-zeros (IDISP(2) = (tau)
) then the time taken is very approximately 2(tau) times longer
than the inner loop of full matrix code. Some advantage is taken
of zeros in the right-hand side when solving A x=b (MTYPE /= 1).

9. Example
To solve the set of linear equations $Ax=b$ where

$$
\begin{pmatrix}
5 & 0 & 0 & 0 & 0 \\
0 & 2 & -1 & 2 & 0 \\
0 & 0 & 3 & 0 & 0 \\
-2 & 0 & 0 & 1 & 1 \\
-1 & 0 & -1 & 2 & -3 \\
-1 & -1 & 0 & 0 & 6
\end{pmatrix}
$$

and

$$
\begin{pmatrix}
15 \\
12 \\
18 \\
3 \\
-6 \\
0
\end{pmatrix}
$$

The non-zero elements of $A$ and indexing information are read in by the program, as described in the document for F01BRF.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
F04FAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F04FAF calculates the approximate solution of a set of real symmetric positive-definite tridiagonal linear equations.

2. Specification

```fortran
SUBROUTINE F04FAF (JOB, N, D, E, B, IFAIL)
INTEGER JOB, N, IFAIL
DOUBLE PRECISION D(N), E(N), B(N)
```

3. Description

F04FAF is based upon the Linpack routine DPTSL (see Dongarra et al [1]) and solves the equations

\[ T x = b, \]

where \( T \) is a real \( n \) by \( n \) symmetric positive-definite tridiagonal matrix, using a modified symmetric Gaussian elimination algorithm

\[ T = K M K, \]

where \( K \) is diagonal and \( M \) is a matrix of multipliers as described in Section 8.

When the input parameter JOB is supplied as 1, then the routine assumes that a previous call to F04FAF has already factorized \( T \); otherwise JOB must be supplied as 0.

4. References

LINPACK Users' Guide. SIAM, Philadelphia.

5. Parameters

1: JOB -- INTEGER

On entry: specifies the job to be performed by F04FAF as follows:

\( \text{JOB} = 0 \)

The matrix \( T \) is factorized and the equations \( T x = b \) are solved for \( x \).

\( \text{JOB} = 1 \)
The matrix $T$ is assumed to have already been factorized by a previous call to F04FAF with $JOB = 0$; the equations $Tx=b$ are solved for $x$.

2: $N$ -- INTEGER  \hspace{1cm} \text{Input}
On entry: $n$, the order of the matrix $T$. Constraint: $N \geq 1$.

3: $D(N)$ -- DOUBLE PRECISION array  \hspace{1cm} \text{Input/Output}
On entry: if $JOB = 0$, $D$ must contain the diagonal elements of $T$. If $JOB = 1$, $D$ must contain the diagonal matrix $K$, as returned by a previous call of F04FAF with $JOB = 0$. On exit: if $JOB = 0$, $D$ is overwritten by the diagonal matrix $K$ of the factorization. If $JOB = 1$, $D$ is unchanged.

4: $E(N)$ -- DOUBLE PRECISION array  \hspace{1cm} \text{Input/Output}
On entry: if $JOB = 0$, $E$ must contain the super-diagonal elements of $T$, stored in $E(2)$ to $E(n)$. If $JOB = 1$, $E$ must contain the off-diagonal elements of the matrix $M$, as returned by a previous call of F04FAF with $JOB = 0$. $E(1)$ is not used. On exit: if $JOB = 0$, $E(2)$ to $E(n)$ are overwritten by the off-diagonal elements of the matrix $M$ of the factorization. If $JOB = 1$, $E$ is unchanged.

5: $B(N)$ -- DOUBLE PRECISION array  \hspace{1cm} \text{Input/Output}
On entry: the right-hand side vector $b$. On exit: $B$ is overwritten by the solution vector $x$.

6: $IFAIL$ -- INTEGER  \hspace{1cm} \text{Input/Output}
On entry: $IFAIL$ must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: $IFAIL = 0$ unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

$IFAIL=1$
On entry $N < 1$,

or \hspace{1cm} $JOB \neq 0$ or 1.

$IFAIL=2$
The matrix $T$ is either not positive-definite or is nearly singular. This failure can only occur when $JOB = 0$ and inspection of the elements of $D$ will give an indication of why failure has occurred. If an element of $D$ is close to zero, then $T$ is probably nearly singular; if an element of $D$
is negative but not close to zero, then $T$ is not positive-definite.

**IFAILOverflow**
If overflow occurs during the execution of this routine, then either $T$ is very nearly singular or an element of the right-hand side vector $b$ is very large. In this latter case the equations should be scaled so that no element of $b$ is very large. Note that to preserve symmetry it is necessary to scale by a transformation of the form $(PTP)b=Px$, where $P$ is a diagonal matrix.

**IFAILUnderflow**
Any underflows that occur during the execution of this routine are harmless.

7. Accuracy

The computed factorization (see Section 8) will satisfy the equation

$$MKM = T + E$$

where $\|E\| \leq 2(\varepsilon)\|T\|$, $p=1,F,\infty$, $p$,

$(\varepsilon)$ being the machine precision. The computed solution of the equations $Tx=b$, say $x$, will satisfy an equation of the form

$$(T+F)x=b,$$

where $F$ can be expected to satisfy a bound of the form

$$\|F\| \leq (\alpha)(\varepsilon)\|T\|,$$

$(\alpha)$ being a modest constant. This implies that the relative error in $x$ satisfies

$$\frac{\|x-x\|}{\|x\|} \leq c(T)(\alpha)(\varepsilon),$$
where $c(T)$ is the condition number of $T$ with respect to inversion. Thus if $T$ is nearly singular, $x$ can be expected to have a large relative error.

8. Further Comments

The time taken by the routine is approximately proportional to $n$.

The routine eliminates the off-diagonal elements of $T$ by simultaneously performing symmetric Gaussian elimination from the top and the bottom of $T$. The result is that $T$ is factorized as

$$
\begin{align*}
T &= MKM ,
\end{align*}
$$

where $K$ is a diagonal matrix and $M$ is a matrix of the form

$$
\begin{pmatrix}
1 & 0 & 0 & \ldots & 0 & 0 & 0 & \ldots & 0 & 0 \\
1 & 0 & 0 & \ldots & 0 & 0 & 0 & \ldots & 0 & 0 \\
2 & & & & & & & & & \\
0 & m & 1 & \ldots & 0 & 0 & 0 & \ldots & 0 & 0 \\
3 & & & & & & & & & \\
( & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & ) \\
( & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & ) \\
( & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & ) \\
0 & 0 & 0 & \ldots & 1 & 0 & 0 & \ldots & 0 & 0 & 0 \\
M &= (0 & 0 & 0 & \ldots & m & 1 & m & \ldots & 0 & 0 & 0) \\
( & j+1 & j+2 & & & & & & & & \\
0 & 0 & 0 & \ldots & 0 & 0 & \ldots & 1 & 0 & 0 & 0) \\
( & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & ) \\
( & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & \ldots & ) \\
0 & 0 & 0 & \ldots & 0 & 0 & 0 & \ldots & 1 & m & 0) \\
( & & & & & & & & & & n-1) \\
0 & 0 & 0 & \ldots & 0 & 0 & 0 & \ldots & 0 & 1 & m) \\
( & & & & & & & & & & n) \\
0 & 0 & 0 & \ldots & 0 & 0 & 0 & \ldots & 0 & 0 & 1)
\end{pmatrix}
$$

$j$ being the integer part of $n/2$. (For example when $n=5, j=2$.) The diagonal elements of $K$ are returned in $D$ with $k$ in the $i$th element of $D$ and $m$ is returned in the $i$th element of $E$.

The routine fails with $IFAIL = 2$ if any diagonal element of $K$ is non-positive. It should be noted that $T$ may be nearly singular even if all the diagonal elements of $K$ are positive, but in this case at least one element of $K$ is almost certain to be small.
relative to $|||T|||$. If there is any doubt as to whether or not $T$ is nearly singular, then the user should consider examining the diagonal elements of $K$.

9. Example

To solve the symmetric positive-definite equations

$$Tx = b$$

1 1

and

$$Tx = b$$

2 2

where

$$T = \begin{pmatrix}
 4 & -2 & 0 & 0 & 0 \\
-2 & 10 & -6 & 0 & 0 \\
0 & -6 & 29 & 15 & 0 \\
0 & 0 & 15 & 25 & 8 \\
0 & 0 & 0 & 8 & 5
\end{pmatrix}, \quad b = \begin{pmatrix}
6 \\
9 \\
10 \\
4 \\
2
\end{pmatrix}$$

The equations are solved by two calls to F04FAF, the first with JOB = 0 and the second, using the factorization from the first call, with JOB = 1.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
1. Purpose

F04JGF finds the solution of a linear least-squares problem, \( Ax = b \), where \( A \) is a real \( m \) by \( n \) (\( m \geq n \)) matrix and \( b \) is an \( m \) element vector. If the matrix of observations is not of full rank, then the minimal least-squares solution is returned.

2. Specification

```
SUBROUTINE F04JGF (M, N, A, NRA, B, TOL, SVD, SIGMA,
                   IRANK, WORK, LWORK, IFAIL)
INTEGER M, N, NRA, IRANK, LWORK, IFAIL
DOUBLE PRECISION A(NRA,N), B(M), TOL, SIGMA, WORK(LWORK)
LOGICAL SVD
```

3. Description

The minimal least-squares solution of the problem \( Ax = b \) is the vector \( x \) of minimum (Euclidean) length which minimizes the length of the residual vector \( r = b - Ax \).

The real \( m \) by \( n \) (\( m \geq n \)) matrix \( A \) is factorized as

\[
A = Q(0)^T \begin{pmatrix} U \\ 0 \end{pmatrix}
\]

where \( Q \) is an \( m \) by \( m \) orthogonal matrix and \( U \) is an \( n \) by \( n \) upper triangular matrix. If \( U \) is of full rank, then the least-squares solution is given by

\[
x = (U^T 0) Q^{-1} b.
\]

If \( U \) is not of full rank, then the singular value decomposition of \( U \) is obtained so that \( U \) is factorized as

\[
U = Q(0) \Sigma R(0)
\]
U=RDP ,

where R and P are n by n orthogonal matrices and D is the n by n diagonal matrix

$$D = \text{diag}((\sigma_1), (\sigma_2), \ldots, (\sigma_n)),$$

with $\sigma_1 \geq \sigma_2 \geq \ldots \geq \sigma_n \geq 0$, these being the singular values of A. If the singular values $(\sigma_1), \ldots, (\sigma_k)$ are negligible, but $(\sigma_{k+1})$ is not negligible, relative to the data errors in A, then the rank of A is taken to be k and the minimal least-squares solution is given by

$$x = P(0 \ 0 \ 0 \ I )Qb,$$

where $S = \text{diag}((\sigma_1), (\sigma_2), \ldots, (\sigma_k))$.

This routine obtains the factorizations by a call to F02WDF(*).

The routine also returns the value of the standard error

$$\sqrt{\frac{\sigma_k}{m-k}}$$

if $m > k$, $r = 0$ if $m = k$, $r$ being the residual sum of squares and $k$ the rank of A.

4. References

5. Parameters

1: M -- INTEGER Input
   On entry: m, the number of rows of A. Constraint: M >= N.

2: N -- INTEGER Input
   On entry: n, the number of columns of A. Constraint: 1 <= N.
3: A(NRA,N) -- DOUBLE PRECISION array
On entry: the m by n matrix A. On exit: if SVD is returned as .FALSE., A} is overwritten by details of the QU factorization of A (see F02WDF(*) for further details). If SVD is returned as .TRUE., the first n rows of A are overwritten by the right-hand singular vectors, stored by rows; and the remaining rows of the array are used as workspace.

4: NRA -- INTEGER
On entry: the first dimension of the array A as declared in the (sub)program from which F04JGF is called.
Constraint: NRA >= M.

5: B(M) -- DOUBLE PRECISION array
On entry: the right-hand side vector b. On exit: the first n elements of B contain the minimal least-squares solution vector x. The remaining m-n elements are used for workspace.

6: TOL -- DOUBLE PRECISION
On entry: a relative tolerance to be used to determine the rank of A. TOL should be chosen as approximately the largest relative error in the elements of A. For example, if the elements of A are correct to about 4 significant figures \(10^{-4}\), then TOL should be set to about \(5 \times 10^{-10}\). See Section 8 for a description of how TOL is used to determine rank. If TOL is outside the range \(((\text{epsilon}),1.0)\), where \((\text{epsilon})\) is the machine precision, then the value \((\text{epsilon})\) is used in place of TOL. For most problems this is unreasonably small.

7: SVD -- LOGICAL
On exit: SVD is returned as .FALSE. if the least-squares solution has been obtained from the QU factorization of A. In this case A is of full rank. SVD is returned as .TRUE. if the least-squares solution has been obtained from the singular value decomposition of A.

8: SIGMA -- DOUBLE PRECISION
On exit: the standard error, i.e., the value \(\sqrt{r/(m-k)}\) when \(m>k\), and the value zero when \(m=k\). Here \(r\) is the residual vector \(b-Ax\) and \(k\) is the rank of A.

9: IRANK -- INTEGER
On exit: the standard error, i.e., the value \(\sqrt{r/(m-k)}\) when \(m>k\), and the value zero when \(m=k\). Here \(r\) is the residual vector \(b-Ax\) and \(k\) is the rank of A.
On exit: k, the rank of the matrix A. It should be noted that it is possible for IRANK to be returned as n and SVD to be returned as .TRUE.. This means that the matrix U only just failed the test for non-singularity.

10: WORK(LWORK) -- DOUBLE PRECISION array Output
On exit: if SVD is returned as .FALSE., then the first n elements of WORK contain information on the QU factorization of A (see parameter A above and F02WDF(*)), and WORK(n+1)
-1
contains the condition number \[ ||U|| \|U\| \] of the upper triangular matrix U.

If SVD is returned as .TRUE., then the first n elements of WORK contain the singular values of A arranged in descending order and WORK(n+1) contains the total number of iterations taken by the QR algorithm. The rest of WORK is used as workspace.

11: LWORK -- INTEGER Input
On entry:
the dimension of the array WORK as declared in the (sub)program from which F04JGF is called.
Constraint: LWORK >= 4*N.

12: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
On entry N < 1,
or M < N,
or NRA < M,
or LWORK < 4*N.

IFAIL= 2
The QR algorithm has failed to converge to the singular values in 50*N iterations. This failure can only happen when
the singular value decomposition is employed, but even then
it is not likely to occur.

7. Accuracy

\[ T \]

The computed factors \( Q, U, R, D \) and \( P \) satisfy the relations

\[
(U) \quad (R \ 0)(D) \quad T
\]

\[
Q(0)=A+E, \quad Q(0 \ 1)(0)P=A+F,
\]

where

\[
||E|| \leq c(\epsilon)||A||,
\]

\[
2 \ 1 \ 2
\]

\[
||F|| \leq c(\epsilon)||A||,
\]

\[
2 \ 2 \ 2
\]

(\( \epsilon \)) being the machine precision, and \( c \) and \( c \) being modest

\[
1 \quad 2
\]

functions of \( m \) and \( n \). Note that \( ||A|| = (\sigma) \).

\[
2 \quad 1
\]

For a fuller discussion, covering the accuracy of the solution \( x \)
see Lawson and Hanson [1], especially pp 50 and 95.

8. Further Comments

If the least-squares solution is obtained from the QU
factorization then the time taken by the routine is approximately

\[
2
\]

proportional to \( n \ (3m-n) \). If the least-squares solution is
obtained from the singular value decomposition then the time

\[
2
\]

taken is approximately proportional to \( n \ (3m+19n) \). The
approximate proportionality factor is the same in each case.

This routine is column biased and so is suitable for use in paged
environments.

Following the QU factorization of \( A \) the condition number

\[
c(U) = ||U|| \ ||U^{-1}||
\]

\[
E \quad E
\]

is determined and if \( c(U) \) is such that
then $U$ is regarded as singular and the singular values of $A$ are computed. If this test is not satisfied, $U$ is regarded as non-singular and the rank of $A$ is set to $n$. When the singular values are computed the rank of $A$, say $k$, is returned as the largest integer such that

$$\frac{\sigma_i}{\sigma_1} > TOL \cdot \frac{\sigma_1}{\sigma_i}$$

unless $(\sigma_i) = 0$ in which case $k$ is returned as zero. That is, singular values which satisfy $(\sigma_i) \leq TOL \cdot (\sigma_1)$ are regarded as negligible because relative perturbations of order $TOL$ can make such singular values zero.

9. Example

To obtain a least-squares solution for $r=b-Ax$, where

$$\begin{pmatrix} 0.05 & 0.05 & 0.25 & -0.25 \\ 0.25 & 0.25 & 0.05 & -0.05 \\ 0.35 & 0.35 & 1.75 & -1.75 \end{pmatrix}, \quad B= \begin{pmatrix} 1.75 & 1.75 & 0.35 & -0.35 \\ 0.30 & -0.30 & 0.30 & 0.30 \\ 0.40 & -0.40 & 0.40 & 0.40 \end{pmatrix}$$

and the value $TOL$ is to be taken as $5 \times 10^{-4}$. The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

Sparse symmetric positive-definite system linear equations

— nagf.h —
2. Specification

SUBROUTINE F04MAF (N, NZ, A, LICN, IRN, LIRN, ICN, B, ACC,
1       NOITS, WKEEP, WORK, IKEEP, INFORM,
2       IFAIL)
INTEGER N, NZ, LICN, IRN(LIRN), LIRN, ICN(LICN),
1      NOITS(2), IKEEP(2*N), INFORM(4), IFAIL
DOUBLE PRECISION A(LICN), B(N), ACC(2), WKEEP(3*N), WORK
1      (3*N)

3. Description

F04MAF solves the n linear equations

\[ Ax = b, \]  

where \( A \) is a sparse symmetric positive-definite matrix, following
the incomplete Cholesky factorization by F01MAF, given by

\[ T \]
\[ C = PDLDL P , \quad WAW = C + E, \]

where \( P \) is a permutation matrix, \( L \) is a unit lower triangular
matrix, \( D \) is a diagonal matrix with positive diagonal elements, \( E \)
is an error matrix representing elements dropped during the
factorization and diagonal elements that have been modified to
ensure that \( C \) is positive-definite, and \( W \) is a diagonal matrix,
chosen to make the diagonal elements of $WAW$ unity.

Equation (1) is solved by applying a pre-conditioned conjugate gradient method to the equations

$$-1 \quad (WAW)(Wx) = Wb, \quad (2)$$

using $C$ as the pre-conditioning matrix. Details of the conjugate gradient method are given in Munksgaard [1].

The iterative procedure is terminated if

$$||Wr|| <= (\eta), \quad (3)$$

where $r$ is the residual vector $r = b - Ax$, $||r||$ denotes the Euclidean length of $r$, $(\eta)$ is a user-supplied tolerance and $x$ is the current approximation to the solution. Notice that

$$-1 \quad Wr = Wb - (WAW)(Wx)$$

so that $Wr$ is the residual of the normalised equations (2).

F04MAF is based on the Harwell Library routine MA31B.

5. Parameters

1: N -- INTEGER Input  
   On entry: $n$, the order of the matrix $A$. Constraint: $N >= 1$.

2: NZ -- INTEGER Input  
   On entry: the number of non-zero elements in the upper triangular part of the matrix $A$, including the number of elements on the leading diagonal. Constraint: $NZ >= N$.

3: A(LICN) -- DOUBLE PRECISION array Input  
   On entry: the first $LROW$ elements, where $LROW$ is the value supplied in INFORM(1), must contain details of the factorization, as returned by F01MAF.

4: LICN -- INTEGER Input  
   On entry:
On entry: the length of the array A, as declared in the (sub)program from which F04MAF is called. It need never be larger than the value of LICN supplied to F01MAF.
Constraint: LICN >= INFORM(1).

5: IRN(LIRN) -- INTEGER array Input
On entry: the first LCDL elements, where LCDL is the value supplied in INFORM(2), must contain details of the factorization, as returned by F01MAF.

6: LIRN -- INTEGER Input
On entry: the length of the array IRN, as declared in the (sub)program from which F04MAF is called. It need never be larger than the value of LIRN supplied to F01MAF.
Constraint: LIRN >= INFORM(2).

7: ICN(LICN) -- INTEGER array Input
On entry: the first LROW elements, where LROW is the value supplied in INFORM(1), must contain details of the factorization, as returned by F01MAF.

8: B(N) -- DOUBLE PRECISION array Input/Output
On entry: the right-hand side vector b. On exit: B is overwritten by the solution vector x.

9: ACC(2) -- DOUBLE PRECISION array Input/Output
On entry: ACC(1) specifies the tolerance for convergence, (eta), in equation (3) of Section 3. If ACC(1) is outside the range [(epsilon),1], where (epsilon) is the machine precision, then the value (epsilon) is used in place of ACC(1). ACC(2) need not be set. On exit: ACC(2) contains the actual value of ||Wr|| at the final point. ACC(1) is unchanged.

10: NOITS(2) -- INTEGER array Input/Output
On entry: NOITS(1) specifies the maximum permitted number of iterations. If NOITS(1) < 1, then the value 100 is used in its place. NOITS(2) need not be set. On exit: NOITS(2) contains the number of iterations taken to converge. NOITS(1) is unchanged.

11: WKEEP(3*N) -- DOUBLE PRECISION array Input
On entry: WKEEP must be unchanged from the previous call of F01MAF.

12: WORK(3*N) -- DOUBLE PRECISION array Output
On exit: WORK(1) contains a lower bound for the condition number of A. The rest of the array is used for workspace.
13: IKEEP(2*N) -- INTEGER array Input
On entry: IKEEP must be unchanged from the previous call of F01MAF.

14: INFORM(4) -- INTEGER array Input
On entry: INFORM must be unchanged from the previous call of F01MAF.

15: IFAIL -- INTEGER Input/Output
For this routine, the normal use of IFAIL is extended to control the printing of error and warning messages as well as specifying hard or soft failure (see the Essential Introduction).

Before entry, IFAIL must be set to a value with the decimal expansion cba, where each of the decimal digits c, b and a must have a value of 0 or 1.
a=0 specifies hard failure, otherwise soft failure;
b=0 suppresses error messages, otherwise error messages will be printed (see Section 6);
c=0 suppresses warning messages, otherwise warning messages will be printed (see Section 6).
The recommended value for inexperienced users is 110 (i.e., hard failure with all messages printed).

Unless the routine detects an error (see Section 6), IFAIL contains 0 on exit.

6. Error Indicators and Warnings

Errors detected by the routine:

For each error, an explanatory error message is output on the current error message unit (as defined by X04AAF), unless suppressed by the value of IFAIL on entry.

IFAIL= 1
On entry N < 1,
or NZ < N,
or LICN < INFORM(1),
or LIRN < INFORM(2).

IFAIL= 2
Convergence has not taken place within the requested NOITS (1) number of iterations. ACC(2) gives the value ||Wr||,
for the final point. Either too few iterations have been allowed, or the requested convergence criterion cannot be met.

\[
\text{IFAIL}= 3
\]
The matrix \(A\) is singular, or nearly singular. Singularity has been detected during the conjugate gradient iterations, so that the computations are not complete.

\[
\text{IFAIL}= 4
\]
The matrix \(A\) is singular, or nearly singular. The message output on the current error message channel will include an estimate of the condition number of \(A\). In the case of soft failure an approximate solution is returned such that the value \(||W_r||\) is given by \(\text{ACC}(2)\) and the estimate (a lower bound) of the condition number is returned in \(\text{WORK}(1)\).
The n by n matrix $A$ arises in the solution of Laplace's equation in a unit-square, using a five-point formula with a 6 by 6 discretisation, with unity on the boundaries.

The drop tolerance, DROPTL, is taken as 0.1 and the density factor, DENSW, is taken as 0.8. The value IFAIL = 111 is used so that advisory and error messages will be printed, but soft failure would occur if IFAIL were returned as non-zero.

A relative accuracy of about 0.0001 is requested in the solution from F04MAF, with a maximum of 50 iterations.

The example program for F02FJF illustrates the use of routines F01MAF and F04MAF in solving an eigenvalue problem.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
Solves a system of real sparse symmetric linear equations

F04MBF(3NAG) Foundation Library (12/10/92) F04MBF(3NAG)

F04 -- Simultaneous Linear Equations
F04MBF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F04MBF solves a system of real sparse symmetric linear equations using a Lanczos algorithm.

2. Specification

SUBROUTINE F04MBF (N, B, X, APROD, MSOLVE, PRECON, SHIFT,
1 RTOL, ITNLIM, MSGLVL, ITN, ANORM,
2 ACOND, RNORM, XNORM, WORK, RWORK,
3 LAWORK, IWORK, LIWORK, INFORM, IFAIL)

INTEGER N, ITNLIM, MSGLVL, ITN, LRWORK, IWORK
DOUBLE PRECISION B(N), X(N), SHIFT, RTOL, ANORM, ACOND,
1 RNORM, XNORM, WORK(N,5), RWORK(LRWORK)
LOGICAL PRECON
EXTERNAL APROD, MSOLVE

3. Description

F04MBF solves the system of linear equations

\[(A-(\lambda)I)x=b\]  \hspace{1cm} (3.1)

where \(A\) is an \(n\) by \(n\) sparse symmetric matrix and \((\lambda)\) is a scalar, which is of course zero if the solution of the equations
Ax=b

is required. It should be noted that neither A nor (A-(lamba)I) need be positive-definite.

(lamba) is supplied as the parameter SHIFT, and allows F04MBF to be used for finding eigenvectors of A in methods such as Rayleigh quotient iteration (see for example Lewis [1]), in which case (lamba) will be an approximation to an eigenvalue of A and b an approximation to an eigenvector of A.

The routine also provides an option to allow pre-conditioning and this will often reduce the number of iterations required by F04MBF.

F04MBF is based upon algorithm SYMMLQ (see Paige and Saunders [2]) and solves the equations by an algorithm based upon the Lanczos process. Details of the method are given in Paige and Saunders [2]. The routine does not require A explicitly, but A is specified via a user-supplied routine APROD which, given an n element vector c, must return the vector z given by

\[ z = Ac. \]

The pre-conditioning option is based on the following reasoning. If A can be expressed in the form

\[ A = I + B \]

where B is of rank (rho), then the Lanczos process converges (in exact arithmetic) in at most (rho) iterations. If more generally A can be expressed in the form

\[ A = M + C \]

where M is symmetric positive-definite and C has rank (rho), then

\[
\begin{bmatrix}
-(1/2) & -(1/2) & -(1/2) & -(1/2)
\end{bmatrix}
\begin{bmatrix}
M & AM & =I+M & CM
\end{bmatrix}
\]

\[-(1/2) -(1/2)\]

and M AM also has rank (rho), and the Lanczos process applied to M AM would again converge in at most (rho) iterations. On a computer, the number of iterations may be greater than (rho), but the Lanczos process may still be expected to converge rapidly. F04MBF does not require M AM to be formed explicitly, but implicitly solves the equations
with the user being required to supply a routine MSOLVE to solve the equations

\[ Mz = c. \quad (3.3) \]

For the pre-conditioning option to be effective, it is desirable that equations (3.3) can be solved efficiently. The example program in Section 9 illustrates the use of this option.

If we let \( r \) denote the residual vector

\[ r = b - (A - \lambda I)x \]

corresponding to an iterate \( x \), then, when pre-conditioning has not been requested, the iterative procedure is terminated if it is estimated that

\[ ||r|| \leq \text{tol}.||A - \lambda I||.||x||, \quad (3.4) \]

where \( \text{tol} \) is a user-supplied tolerance, \( ||r|| \) denotes the Euclidean length of the vector \( r \) and \( ||A|| \) denotes the Frobenius (Euclidean) norm of the matrix \( A \). When pre-conditioning has been requested, the iterative procedure is terminated if it is estimated that

\[ \frac{1}{2} \quad \frac{1}{2} \quad \frac{1}{2} \quad \frac{1}{2} \]

\[ ||M r|| \leq \text{tol}.||M (A - \lambda I)M ||.||M x||. \quad (3.5) \]

Note that

\[ \frac{1}{2} \quad \frac{1}{2} \quad \frac{1}{2} \quad \frac{1}{2} \]

\[ ||M r|| \leq \text{tol}.||M (A - \lambda I)M ||.||M x||. \quad (3.5) \]

so that \( M \) \( r \) is the residual vector corresponding to equation (3.2). The routine will also terminate if it is estimated that

\[ \frac{1}{2} \quad \frac{1}{2} \quad \frac{1}{2} \quad \frac{1}{2} \]

\[ ||A - \lambda I||.||x|| > ||b||/(\epsilon), \quad (3.6) \]

where \( \epsilon \) is the machine precision, when pre-conditioning has not been requested; or if it is estimated that

\[ \frac{1}{2} \quad \frac{1}{2} \quad \frac{1}{2} \quad \frac{1}{2} \]

\[ ||M (A - \lambda I)M ||.||M x|| > ||M b||/(\epsilon) \]
when pre-conditioning has been requested. If (3.6) is satisfied then \( x \) is almost certainly an eigenvector of \( A \) corresponding to the eigenvalue \( \lambda \). If \( \lambda \) was set to 0 (for the solution of \( Ax=b \)), then this condition simply means that \( A \) is effectively singular.

4. References

5. Parameters

1: \( N \) -- INTEGER Input
On entry: \( n \), the order of the matrix \( A \). Constraint: \( N \geq 1 \).

2: \( B(N) \) -- DOUBLE PRECISION array Input
On entry: the right-hand side vector \( b \).

3: \( X(N) \) -- DOUBLE PRECISION array Output
On exit: the solution vector \( x \).

4: \( APROD \) -- SUBROUTINE, supplied by the user.
External Procedure
APROD must return the vector \( y=Ax \) for a given vector \( x \).

Its specification is:

```
SUBROUTINE APROD (IFLAG, N, X, Y, RWORK, LRWORK, 1
                 INTEGER IFLAG, N, LRWORK, LIWORK, IWORK
                 DOUBLE PRECISION X(N), Y(N), RWORK(LRWORK)
```

1: \( IFLAG \) -- INTEGER Input/Output
On entry: \( IFLAG \) is always non-negative. On exit: \( IFLAG \) may be used as a flag to indicate a failure in the computation of \( Ax \). If \( IFLAG \) is negative on exit from APROC, F04MBF will exit immediately with IFAIL set to IFLAG.

2: \( N \) -- INTEGER Input
On entry: \( n \), the order of the matrix \( A \).
3: \( X(N) \) -- DOUBLE PRECISION array 
   Input 
   On entry: the vector \( x \) for which \( Ax \) is required.

4: \( Y(N) \) -- DOUBLE PRECISION array 
   Output 
   On exit: the vector \( y=Ax \).

5: \( RWORK(LRWORK) \) -- DOUBLE PRECISION array 
   User Workspace

6: \( LRWORK \) -- INTEGER 
   Input

7: \( IWORK(LIWORK) \) -- INTEGER array 
   User Workspace

8: \( LIWORK \) -- INTEGER 
   Input

APROD is called from F04MBF with the parameters \( RWORK \), \( LRWORK \), \( IWORK \) and \( LIWORK \) as supplied to F04MBF. The user is free to use the arrays \( RWORK \) and \( IWORK \) to supply information to APROD and MSOLVE as an alternative to using COMMON.

APROD must be declared as EXTERNAL in the (sub)program from which F04MBF is called. Parameters denoted as Input must not be changed by this procedure.

5: MSOLVE -- SUBROUTINE, supplied by the user.

MSOLVE is only referenced when PRECON is supplied as .TRUE.. When PRECON is supplied as .FALSE., then F04MBF may be called with APROD as the actual argument for MSOLVE. When PRECON is supplied as .TRUE., then MSOLVE must return the solution \( y \) of the equations \( My=x \) for a given vector \( x \), where \( M \) must be symmetric positive-definite.

Its specification is:

\[
\text{SUBROUTINE MSOLVE (IFLAG, N, X, Y, RWORK, LRWORK, IWORK, LIWORK)}
\]

1: \( IFLAG \) -- INTEGER 
   Input/Output 
   On entry: IFLAG is always non-negative. On exit: IFLAG may be used as a flag to indicate a failure in the solution of \( My=x \).

   If IFLAG is negative on exit from MSOLVE, F04MBF will exit immediately with IFAIL set to IFLAG.

2: \( N \) -- INTEGER 
   Input 
   On entry: \( n \), the order of the matrix \( M \).
3: \textit{X(N)} -- DOUBLE PRECISION array Input
   On entry: the vector \textit{x} for which the equations \textit{My}=\textit{x} are to be solved.

4: \textit{Y(N)} -- DOUBLE PRECISION array Output
   On exit: the solution to the equations \textit{My}=\textit{x}.

5: \textit{RWORK(LRWORK)} -- DOUBLE PRECISION array User Workspace

6: \textit{LRWORK} -- INTEGER Input

7: \textit{IWORK(LIWORK)} -- INTEGER array User Workspace

8: \textit{LIWORK} -- INTEGER Input
   \textit{MSOLVE} is called from \textit{F04MBF} with the parameters \textit{RWORK}, \textit{LRWORK}, \textit{IWORK} and \textit{LIWORK} as supplied to \textit{F04MBF}. The user is free to use the arrays \textit{RWORK} and \textit{IWORK} to supply information to \textit{APROD} and \textit{MSOLVE} as an alternative to using COMMON. \textit{MSOLVE} must be declared as EXTERNAL in the (sub)program from which \textit{F04MBF} is called. Parameters denoted as Input must not be changed by this procedure.

6: \textit{PRECON} -- LOGICAL Input
   On entry: \textit{PRECON} specifies whether or not pre-conditioning is required. If \textit{PRECON} = .TRUE., then pre-conditioning will be invoked and \textit{MSOLVE} will be referenced by \textit{F04MBF}; if \textit{PRECON} = .FALSE., then \textit{MSOLVE} is not referenced.

7: \textit{SHIFT} -- DOUBLE PRECISION Input
   On entry: the value of (\textit{lambda}). If the equations \textit{Ax}=\textit{b} are to be solved, then \textit{SHIFT} must be supplied as zero.

8: \textit{RTOL} -- DOUBLE PRECISION Input
   On entry: the tolerance for convergence, \textit{tol}, of equation (3.4). \textit{RTOL} should not normally be less than (\textit{epsilon}), where (\textit{epsilon}) is the machine precision.

9: \textit{ITNLIM} -- INTEGER Input
   On entry: an upper limit on the number of iterations. If \textit{ITNLIM} <= 0, then the value \textit{N} is used in place of \textit{ITNLIM}.

10: \textit{MSGLVL} -- INTEGER Input
    On entry: the level of printing from \textit{F04MBF}. If \textit{MSGLVL} <= 0, then no printing occurs, but otherwise messages will be output on the advisory message channel (see \textit{X04ABF}). A description of the printed output is given in Section 5.1 below. The level of printing is determined as follows: \textit{MSGLVL} <= 0
No printing.

**MSGLVL = 1**
A brief summary is printed just prior to return from F04MBF.

**MSGLVL >= 2**
A summary line is printed periodically to monitor the progress of F04MBF, together with a brief summary just prior to return from F04MBF.

11: ITN -- INTEGER Output
On exit: the number of iterations performed.

12: ANORM -- DOUBLE PRECISION Output
On exit: an estimate of $||A-(\lambda)I||$ when PRECON = -(1/2) -(1/2)
FALSE, and $||M (A-(\lambda)I)M ||$ when PRECON = .TRUE.

13: ACOND -- DOUBLE PRECISION Output
On exit: an estimate of the condition number of $A-(\lambda)I$ when PRECON = .FALSE., and of $-(1/2) -(1/2)$ $M (A-(\lambda)I)M$ when PRECON = .TRUE.. This will usually be a substantial under-estimate.

14: RNORM -- DOUBLE PRECISION Output
On exit: $||r||$, where $r=b-(A-(\lambda)I)x$ and $x$ is the solution returned in X.

15: XNORM -- DOUBLE PRECISION Output
On exit: $||x||$, where $x$ is the solution returned in X.

16: WORK(5*N) -- DOUBLE PRECISION array Workspace

17: RWORK(LRWORK) -- DOUBLE PRECISION array User Workspace
RWORK is not used by F04MBF, but is passed directly to routines APROD and MSOLVE and may be used to pass information to these routines.

18: LRWORK -- INTEGER Input
On entry: the length of the array RWORK as declared in the (sub)program from which F04MBF is called. Constraint: LRWORK >= 1.

19: IWORK(LIWORK) -- INTEGER array User Workspace
IWORK is not used by F04MBF, but is passed directly to routines APROD and MSOLVE and may be used to pass information to these routines.
CHAPTER 22. NAG LIBRARY ROUTINES

20: LIWORK -- INTEGER  Input
On entry: the length of the array LIWORK as declared in the
(sub)program from which F04MBF is called. Constraint: LIWORK
>= 1.

21: INFORM -- INTEGER  Output
On exit: the reason for termination of F04MBF as follows:
INFORM = 0
The right-hand side vector b=0 so that the exact
solution is x=0. No iterations are performed in this
case.

INFORM = 1
The termination criterion of equation (3.4) has been
satisfied with tol as the value supplied in RTOL.

INFORM = 2
The termination criterion of equation (3.4) has been
satisfied with tol equal to (eps), where (eps) is the machine precision. The value supplied in RTOL
must have been less than (eps) and was too small
for the machine.

INFORM = 3
The termination criterion of equation (3.5) has been
satisfied so that X is almost certainly an eigenvector
of A corresponding to the eigenvalue SHIFT.
The values INFORM = 4 and INFORM = 5 correspond to failure
with IFAIL = 3 or IFAIL = 2 respectively (see Section 6) and
when IFAIL is negative, INFORM will be set to the same
negative value.

22: IFAIL -- INTEGER  Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not
familiar with this parameter (described in the Essential
Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see
Section 6).

5.1. Description of the Printed Output

When MSGVL > 0, then F04MBF will produce output (except in the
case where the routine fails with IFAIL = 1) on the advisory
message channel (see X04ABF).

The following notation is used in the output.

Output  Meaning
\[(b-(A-(\lambda)I)x)=r\]
\[(A-(\lambda)I)M = A^{1/2}\]
\[b-(A-(\lambda)I)x\]
\[NORM(A) \|A\|\]

Of course, when pre-conditioning has not been requested then the first three reduce to \((b-(A-(\lambda)I)x)\), \((A-(\lambda)I)\) and \(x\) respectively. When MSGVL >= 2 then some initial information is printed and the following notation is used.

<table>
<thead>
<tr>
<th>Output</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>ITN</td>
<td>Iteration number, (k).</td>
</tr>
<tr>
<td>L1(LQ)</td>
<td>The first element of the vector (x), where (x) is the current iterate. See Paige and Saunders [2] for details.</td>
</tr>
<tr>
<td>L1(CG)</td>
<td>The first element of the vector (x), where (x) is the vector that would be obtained by conjugate gradients. See Paige and Saunders [2] for details.</td>
</tr>
</tbody>
</table>
CHAPTER 22. NAG LIBRARY ROUTINES

NORM(RBAR) \[||r||\], where \(r\) is as defined above and \(x\) is either
\[
\begin{align*}
L & \quad \text{C} \\
\text{x} & \quad \text{or} \quad \text{x} \quad \text{depending upon which is the best current} \\
\text{k} & \quad \text{k} \\
\text{approximation to the solution. (See LQ/CG below).}
\end{align*}
\]

NORM(T) The value \[||T||\], where \(T\) is the tridiagonal
\[
\begin{align*}
k & \quad k \\
\text{matrix of the Lanczos process. This increases}
\end{align*}
\]
monotonically and is a lower bound on \[||A||\].

COND(L) A monotonically increasing lower bound on the
\[\text{condition number of} \, A, \, \|A\| \|A^{-1}\|\].

L

LQ/CG L is printed if \(x\) is the best current
\[
k \\
\text{k}
\]
approximation to the solution and C is printed otherwise.

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL< 0
A negative value of IFAIL indicates an exit from F04MBF
because the user has set IFLAG negative in APROD or MSOLVE. The value of IFAIL will be the same as the user’s setting of IFLAG.

IFAIL= 1
On entry \(N < 1\),
or \(LRWORK < 1\),
or \(LIWORK < 1\).

IFAIL= 2
The pre-conditioning matrix \(M\) does not appear to be positive-definite. The user should check that MSOLVE is working correctly.

IFAIL= 3
The limit on the number of iterations has been reached. If IFAIL = 1 on entry then the latest approximation to the solution is returned in \(X\) and the values ANORM, ACOND, RNORM
and XNORM are also returned.

The value of INFORM contains additional information about the termination of the routine and users must examine INFORM to judge whether the routine has performed successfully for the problem in hand. In particular INFORM = 3 denotes that the matrix A-(\lambda)I is effectively singular: if the purpose of calling F04MBF is to solve a system of equations Ax=b, then this condition must be regarded as a failure, but if the purpose is to compute an eigenvector, this result would be very satisfactory.

7. Accuracy

The computed solution x will satisfy the equation

\[ r = b - (A-(\lambda)I)x \]

where the value ||r|| is as returned in the parameter RNORM.

8. Further Comments

The time taken by the routine is likely to be principally determined by the time taken in APROD and, when pre-conditioning has been requested, in MSOLVE. Each of these routines is called once every iteration.

The time taken by the remaining operations in F04MBF is approximately proportional to n.

9. Example

To solve the 10 equations Ax=b given by

\[
\begin{pmatrix}
2 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 3 \\
1 & 2 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 1 & 2 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 2 & 1 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 2 & 1 & 0 & 0 & 0 & 0
\end{pmatrix}
\begin{pmatrix}
6 \\
4 \\
4 \\
4 \\
4 \\
6 \\
6 \\
6 \\
6 \\
6
\end{pmatrix}
\begin{pmatrix}
A=(0 & 0 & 0 & 1 & 2 & 1 & 0 & 0 & 0, \\
0 & 0 & 0 & 0 & 1 & 2 & 1 & 0 & 0, \\
0 & 0 & 0 & 0 & 0 & 1 & 2 & 1 & 0, \\
0 & 0 & 0 & 0 & 0 & 0 & 1 & 2 & 1, \\
3 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 2)
\end{pmatrix}
\begin{pmatrix}
b=(4). \\
4 \\
4 \\
4 \\
4 \\
4 \\
4 \\
4 \\
4 \\
4
\end{pmatrix}
\]

The tridiagonal part of A is positive-definite and such tridiagonal equations can be solved efficiently by F04FAF. The form of A suggests that this tridiagonal part is a good candidate for the pre-conditioning matrix M and so we illustrate the use of F04MBF by pre-conditioning with the 10 by 10 matrix
Since \( A-M \) has only 2 non-zero elements and is obviously of rank 2, we can expect F04MBF to converge very quickly in this example. Of course, in practical problems we shall not usually be able to make such a good choice of \( M \).

The example sets the tolerance RTOL = 10.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

Solution of a system of real linear equations

\[ \begin{pmatrix} 2 & 1 & 0 & \cdots & 0 \\ 1 & 2 & 1 & \cdots & 0 \\ 0 & 1 & 2 & \cdots & 0 \end{pmatrix} \]
\[ M = (\cdots \cdots) \]
not included in the Foundation Library.

1. Purpose

F04MCF computes the approximate solution of a system of real linear equations with multiple right-hand sides, $AX=B$, where $A$ is a symmetric positive-definite variable-bandwidth matrix, which has previously been factorized by F01MCF. Related systems may also be solved.

2. Specification

```
SUBROUTINE F04MCF (N, AL, LAL, D, NROW, IR, B, NRB, 1
  ISELCT, X, NRX, IFAIL)
  INTEGER N, LAL, NROW(N), IR, NRB, ISELCT, NRX, 1
  IFAIL
  DOUBLE PRECISION AL(LAL), D(N), B(NRB,IR), X(NRX,IR)
```

3. Description

The normal use of this routine is the solution of the systems $AX=B$, following a call of F01MCF to determine the Cholesky $T$ factorization $A=LDL$ of the symmetric positive-definite variable-bandwidth matrix $A$.

However, the routine may be used to solve any one of the following systems of linear algebraic equations:

T
(1) $LDL X = B$ (usual system),
(2) $LDX = B$ (lower triangular system),
T
(3) $DLX = B$ (upper triangular system),
T
(4) $LLX = B$
(5) $LX = B$ (unit lower triangular system),
T
(6) $LX = B$ (unit upper triangular system).

$L$ denotes a unit lower triangular variable-bandwidth matrix of order $n$, $D$ a diagonal matrix of order $n$, and $B$ a set of right-hand sides.

The matrix $L$ is represented by the elements lying within its
envelope i.e., between the first non-zero of each row and the
diagonal (see Section 9 for an example). The width NROW(i) of the
ith row is the number of elements between the first non-zero
element and the element on the diagonal inclusive.

4. References

5. Parameters

1: N -- INTEGER Input
   On entry: n, the order of the matrix L. Constraint: N >= 1.

2: AL(LAL) -- DOUBLE PRECISION array Input
   On entry: the elements within the envelope of the lower
   triangular matrix L, taken in row by row order, as returned
   by F01MCF. The unit diagonal elements of L must be stored
   explicitly.

3: LAL -- INTEGER Input
   On entry:
   the dimension of the array AL as declared in the
   (sub)program from which F04MCF is called.
   Constraint: LAL >= NROW(1) + NROW(2) +... + NROW(n).

4: D(N) -- DOUBLE PRECISION array Input
   On entry: the diagonal elements of the diagonal matrix D. D
   is not referenced if ISELCT >= 4.

5: NROW(N) -- INTEGER array Input
   On entry: NROW(i) must contain the width of row i of L,
   i.e., the number of elements between the first (leftmost)
   non-zero element and the element on the diagonal, inclusive.
   Constraint: 1 <= NROW(i)<=i.

6: IR -- INTEGER Input
   On entry: r, the number of right-hand sides. Constraint: IR
   >= 1.

7: B(NRB,IR) -- DOUBLE PRECISION array Input
   On entry: the n by r right-hand side matrix B. See also
   Section 8.

8: NRB -- INTEGER Input
   On entry:
   the first dimension of the array B as declared in the
   (sub)program from which F04MCF is called.
   Constraint: NRB >= N.
9: ISELCT -- INTEGER
Input
On entry: ISELCT must specify the type of system to be solved, as follows:

\[
\begin{align*}
T & \\
\text{ISELCT} = 1: & \text{solve } LDL \cdot X = B, \\
\text{ISELCT} = 2: & \text{solve } LDX = B, \\
\text{T} & \\
\text{ISELCT} = 3: & \text{solve } DL \cdot X = B, \\
\text{T} & \\
\text{ISELCT} = 4: & \text{solve } LL \cdot X = B, \\
\text{T} & \\
\text{ISELCT} = 5: & \text{solve } LX = B, \\
\text{T} & \\
\text{ISELCT} = 6: & \text{solve } L \cdot X = B.
\end{align*}
\]

10: X(NRX,IR) -- DOUBLE PRECISION array
Output
On exit: the \( n \) by \( r \) solution matrix \( X \). See also Section 8.

11: NRX -- INTEGER
Input
On entry:
the first dimension of the array \( X \) as declared in the (sub)program from which F04MCF is called.
Constraint: \( NRX \geq N \).

12: IFAIL -- INTEGER
Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL = 1
On entry \( N < 1 \),
or for some \( i \), \( \text{NRW}(i) < 1 \) or \( \text{NRW}(i) > i \),
or \( \text{LAL} < \text{NRW}(1) + \text{NRW}(2) + \ldots + \text{NRW}(N) \).

IFAIL = 2
On entry IR < 1, 
or NRB < N, 
or NRX < N.

IFAIL= 3
On entry ISELCT < 1, 
or ISELCT > 6.

IFAIL= 4
The diagonal matrix D is singular, i.e., at least one of the elements of D is zero. This can only occur if ISELCT <= 3.

IFAIL= 5
At least one of the diagonal elements of L is not equal to unity.

7. Accuracy

The usual backward error analysis of the solution of triangular system applies: each computed solution vector is exact for slightly perturbed matrices L and D, as appropriate (cf. Wilkinson and Reinsch [1] pp 25--27, 54--55).

8. Further Comments

The time taken by the routine is approximately proportional to 
pr, where

\[ p = NROW(1) + NROW(2) + \ldots + NROW(n). \]

Unless otherwise stated in the Users' Note for your implementation, the routine may be called with the same actual array supplied for the parameters B and X, in which case the solution matrix will overwrite the right-hand side matrix. However this is not standard Fortran 77 and may not work in all implementations.

9. Example

To solve the system of equations AX=B, where

\[
\begin{pmatrix}
1 & 2 & 0 & 0 & 5 & 0 \\
2 & 5 & 3 & 0 & 14 & 0 \\
0 & 3 & 13 & 0 & 18 & 0 \\
5 & 14 & 18 & 8 & 24 & 0 \\
0 & 0 & 0 & 16 & 8 & 24 \\
0 & 0 & 18 & 8 & 55 & 17
\end{pmatrix}
\]
Here $A$ is symmetric and positive-definite and must first be factorized by F01MCF.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

Solves sparse unsymmetric equations

— nagf.ht —
F04QAF solves sparse unsymmetric equations, sparse linear least-squares problems and sparse damped linear least-squares problems, using a Lanczos algorithm.

2. Specification

SUBROUTINE F04QAF (M, N, B, X, SE, APROD, DAMP, ATOL,
1          BTOL, CONLIM, ITNLIM, MSGGLVL, ITN,
2          ANORM, ACOND, RNORM, ARNORM, XNORM,
3          WORK, RWORK, LRWORK, IWORk, LIWORK,
4          INFORM, IFAIL)

INTEGER M, N, ITNLIM, MSGGLVL, ITN, LRWORK, IWORk, LIWORK
1          (LIWORK), LIWORK, INFORM, IFAIL
DOUBLE PRECISION B(M), X(N), SE(N), DAMP, ATOL, BTOL,
1          CONLIM, ANORM, ACOND, RNORM, ARNORM,
2          XNORM, WORK(N,2), RWORK(LRWORK)
EXTERNAL APROD

3. Description

F04QAF can be used to solve a system of linear equations

\[ Ax = b \]  \hspace{1cm} (3.1)

where \( A \) is an \( n \) by \( n \) sparse unsymmetric matrix, or can be used to solve linear least-squares problems, so that F04QAF minimizes the value (\( \rho \)) given by

\[ \rho = ||r||, \quad r = b - Ax \]  \hspace{1cm} (3.2)

where \( A \) is an \( m \) by \( n \) sparse matrix and \( ||r|| \) denotes the Euclidean length of \( r \) so that \( ||r|| = r^T r \). A damping parameter, \( \lambda \), may be included in the least-squares problem in which case F04QAF minimizes the value (\( \rho \)) given by

\[ \rho = ||r||^2 + (\lambda) ||x||^2 \]  \hspace{1cm} (3.3)

(\( \lambda \)) is supplied as the parameter DAMP and should of course be zero if the solution to problems (3.1) or (3.2) is required. Minimizing (\( \rho \)) in (3.3) is often called ridge regression.

F04QAF is based upon algorithm LSQR (see Paige and Saunders [1] and [2]) and solves the problems by an algorithm based upon the Lanczos process. Details of the method are given in [1]. The routine does not require \( A \) explicitly, but \( A \) is specified via a user-supplied routine APROD which must perform the operations (\( A^T \))
y+Ax) and (x+A y) for a given n element vector x and m element vector y. A parameter to APROD specifies which of the two operations is required on a given entry.

The routine also returns estimates of the standard errors of the sample regression coefficients \( x_i \), for \( i=1,2,\ldots,n \) given by the diagonal elements of the estimated variance-covariance matrix V. When problem (3.2) is being solved and A is of full rank, then V is given by

\[
V = s (A^T A)^{-1}, \quad s = \frac{\rho}{m-n}, \quad m>n
\]

and when problem (3.3) is being solved then V is given by

\[
V = s (A^T A + \lambda I)^{-1}, \quad s = \frac{\rho}{m}, \quad \lambda \neq 0.
\]

Let A denote the matrix

\[
A = A, \quad \lambda = 0 ; \quad A = (\lambda I), \quad \lambda \neq 0,
\]

let r denote the residual vector

\[
r = r, \quad \lambda = 0 ; \quad r = (0) - Ax, \quad \lambda \neq 0
\]

corresponding to an iterate x, so that \( (\rho) = ||r|| \) is the function being minimized, and let \( ||A|| \) denote the Frobenius (Euclidean) norm of A. Then the routine accepts x as a solution if it is estimated that one of the following two conditions is satisfied:

\[
\begin{align*}
\rho & \leq tol \, ||A|| \, ||x|| + tol \, ||b|| \\
||A r|| & \leq tol \, ||A|| (\rho)
\end{align*}
\]
where tol and tol are user-supplied tolerances which estimate the relative errors in A and b respectively. Condition (3.6) is appropriate for compatible problems where, in theory, we expect the residual to be zero and will be satisfied by an acceptable solution x to a compatible problem. Condition (3.7) is appropriate for incompatible systems where we do not expect the residual to be zero and is based upon the observation that, in theory,

\[ T \]
\[ A^T r = 0 \]

when x is a solution to the least-squares problem, and so (3.7) will be satisfied by an acceptable solution x to a linear least-squares problem.

The routine also includes a test to prevent convergence to solutions, x, with unacceptably large elements. This can happen if A is nearly singular or is nearly rank deficient. If we let the singular values of A be

\[ \sigma_1 \geq \sigma_2 \geq \ldots \geq \sigma_n \geq 0 \]

then the condition number of A is defined as

\[ \text{cond}(A) = \frac{\sigma_n}{\sigma_k} \]

where (\sigma_k) is the smallest non-zero singular value of A and k hence k is the rank of A. When k<n, then A is rank deficient, the least-squares solution is not unique and F04QAF will normally converge to the minimal length solution. In practice A will not have exactly zero singular values, but may instead have small singular values that we wish to regard as zero.
The routine provides for this possibility by terminating if

\[ \text{cond}(A) \geq c \]

where \( c \) is a user-supplied limit on the condition number of \( A \).

For problem (3.1) termination with this condition indicates that \( A \) is nearly singular and for problem (3.2) indicates that \( A \) is nearly rank deficient and so has near linear dependencies in its columns. In this case inspection of \( \|r\|, \|A\| \) and \( \|x\| \), which are all returned by the routine, will indicate whether or not an acceptable solution has been found. Condition (3.8), perhaps in conjunction with \((\text{lambda})=0\), can be used to try and 'regularise' least-squares solutions. A full discussion of the stopping criteria is given in Section 6 of reference Paige and Saunders [1].

Introduction of a non-zero damping parameter \( (\text{lambda}) \) tends to reduce the size of the computed solution and to make its components less sensitive to changes in the data, and F04QAF is applicable when a value of \( (\text{lambda}) \) is known a priori. To have an effect, \( (\text{lambda}) \) should normally be at least \( \sqrt{\text{epsilon}} \|A\| \) where \( \text{epsilon} \) is the machine precision. For further discussion see Paige and Saunders [2] and the references given there.

Whenever possible the matrix \( A \) should be scaled so that the relative errors in the elements of \( A \) are all of comparable size. Such a scaling helps to prevent the least-squares problem from being unnecessarily sensitive to data errors and will normally reduce the number of iterations required. At the very least, in the absence of better information, the columns of \( A \) should be scaled to have roughly equal column length.

4. References

5. Parameters

1: M -- INTEGER Input
   On entry: m, the number of rows of the matrix A.
   Constraint: M >= 1.

2: N -- INTEGER Input
   On entry: n, the number of columns of the matrix A.
   Constraint: N >= 1.

3: B(M) -- DOUBLE PRECISION array Input/Output
   On entry: the right-hand side vector b. On exit: the array
   is overwritten.

4: X(N) -- DOUBLE PRECISION array Output
   On exit: the solution vector x.

5: SE(N) -- DOUBLE PRECISION array Output
   On exit: the estimates of the standard errors of the
   components of x. Thus SE(i) contains an estimate of the
   element v of the estimated variance-covariance matrix V.
   The estimates returned in SE will be the lower bounds on the
   actual estimated standard errors, but will usually have at
   least one correct figure.

6: APROD -- SUBROUTINE, supplied by the user.
   External Procedure
   APROD must perform the operations y:=y+Ax and x:=x+A y for
   given vectors x and y.

   Its specification is:

   SUBROUTINE APROD (MODE, M, N, X, Y, RWORK,
   1 LRWORK, IWORK, LIWORK)
   INTEGER MODE, M, N, LRWORK, LIWORK,
   1 IWORK(LIWORK)
   DOUBLE PRECISION X(N), Y(M), RWORK(LRWORK)

   1: MODE -- INTEGER Input/Output
      On entry: MODE specifies which operation is to be
      performed:
      If MODE = 1, then APROD must compute y+Ax.
      If MODE = 2, then APROD must compute x+A y.
      On exit: MODE may be used as a flag to indicate a
failure in the computation of \( y + Ax \) or \( x + A y \). If MODE is negative on exit from APROD, F04QAF will exit immediately with IFAIL set to MODE.

2:  M -- INTEGER  
    On entry: m, the number of rows of A.

3:  N -- INTEGER  
    On entry: n, the number of columns of A.

4:  X(N) -- DOUBLE PRECISION array  
    On entry: the vector x. On exit: if MODE = 1, X must be unchanged;

\[ T \]

If MODE = 2, X must contain \( x + A y \).

5:  Y(M) -- DOUBLE PRECISION array  
    On entry: the vector y. On exit: if MODE = 1, Y must contain \( y + Ax \);

If MODE = 2, Y must be unchanged.

6:  RWORK(LRWORK) -- DOUBLE PRECISION array  
    User Workspace

7:  LRWORK -- INTEGER  

8:  IWORK(LIWORK) -- INTEGER array  
    User Workspace

9:  LIWORK -- INTEGER  
    APROD is called from F04QAF with the parameters RWORK, LRWORK, IWORK and LIWORK as supplied to F04QAF. The user is free to use the arrays RWORK and IWORK to supply information to APROD as an alternative to using COMMON. APROD must be declared as EXTERNAL in the (sub)program from which F04QAF is called. Parameters denoted as Input must not be changed by this procedure.

7:  DAMP -- DOUBLE PRECISION  
    On entry: the value (\( \lambda \)). If either problem (3.1) or problem (3.2) is to be solved, then DAMP must be supplied as zero.

8:  ATOL -- DOUBLE PRECISION  
    On entry: the tolerance, \( \text{tol} \), of the convergence criteria \( (3.6) \) and \( (3.7) \); it should be an estimate of the largest relative error in the elements of A. For example, if the elements of A are correct to about 4 significant figures,
then ATOL should be set to about $5 \times 10^{-4}$. If ATOL is supplied as less than (epsilon), where (epsilon) is the machine precision, then the value (epsilon) is used in place of ATOL.

9: BTOL -- DOUBLE PRECISION
On entry: the tolerance, tol, of the convergence criterion

$\varepsilon$; it should be an estimate of the largest relative
error in the elements of B. For example, if the elements of
B are correct to about 4 significant figures, then BTOL
should be set to about $5 \times 10^{-4}$. If BTOL is supplied as less
than (epsilon), where (epsilon) is the machine precision,
then the value (epsilon) is used in place of BTOL.

10: CONLIM -- DOUBLE PRECISION
On entry: the value $c$ of equation (3.8); it should be an upper limit on the condition number of A. CONLIM should not normally be chosen much larger than $1.0/\text{ATOL}$. If CONLIM is supplied as zero then the value $1.0/(\text{epsilon})$, where (epsilon) is the machine precision, is used in place of CONLIM.

11: ITNLIM -- INTEGER
On entry: an upper limit on the number of iterations. If ITNLIM $\leq 0$, then the value N is used in place of ITNLIM, but for ill-conditioned problems a higher value of ITNLIM is likely to be necessary.

12: MSGLVL -- INTEGER
On entry: the level of printing from F04QAF. If MSGLVL $\leq 0$, then no printing occurs, but otherwise messages will be output on the advisory message channel (see X04ABF). A description of the printed output is given in Section 5.2 below. The level of printing is determined as follows:

MSGLVL $\leq 0$
No printing.

MSGLVL = 1
A brief summary is printed just prior to return from F04QAF.

MSGLVL $\geq 2$
A summary line is printed periodically to monitor the progress of F04QAF, together with a brief summary just
prior to return from F04QAF.

13: ITN -- INTEGER
   On exit: the number of iterations performed.

14: ANORM -- DOUBLE PRECISION
   On exit: an estimate of \( ||A|| \) for the matrix \( A \) of equation (3.4).

15: ACOND -- DOUBLE PRECISION
   On exit: an estimate of \( \text{cond}(A) \) which is a lower bound.

16: RNORM -- DOUBLE PRECISION
   On exit: an estimate of \( ||r|| \) for the residual, \( r \), of equation (3.5) corresponding to the solution \( x \) returned in \( X \). Note that \( ||r|| \) is the function being minimized.

17: ARNORM -- DOUBLE PRECISION
   On exit: an estimate of the \( ||A r|| \) corresponding to the solution \( x \) returned in \( X \).

18: XNORM -- DOUBLE PRECISION
   On exit: an estimate of \( ||x|| \) for the solution \( x \) returned in \( X \).

19: WORK(2*N) -- DOUBLE PRECISION array
   Workspace

20: RWORK(LRWORK) -- DOUBLE PRECISION array
   User Workspace
   RWORK is not used by F04QAF, but is passed directly to routine APROD and may be used to pass information to that routine.

21: LRWORK -- INTEGER
   On entry: the length of the array RWORK as declared in the (sub)program from which F04QAF is called. Constraint: LRWORK >= 1.

22: IWORK(LIWORK) -- INTEGER array
   User Workspace
   IWORK is not used by F04QAF, but is passed directly to routine APROD and may be used to pass information to that routine.
CHAPTER 22. NAG LIBRARY ROUTINES

23: LIWORK -- INTEGER
Input
On entry: the length of the array IWORK as declared in the
(sub)program from which F04QAF is called. Constraint: LIWORK
>= 1.

24: INFORM -- INTEGER
Output
On exit: the reason for termination of F04QAF as follows:
INFORM = 0
The exact solution is x=0. No iterations are performed
in this case.

INFORM = 1
The termination criterion of equation (3.6) has been
satisfied with tol and tol as the values supplied in
1 2
ATOL and BTOL respectively.

INFORM = 2
The termination criterion of equation (3.7) has been
satisfied with tol as the value supplied in ATOL.
1

INFORM = 3
The termination criterion of equation (3.6) has been
satisfied with tol and/or tol as the value (epsilon)
1 2
, where (epsilon) is the machine precision. One or
both of the values supplied in ATOL and BTOL must have
been less than (epsilon) and was too small for this
machine.

INFORM = 4
The termination criterion of equation (3.7) has been
satisfied with tol as the value (epsilon), where
1
(epsilon) is the machine precision. The value supplied
in ATOL must have been less than (epsilon) and was too
small for this machine.
The values INFORM = 5, INFORM = 6 and INFORM = 7 correspond
to failure with IFAIL = 2, IFAIL = 3 and IFAIL = 4
respectively (see Section 6) and when IFAIL is negative
INFORM will be set to the same negative value.

25: IFAIL -- INTEGER
Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not
familiar with this parameter (described in the Essential
Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see
5.1. Description of the printed output

When MSGLVL > 0, then F04QAF will produce output (except in the case where the routine fails with IFAIL = 1) on the advisory message channel (see X04ABF).

When MSGLVL >= 2 then a summary line is printed periodically giving the following information:

<table>
<thead>
<tr>
<th>Output</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>ITN</td>
<td>Iteration number, k.</td>
</tr>
<tr>
<td>X(1)</td>
<td>The first element of the current iterate x.</td>
</tr>
<tr>
<td>FUNCTION</td>
<td>The current value of the function, (rho), being minimized.</td>
</tr>
<tr>
<td>COMPAT</td>
<td>An estimate of</td>
</tr>
<tr>
<td>T</td>
<td></td>
</tr>
<tr>
<td>INCOMPAT</td>
<td>An estimate of</td>
</tr>
<tr>
<td>NRM(ABAR)</td>
<td>A monotonically increasing estimate of</td>
</tr>
<tr>
<td>COND(ABAR)</td>
<td>A monotonically increasing estimate of the condition number cond(A).</td>
</tr>
</tbody>
</table>

6. Error Indicators and Warnings

Errors detected by the routine:
IFAIL< 0
A negative value of IFAIL indicates an exit from F04QAF because the user has set MODE negative in APROD. The value of IFAIL will be the same as the user’s setting of MODE.

IFAIL= 1
On entry M < 1,
or N < 1,
or LRWORK < 1,
or LIWORK < 1.

IFAIL= 2
The condition of equation (3.8) has been satisfied for the value of c supplied in CONLIM. If this failure is unexpected the user should check that APROD is working correctly. Although conditions (3.6) or (3.7) have not been satisfied, the values returned in RNORM, ARNORM and XNORM may nevertheless indicate that an acceptable solution has been reached.

IFAIL= 3
The conditions of equation (3.8) has been satisfied for the value c = 1.0/(epsilon), where (epsilon) is the machine precision. The matrix A is nearly singular or rank deficient and the problem is too ill-conditioned for this machine. If this failure is unexpected, the user should check that APROD is working correctly.

IFAIL= 4
The limit on the number of iterations has been reached. The number of iterations required by F04QAF and the condition of the matrix A can depend strongly on the scaling of the problem. Poor scaling of the rows and columns of A should be avoided whenever possible.

7. Accuracy
When the problem is compatible, the computed solution x will satisfy the equation
\[ r = b - Ax, \]
where an estimate of \( ||r|| \) is returned in the parameter RNORM. When the problem is incompatible, the computed solution \( x \) will satisfy the equation

\[
T \\
A r = e,
\]
where an estimate of \( ||e|| \) is returned in the parameter ARNORM. See also Section 6.2 of Paige and Saunders [1].

8. Further Comments

The time taken by the routine is likely to be principally determined by the time taken in APROD, which is called twice on each iteration, once with \( \text{MODE} = 1 \) and once with \( \text{MODE} = 2 \). The time taken per iteration by the remaining operations in F04QAF is approximately proportional to \( \max(m,n) \).

The Lanczos process will usually converge more quickly if \( A \) is pre-conditioned by a non-singular matrix \( M \) that approximates \( A \) in some sense and is also chosen so that equations of the form \( My = c \) can efficiently be solved for \( y \). Some discussion of pre-conditioning in the context of symmetric matrices is given in Section 3 of the document for F04MBF. In the context of F04QAF, problem (3.1) is equivalent to

\[
-1 \\
(AM)^{-1} y = b, \quad Mx = y
\]
and problem (3.2) is equivalent to minimizing

\[
-1 \\
(\rho) = ||r||, \quad r = b - (AM)^{-1} y, \quad Mx = y.
\]

Note that the normal matrix \((AM)^{-1} (AM)^{-1} = M^{-1} (A^T A) M^{-1}\) so that the pre-conditioning \(AM^{-1}\) is equivalent to the pre-conditioning \(M^{-1} (A^T A) M^{-1}\) of the normal matrix \(A^T A\).

Pre-conditioning can be incorporated into F04QAF simply by coding the routine APROD to compute \( y + AM^{-1} x \) and \( x + M^{-1} A^T y \) in place of \( T y + Ax \) and \( x + A^T y \) respectively, and then solving the equations \( Mx = y \) for \( x \) on return from F04QAF. \( y + AM^{-1} x \) should be computed by
solving $Mz = x$ for $z$ and then computing $y + Az$, and $x + MAy$ should
be computed by solving $Mz = Ay$ for $z$ and then forming $x + z$.

9. Example

To solve the linear least-squares problem

$$\text{minimize } (\rho) = ||r||, \quad r = b - Ax$$

where $A$ is the 13 by 12 matrix and $b$ is the 13 element vector
given by

$$A = \begin{pmatrix}
1 & 0 & 0 & -1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & -1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & -1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
-1 & 0 & -1 & 4 & -1 & 0 & 0 & -1 & 0 & 0 & 0 & 0 \\
0 & -1 & 0 & -1 & 4 & -1 & 0 & 0 & -1 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & -1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\
\end{pmatrix}$$

$$b = -h \begin{pmatrix}
0 \\
1 \\
1 \\
0 \\
0 \\
0 \\
1 \\
0 \\
0 \\
1 \\
1 \\
1 \\
1 \\
\end{pmatrix}$$

with $h = 0.1$.

Such a problem can arise by considering the Neumann problem on a rectangle

$$(\Delta u) = 0$$
\[ \begin{align*}
\text{(delta)}u & \quad 2 \quad \text{(delta)}u \quad / \\
\text{(nabla)}u = g(x,y) & \quad \text{(delta)}n \quad / \\
\text{(delta)}n & \quad / \quad c
\end{align*} \]

where \( C \) is the boundary of the rectangle, and discretising as illustrated below with the square mesh

Please see figure in printed Reference Manual

The 12 by 12 symmetric part of \( A \) represents the difference equations and the final row comes from the normalising condition. The example program has \( g(x,y)=1 \) at all the internal mesh points, but apart from this is written in a general manner so that the number of rows (NROWS) and columns (NCOLS) in the grid can readily be altered.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
CHAPTER 22. NAG LIBRARY ROUTINES

Contents of this Introduction:

1. Scope of the Chapter

2. Background to the Problems
   2.1. The Use of BLAS Names
   2.2. Background Information
       2.2.1. Real plane rotations
   2.3. References

   4.1. The Level-0 Scalar Routines
   4.2. The Level-1 Vector Routines
   4.3. The Level-2 Matrix-vector Routines
   4.4. The Level-3 Matrix-matrix Routines

1. Scope of the Chapter

This Chapter is concerned with basic linear algebra routines which perform elementary algebraic operations involving scalars, vectors and matrices.

2. Background to the Problems
All the routines in this Chapter meet the specification of the Basic Linear Algebra Subprograms (BLAS) as described in Lawson et al [6], Dongarra et al [3] and [4]. The first reference describes a set of routines concerned with operations on scalars and vectors: these will be referred to here as the Level-0 and the Level-1 BLAS; the second reference describes a set of routines concerned with matrix-vector operations: these will be referred to here as the Level-2 BLAS; and the third reference describes a set of routines concerned with matrix-matrix operations: these will be referred to here as the Level-3 BLAS. The terminology reflects the number of operations involved. For example, a Level-2 routine involves \( O(n^2) \) operations for an \( n \times n \) matrix.

Table 1.1 indicates the naming scheme for the routines in this Chapter. The heading 'mixed type' is for routines where a mixture of data types is involved, such as a routine that returns the real Euclidean length of a complex vector.

```
Level-0  Level-1  Level-2  Level-3
'real' BLAS routine F06A F  F06E F  F06F F  F06Y F
'complex' BLAS routine -  F06G F  F06S F  F06Z F
```

Table 1.1

The routines in this chapter do not have full routine documents, but instead are covered by some relevant background material, in Section 2.2, together with general descriptions, in Section 4, sufficient to enable their use. As this chapter is concerned only with basic linear algebra operations, the routines will not normally be required by the general user. The functionality of each routine is indicated in Section 3 so that those users requiring these routines to build specialist linear algebra modules can determine which routines are of interest.

2.1. The Use of BLAS Names

Many of the routines in other chapters of the Library call the BLAS in this chapter. These routines are usually called by the BLAS name and so, for correct operation of the Library, it is essential that users do not attempt to link their own versions of these routines. If users are in any doubt about how to avoid this, please consult your local support staff or the NAG Response Centre.

The BLAS names are used in order to make use of efficient
implementations of the routines when these exist. Such implementations are stringently tested before being used, to ensure that they correctly meet the specification of the BLAS, and that they return the desired accuracy (see, for example, Dongarra et al. [3] and [4]).

2.2. Background Information

Most of the routines in this chapter implement straightforward scalar, vector and matrix operations that need no further explanation beyond a statement of the purpose of the routine. In this section we give some additional background information for those few cases where additional explanation may be necessary.

2.2.1. Real plane rotations

Two routines in the chapter are concerned with setting up and applying plane rotations. For further background information see Golub and Van Loan [5].

A plane rotation matrix for the (i,j) plane, \( R_{ij} \), is an orthogonal matrix that is different from the unit matrix only in the elements \( r_{ii} \), \( r_{jj} \), \( r_{ij} \) and \( r_{ji} \). If we put

\[
\begin{pmatrix}
  r_{ii} & r_{ij} \\
  r_{ji} & r_{jj}
\end{pmatrix},
\]

then, in the real case, it is usual to choose \( R_{ij} \) so that

\[
\begin{pmatrix}
  c & s \\
  -s & c
\end{pmatrix},
\]

where \( c = \cos(\theta) \), \( s = \sin(\theta) \). (2.1)

The application of plane rotations is straightforward and needs no further elaboration, so further comment is made only on the construction of plane rotations.

The most common use of plane rotations is to choose \( c \) and \( s \) so that for given \( a \) and \( b \),

\[
\begin{pmatrix}
  c & s \\
  -s & c
\end{pmatrix}\begin{pmatrix}
a \\
b
\end{pmatrix} = \begin{pmatrix} d \\ 0 \end{pmatrix} \quad (2.2)
\]

In such an application the matrix \( R \) is often termed a Givens
rotation matrix.

The BLAS routine F06AAF(*) (DROTG), see Lawson et al [6] and
Dodson and Grimes [1, 2], computes c, s and d as

\[
\begin{align*}
2 & 2 1/2 \\
d &= (\text{sign}(a + b)) d, \\
\{a/d, d=0 \} &= \{b/d, d=0 \} \\
c &= \{1, d=0 \}, \ s = \{0, d=0 \}
\end{align*}
\]

where \((\text{sign}) = \{\text{sign}(b), |a| \leq |b|\}.

The value \(z\) defined as

\[
\begin{align*}
\{s, |s| < c \text{ or } c = 0 \} \quad z &= \{1/c, 0 < |c| \leq s \} \\
(2.3)
\end{align*}
\]

is also computed and this enables \(c\) and \(s\) to be reconstructed
from the single value \(z\) as

\[
\begin{align*}
\{0, z = 1 \} \quad c &= \{(1-z), |z| < 1 \} \\
\{1, z = 1 \} \quad s &= \{z, |z| < 1 \} \\
\{2 \} \quad \{(1-c), |z| > 1 \}.
\end{align*}
\]

3. Recommendations on Choice and Use of Routines

This section lists the routines in each of the categories Level-0 (scalar), Level-1 (vector), Level-2 (matrix-vector and matrix) and Level-3 (matrix-matrix). The corresponding double precision BLAS name is indicated in brackets.

Within each section routines are listed in alphabetic order of the fifth character in the routine name, so that corresponding real and complex routines may have adjacent entries.

3.1. The Level-0 Scalar Routine

The Level-0 routine performs the scalar operation of generating a plane rotation.

F06AAF (DROTG) generates a real plane rotation.

3.2. The Level-1 Vector Routines

The Level-1 routines perform operations on or between vectors, such as computing dot products and Euclidean lengths.

F06EAF (DDOT) computes the dot product of two real vectors

F06GAF (ZDOTU) computes the dot product of two complex vectors (unconjugated)

F06GBF (ZDOTC) computes the dot product of two complex vectors (conjugated)

F06ECF (DAXPY) adds a scalar times a vector to another real vector

F06GCF (ZAXPY) adds a scalar times a vector to another complex vector

F06EDF (DSCAL) multiplies a real vector by a scalar

F06GDF (ZSCAL) multiplies a complex vector by a scalar

F06JDF (ZDSCAL) multiplies a complex vector by a real scalar

F06EFF (DCOPY) copies a real vector

F06GFF (ZCOPY) copies a complex vector
22.5. NAGF.HT

F06EGF (DSWAP) swaps two real vectors
F06GGF (ZSWAP) swaps two complex vectors
F06EJF (DNRM2) computes the Euclidean length of a real vector
F06JJF (DZNRM2) computes the Euclidean length of a complex vector
F06EKF (DASUM) sums the absolute values of the elements of a real vector
F06JKF (DZASUM) sums the absolute values of the elements of a complex vector
F06JLF (IDAMAX) finds the index of the element of largest absolute value of a real vector
F06JMF (IZAMAX) finds the index of the element of largest absolute value of a complex vector
F06EPF (DROT) applies a real plane rotation

3.3. The Level-2 Matrix-vector Routines

The Level-2 routines perform matrix-vector operations, such as forming the product between a matrix and a vector.

F06PAF (DGEMV) computes a matrix-vector product; real general matrix
F06SAF (ZGEMV) computes a matrix-vector product; complex general matrix
F06PBF (DGBMV) computes a matrix-vector product; real general band matrix
F06SBF (ZGBMV) computes a matrix-vector product; complex general band matrix
F06PCF (DSYMV) computes a matrix-vector product; real symmetric matrix
F06SCF (ZHEMV) computes a matrix-vector product; complex Hermitian matrix
F06PDF (DSBMV) computes a matrix-vector product; real symmetric band matrix
F06SDF (ZHBMV) computes a matrix-vector product; complex Hermitian band matrix
CHAPTER 22. NAG LIBRARY ROUTINES

F06PEF (DSPMV) computes a matrix-vector product; real symmetric packed matrix

F06SEF (ZHPMV) computes a matrix-vector product; complex Hermitian packed matrix

F06PFF (DTRMV) computes a matrix-vector product; real triangular matrix

F06SFF (ZTRMV) computes a matrix-vector product; complex triangular matrix

F06PGF (DTBMV) computes a matrix-vector product; real triangular band matrix

F06SGF (ZTBMV) computes a matrix-vector product; complex triangular band matrix

F06PHF (DTPMV) computes a matrix-vector product; real triangular packed matrix

F06SHF (ZTPMV) computes a matrix-vector product; complex triangular packed matrix

F06PJF (DTRSV) solves a system of equations; real triangular coefficient matrix

F06SJF (ZTRSV) solves a system of equations; complex triangular coefficient matrix

F06PKF (DTBSV) solves a system of equations; real triangular band coefficient matrix

F06SKF (ZTBSV) solves a system of equations; complex triangular band coefficient matrix

F06PLF (DTPSV) solves a system of equations; real triangular packed coefficient matrix

F06SLF (ZTPSV) solves a system of equations; complex triangular packed coefficient matrix

F06PMF (DGER) performs a rank-one update; real general matrix

F06SMF (ZGERU) performs a rank-one update; complex general matrix (unconjugated vector)

F06SNF (ZGERC) performs a rank-one update;
22.5. NAGF.HT

complex general matrix (conjugated vector)

F06PPF (DSYR) performs a rank-one update; real symmetric matrix

F06SPF (ZHER) performs a rank-one update; complex Hermitian matrix

F06PQF (DSPR) performs a rank-one update; real symmetric packed matrix

F06SQF (ZHPR) performs a rank-one update; complex Hermitian packed matrix

F06PRF (DSYR2) performs a rank-two update; real symmetric matrix

F06SRF (ZHER2) performs a rank-two update; complex Hermitian matrix

F06PSF (DSPR2) performs a rank-two update; real symmetric packed matrix

F06SSF (ZHPR2) performs a rank-two update; complex Hermitian packed matrix

3.4. The Level-3 Matrix-matrix Routines

The Level-3 routines perform matrix-matrix operations, such as forming the product of two matrices.

F06YAF (DGEMM) computes a matrix-matrix product; two real rectangular matrices

F06ZAF (ZGEMM) computes a matrix-matrix product; two complex rectangular matrices

F06YCF (DSYMM) computes a matrix-matrix product; one real symmetric matrix, one real rectangular matrix

F06ZCF (ZHEMM) computes a matrix-matrix product; one complex Hermitian matrix, one complex rectangular matrix

F06YFF (DTRMM) computes a matrix-matrix product; one real triangular matrix, one real rectangular matrix

F06ZFF (ZTRMM) computes a matrix-matrix product; one complex triangular matrix, one complex rectangular matrix

F06YJF (DTRSM) solves a system of equations with multiple right-
CHAPTER 22. NAG LIBRARY ROUTINES

hand sides, real triangular coefficient matrix

F06ZJF (ZTRSM) solves a system of equations with multiple right-hand sides, complex triangular coefficient matrix

F06YPF (DSYRK) performs a rank-k update of a real symmetric matrix

F06ZPF (ZHERK) performs a rank-k update of a complex Hermitian matrix

F06YRF (DSYR2K) performs a rank-2k update of a real symmetric matrix

F06ZRF (ZHER2K) performs a rank-2k update of a complex Hermitian matrix

F06ZTF (ZSYMM) computes a matrix-matrix product: one complex symmetric matrix, one complex rectangular matrix

F06ZUF (ZSYRK) performs a rank-k update of a complex symmetric matrix

F06ZWF (ZSYR2K) performs a rank-2k update of a complex symmetric matrix

4. Description of the F06 Routines

In this section we describe the purpose of each routine and give information on the parameter lists, where appropriate indicating their general nature. Usually the association between the routine arguments and the mathematical variables is obvious and in such cases a description of the argument is omitted.

Within each section, the parameter lists for all routines are presented, followed by the purpose of the routines and information on the parameter lists. The double precision BLAS names are given in ENTRY statements.

Within each section routines are listed in alphabetic order of the fifth character in the routine name, so that corresponding real and complex routines may have adjacent entries.

4.1. The Level-0 Scalar Routines

The scalar routines have no array arguments.

SUBROUTINE F06AAF( A,B,C,S )
ENTRY DROTG ( A,B,C,S )
22.5. NAGF.HT

DOUBLE PRECISION A,B,C,S

F06AAF(*) generates the parameters c and s of a Givens rotation as defined by equations (2.3) and (2.4), from given a and b. On exit, A is overwritten by d and B is overwritten by z.

4.2. The Level-1 Vector Routines

The vector routines all have one or more one-dimensional arrays as arguments, each representing a vector.

The length of each vector, n, is represented by the argument N, and the routines may be called with non-positive values of N, in which case the routine returns immediately except for the functions, which set the function value to zero before returning.

In addition to the argument N, each array argument is also associated with an increment argument that immediately follows the array argument, and whose name consists of the three characters INC, followed by the name of the array. For example, a vector x will be represented by the two arguments X, INCX. The increment argument is the spacing (stride) in the array for which the elements of the vector occur. For instance, if INCX = 2, then the elements of x are in locations X(1),X(3),...,X(2*N-1) of the array X and the intermediate locations X(2),X(4),...,X(2*N-2) are not referenced.

Thus when INCX > 0, the vector element x is in the array element \( i \) \( X(1+(i-1)*INCX) \). When INCX <= 0 the elements are stored in the reverse order so that the vector element x is in the array element \( i \) \( X(1-(n-i)*INCX) \) and hence, in particular, the element x \( n \) is in X(1). The declared length of the array X in the calling (sub)program must be at least \( (1+(N-1)*|INCX|) \).

Non-positive increments are permitted only for those routines that have more than one array argument. While zero increments are formally permitted for such routines, their use in Chapter F06 is strongly discouraged since the effect may be implementation dependent.

DOUBLE PRECISION X(*), Y(*), C, S
F06EAF(*) and F06GAF(*)

\[ T \]
return the dot product \( x^T y \).

F06GBF(*)

\[ H \]
returns the dot product \( x^H y \), where \( x^H \) denotes the complex \( T \)
conjugate of \( x \).

F06ECF(*) and F06GCF(*)
perform the operation \( y \leftarrow (\alpha)x + y \), often called an axpy
operation.

F06EDF(*), F06GDF(*) and F06JDF(*)
perform the operation \( x \leftarrow (\alpha)x \).

F06EFF(*) and F06GFF(*)
perform the operation \( y \leftarrow -x \).

F06EGF(*) and F06GGF(*)
perform the operation \( x \leftrightarrow y \), that is \( x \) and \( y \) are swapped.

F06EJF(*) and F06JJF(*)

\[ \frac{1}{\sqrt{n}} \quad (\text{n})^{1/2} \]
\[ (\text{--) 2} \]
return the value \( \|x\| \) defined by \( \|x\| = \sum_{i=1}^{n} |x_i| / 2 \).

F06EKF(*)

\[ n \quad -- \]
returns the value \( \|x\| \) defined by \( \|x\| = \sum_{i=1}^{n} |x_i| \).

F06JKF(*)

\[ n \quad -- \]
returns the value asum defined by \( \text{asum} = \sum_{i=1}^{n} (|\text{Re}(x)| + |\text{Im}(x)|) \).
22.5. NAGF.HT

\[ \begin{align*}
- \quad i & \quad i \\
\quad i & = 1
\end{align*} \]

F06JLF(*)

returns the first index \( j \) such that \( |x| = \max |x| \).

\[ \begin{align*}
\quad j & \quad i \\
\quad i &
\end{align*} \]

F06JMF(*)

returns the first index \( j \) such that
\[ |\text{Re}(x)| + |\text{Im}(x)| = \max (|\text{Re}(x)| + |\text{Im}(x)|). \]

\[ \begin{align*}
\quad j & \quad i \\
\quad i &
\end{align*} \]

F06EPF(*)

\[ \begin{align*}
\begin{pmatrix} T \end{pmatrix} & \begin{pmatrix} T \end{pmatrix} \\
\begin{pmatrix} x \end{pmatrix} & \begin{pmatrix} x \end{pmatrix} \\
\begin{pmatrix} T \end{pmatrix} & \begin{pmatrix} c \end{pmatrix} \begin{pmatrix} s \end{pmatrix} \begin{pmatrix} T \end{pmatrix}
\end{align*} \]

performs the plane rotation \( y \leftarrow (-s c) y \).

4.3. The Level-2 Matrix-vector Routines

The matrix-vector routines all have one array argument representing a matrix; usually this is a two-dimensional array but in some cases the matrix is represented by a one-dimensional array.

The size of the matrix is determined by the arguments \( M \) and \( N \) for an \( m \) by \( n \) rectangular matrix; and by the argument \( N \) for an \( n \) by \( n \) symmetric, Hermitian, or triangular matrix. Note that it is permissible to call the routines with \( M \) or \( N = 0 \), in which case the routines exit immediately without referencing their array arguments. For band matrices, the bandwidth is determined by the arguments \( KL \) and \( KU \) for a rectangular matrix with \( kl \) sub-diagonals and \( ku \) super-diagonals; and by the argument \( K \) for a symmetric, Hermitian, or triangular matrix with \( k \) sub-diagonals and/or super-diagonals.

The description of the matrix consists either of the array name (A) followed by the first dimension of the array as declared in the calling (sub)program (LDA), when the matrix is being stored in a two-dimensional array; or the array name (AP) alone when the matrix is being stored as a (packed) vector. In the former case the actual array must contain at least \((n-1)d+1\) elements, where \( d \) is the first dimension of the array, \( d \geq 1 \), and \( l = m \) for arrays representing general matrices, \( l = n \) for arrays representing symmetric, Hermitian and triangular matrices, \( l = k \) for band matrices and \( l = k + 1 \) for symmetric, Hermitian and triangular band matrices. For one-
dimensional arrays representing matrices (packed storage) the actual array must contain at least \(-n(n+1)\) elements.

As with the vector routines, vectors are represented by one-dimensional arrays together with a corresponding increment argument (see Section 4.2). The only difference is that for these routines a zero increment is not permitted.

When the vector \(x\) consists of \(k\) elements then the declared length of the array \(X\) in the calling (sub)program must be at least \((1+(k-1)|INCX|)\).

The arguments that specify options are character arguments with the names TRANS, UPLO and DIAG. TRANS is used by the matrix-vector product routines as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>'N' or 'n'</td>
<td>Operate with the matrix</td>
</tr>
<tr>
<td>'T' or 't'</td>
<td>Operate with the transpose of the matrix</td>
</tr>
<tr>
<td>'C' or 'c'</td>
<td>Operate with the conjugate transpose of the matrix</td>
</tr>
</tbody>
</table>

In the real case the values 'T', 't', 'C' and 'c' have the same meaning.

UPLO is used by the Hermitian, symmetric, and triangular matrix routines to specify whether the upper or lower triangle is being referenced as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>'U' or 'u'</td>
<td>Upper triangle</td>
</tr>
<tr>
<td>'L' or 'l'</td>
<td>Lower triangle</td>
</tr>
</tbody>
</table>

DIAG is used by the triangular matrix routines to specify whether or not the matrix is unit triangular, as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>'U' or 'u'</td>
<td>Unit triangular</td>
</tr>
<tr>
<td>'N' or 'n'</td>
<td>Non-unit triangular</td>
</tr>
</tbody>
</table>

When DIAG is supplied as 'U' or 'u' the diagonal elements are not
It is worth noting that actual character arguments in Fortran may be longer than the corresponding dummy arguments. So that, for example, the value 'T' for TRANS may be passed as 'TRANSPOSE'.

The routines for real symmetric and complex Hermitian matrices allow for the matrix to be stored in either the upper (UPLO = 'U') to be packed in a one-dimensional array. In the latter case the upper triangle may be packed sequentially column by column (UPLO = 'U'), or the lower triangle may be packed sequentially column by column (UPLO = 'L'). Note that for real symmetric matrices packing the upper triangle by column is equivalent to packing the lower triangle by rows, and packing the lower triangle by columns is equivalent to packing the upper triangle by rows. (For complex Hermitian matrices the only difference is that the off-diagonal elements are conjugated.)

For triangular matrices the argument UPLO serves to define whether the matrix is upper (UPLO = 'U') or lower (UPLO = 'L') triangular. In packed storage the triangle has to be packed by column.

The band matrix routines allow storage so that the jth column of the matrix is stored in the jth column of the Fortran array. For a general band matrix the diagonal of the matrix is stored in the (ku+1)th row of the array. For a Hermitian or symmetric matrix either the upper triangle (UPLO = 'U') may be stored in which case the leading diagonal is in the (k+1)th row of the array, or the lower triangle (UPLO = 'L') may be stored in which case the leading diagonal is in the first row of the array. For an upper triangular band matrix (UPLO = 'U') the leading diagonal is in the (k+1)th row of the array and for a lower triangular band matrix (UPLO = 'L') the leading diagonal is in the first row.

For a Hermitian matrix the imaginary parts of the diagonal elements are of course zero and thus the imaginary parts of the corresponding Fortran array elements need not be set, but are assumed to be zero.

For packed triangular matrices the same storage layout is used whether or not DIAG = 'U', i.e., space is left for the diagonal elements even if those array elements are not referenced.

Throughout the following sections A denotes the complex conjugate of A.

where \( A \) is a triangular matrix for F06PFF(*) and F06SFF(*), is a triangular matrix stored in packed form for F06PHF(*) and F06SHF(*), and is a triangular band matrix for F06PGF(*) and F06SGF(*)

F06PJF(*), F06SJF(*), F06PLF(*), F06SLF(*), F06PKF(*) and F06SKF(*) solve the equations

\[ Ax = b, \text{ when } TRANS = 'N', \]

\[ T \]
A x = b, \quad \text{when TRANS = 'T'},

H A x = b, \quad \text{when TRANS = 'C'},

where A is a triangular matrix for F06PJF(*) and F06SJF(*), is a triangular matrix stored in packed form for F06PLF(*) and F06SLF(*), and is a triangular band matrix for F06PKF(*) and F06SKF(*). The vector b must be supplied in the array X and is overwritten by the solution. It is important to note that no test for singularity is included in these routines.

F06PMF(*) and F06SMF(*)

T
perform the operation A \leftarrow (\alpha) xy + A, where A is a general matrix.

F06SNF(*)

H
performs the operation A \leftarrow (\alpha) xy + A, where A is a general complex matrix.

F06PPF(*) and F06PQF(*)

T
perform the operation A \leftarrow (\alpha) xx + A, where A is a symmetric matrix for F06PPF(*) and is a symmetric matrix stored in packed form for F06PQF(*)

F06SPF(*) and F06SQF(*)

H
perform the operation A \leftarrow (\alpha) xx + A, where A is an Hermitian matrix for F06SPF(*) and is an Hermitian matrix stored in packed form for F06SQF(*)

F06PRF(*) and F06PSF(*)

T

T
perform the operation A \leftarrow (\alpha) xy + (\alpha) yx + A, where A is a symmetric matrix for F06PRF(*) and is a symmetric matrix stored in packed form for F06PSF(*)

F06SRF(*) and F06SSF(*)

H

H
perform the operation A \leftarrow (\alpha) xy + (\alpha) yx + A, where A is an Hermitian matrix for F06SRF(*) and is an Hermitian matrix stored
in packed form for F06SSF(*)).

The following argument values are invalid:

Any value of the character arguments DIAG, TRANS, or UPL0 whose meaning is not specified.

\[ M < 0 \]
\[ N < 0 \]
\[ KL < 0 \]
\[ KU < 0 \]
\[ K < 0 \]
\[ LDA < M \]
\[ LDA < KL + KU + 1 \]
\[ LDA < N \text{ for the routines involving full Hermitian, symmetric or triangular matrices} \]
\[ LDA < K + 1 \text{ for the routines involving band Hermitian, symmetric or triangular matrices} \]
\[ INCX = 0 \]
\[ INCY = 0 \]

If a routine is called with an invalid value then an error message is output, on the error message unit (see X04AAF), giving the name of the routine and the number of the first invalid argument, and execution is terminated.

4.4. The Level-3 Matrix-matrix Routines

The matrix-matrix routines all have either two or three arguments representing a matrix, one of which is an input-output argument, and in each case the arguments are two-dimensional arrays.

The sizes of the matrices are determined by one or more of the arguments M, N and K. The size of the input-output array is always determined by the arguments M and N for a rectangular m by n matrix, and by the argument N for a square n by n matrix. It is permissible to call the routines with M or N = 0, in which case the routines exit immediately without referencing their array arguments.
Many of the routines perform an operation of the form
\[ C \leftarrow P + (\beta)C, \]
where \( P \) is the product of two matrices, or the sum of two such products. When the inner dimension of the matrix product is different from \( m \) or \( n \) it is denoted by \( K \). Again it is permissible to call the routines with \( K = 0 \) and if \( M > 0 \), but \( K = 0 \), then the routines perform the operation
\[ C \leftarrow (\beta)C. \]

As with the Level-2 routines (see Section 4.3) the description of the matrix consists of the array name (\( A \) or \( B \) or \( C \)) followed by the first dimension (\( LDA \) or \( LDB \) or \( LDC \)).

The arguments that specify options are character arguments with the names \( SIDE, TRANSA, TRANSB, TRANS, UPL0 \) and \( DIAG \). \( UPL0 \) and \( DIAG \) have the same values and meanings as for the Level-2 routines (see Section 4.3); \( TRANS, TRANSB \) and \( TRANS \) have the same values and meanings as \( TRANS \) in the Level-2 routines, where \( TRANSA \) and \( TRANSB \) apply to the matrices \( A \) and \( B \) respectively. \( SIDE \) is used by the routines as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>'L'</td>
<td>Multiply general matrix by symmetric, Hermitian or triangular matrix on the left</td>
</tr>
<tr>
<td>'R'</td>
<td>Multiply general matrix by symmetric, Hermitian or triangular matrix on the right</td>
</tr>
</tbody>
</table>

The storage conventions for matrices are as for the Level-2 routines (see Section 4.3).

where \( A \) is a general matrix and \( C \) is an \( n \) by \( n \) symmetric matrix for \( \text{F06YRF}(*) \) and \( \text{F06ZRF}(*) \), and is an \( n \) by \( n \) Hermitian matrix for \( \text{F06ZRF}(*) \).
CHAPTER 22. NAG LIBRARY ROUTINES

F06ZWF  C <- (alpha)AB  C <- (alpha)A B  --
       T     T
       +(alpha)BA  +(alpha)B A
       +(beta)C    +(beta)C

F06ZRF  C <- (alpha)AB  --  C <- (alpha)A B
       H     H
       +(alpha)BA  +(alpha)B A
       +(beta)C    +(beta)C

A and B are n*k  A and B are k*n  A and B are k*n

where A and B are general matrices and C is an n by n symmetric
matrix for F06YRF(*) and F06ZWF(*), and is an n by n Hermitian
matrix for F06ZPF(*).

The following values of arguments are invalid:

Any value of the character arguments SIDE, TRANSA, TRANSB,
TRANS, UPLO or DIAG, whose meaning is not specified.

M < 0
N < 0
K < 0

LDA < the number of rows in the matrix A.

LDB < the number of rows in the matrix B.

LDC < the number of rows in the matrix C.

If a routine is called with an invalid value then an error
message is output, on the error message unit (see X04AAF), giving
the name of the routine and the number of the first invalid
argument, and execution is terminated.

F06SRF (ZHER2) Rank-2 update, complex Hermitian matrix
F06SSF (ZHPRT2) Rank-2 update, complex Hermitian packed matrix
F06YAF (DGEMM) Matrix-matrix product, two real rectangular matrices
F06YCF (DSYMM) Matrix-matrix product, one real symmetric matrix, one real rectangular matrix
F06YFF (DTRMM) Matrix-matrix product, one real triangular matrix, one real rectangular matrix
F06YJF (DTRSM) Solves a system of equations with multiple right-hand sides, real triangular coefficient matrix
F06YPF (DSYRK) Rank-k update of a real symmetric matrix
F06YRF (DSYR2K) Rank-2k update of a real symmetric matrix
F06ZAF (ZGEMM) Matrix-matrix product, two complex rectangular matrices
F06ZCF (ZHEMM) Matrix-matrix product, one complex Hermitian matrix, one complex rectangular matrix
F06ZFF (ZTRMM) Matrix-matrix product, one complex triangular matrix, one complex rectangular matrix
F06ZJF (ZTRSM) Solves system of equations with multiple right-hand sides, complex triangular coefficient matrix
F06ZPF (ZHERK) Rank-k update of a complex Hermitian matrix
F06ZRF (ZHER2K) Rank-2k update of a complex Hermitian matrix
F06ZTF (ZSYMM) Matrix-matrix product, one complex symmetric matrix
matrix, one complex rectangular matrix

F06ZUF (ZSYRK) Rank-k update of a complex symmetric matrix

F06ZWF (ZSYR2K) Rank-2k update of a complex symmetric matrix
Routine F07ADF (DGETRF) performs an LU factorization of a real m by n matrix A. Following the use of this routine, F07AEF (DGETRS) may be used to solve a system of n non-singular linear equations, with one or more right-hand sides.

Routine F07FDF (DPOTRF) performs the Cholesky factorization of a real symmetric positive-definite matrix A. Following the use of this routine, F07FEF (DPOTRS) may be used to solve a system of symmetric positive-definite linear equations, with one or more right-hand sides.

Computes the LU factorization of a real m by n matrix
F07ADF (DGETRF) computes the LU factorization of a real m by n matrix.

2. Specification

SUBROUTINE F07ADF (M, N, A, LDA, IPIV, INFO)
ENTRY M, N, A, LDA, IPIV, INFO
INTEGER M, N, LDA, IPIV(*), INFO
DOUBLE PRECISION A(LDA,*)

The ENTRY statement enables the routine to be called by its LAPACK name.

3. Description

This routine forms the LU factorization of a real m by n matrix A as A=PLU, where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if m>n) and U is upper triangular (upper trapezoidal if m<n). Usually A is square (m=n), and both L and U are triangular. The routine uses partial pivoting, with row interchanges.

4. References

5. Parameters

1: M -- INTEGER
   On entry: m, the number of rows of the matrix A.
   Constraint: M >= 0.

2: N -- INTEGER
   On entry: n, the number of columns of the matrix A.
Constraint: \( N \geq 0 \).

3: \( A(LDA,*) \) -- DOUBLE PRECISION array

Input/Output
Note: the second dimension of the array \( A \) must be at least \( \max(1,N) \).
On entry: the \( m \) by \( n \) matrix \( A \). On exit: \( A \) is overwritten by the factors \( L \) and \( U \); the unit diagonal elements of \( L \) are not stored.

4: \( LDA \) -- INTEGER

Input
On entry:
the first dimension of the array \( A \) as declared in the (sub)program from which \( \text{F07ADF} \) is called.
Constraint: \( LDA \geq \max(1,M) \).

5: \( \text{IPIV}(*) \) -- INTEGER array

Output
Note: the dimension of the array \( \text{IPIV} \) must be at least \( \max(1,\min(M,N)) \).
On exit: the pivot indices. Row \( i \) of the matrix \( A \) was interchanged with row \( \text{IPIV}(i) \) for \( i=1,2,\ldots,\min(m,n) \).

6: \( \text{INFO} \) -- INTEGER

Output
On exit: \( \text{INFO} = 0 \) unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

\( \text{INFO} < 0 \)
If \( \text{INFO} = -i \), the \( i \)th parameter has an illegal value. An explanatory message is output, and execution of the program is terminated.

\( \text{INFO} > 0 \)
If \( \text{INFO} = i \), \( u_{ii} \) is exactly zero. The factorization has been completed but the factor \( U \) is exactly singular, and division by zero will occur if it is subsequently used to solve a \( -1 \) system of linear equations or to compute \( A^{-1} \).

7. Accuracy

The computed factors \( L \) and \( U \) are the exact factors of a perturbed matrix \( A+E \), where

\[
|E| \leq c(n)(\epsilon)\|L\|\|U\|,
\]

\( c(n) \) is a modest linear function of \( n \), and \( (\epsilon) \) is the machine precision.
8. Further Comments

The total number of floating-point operations is approximately
\[ 2^{3} \cdot 1^2 \cdot 2 \]
- \( n \) if \( m=n \) (the usual case), \[ -n \cdot (3m-n) \] if \( m>n \) and \[ -m \cdot (3n-m) \] if \( m<n \).

A call to this routine with \( m=n \) may be followed by calls to the routines:

\[ T \]

F07AEF (DGETRS) to solve \( AX=B \) or \( A^TX=B \);

F07AGF (DGECON)\(^*\) to estimate the condition number of \( A \);

F07AJF (DGETRI)\(^*\) to compute the inverse of \( A \).

The complex analogue of this routine is F07ARF (ZGETRF)\(^*\).

9. Example

To compute the LU factorization of the matrix \( A \), where

\[
\begin{pmatrix}
1.80 & 2.88 & 2.05 & -0.89 \\
5.25 & -2.95 & -0.95 & -3.80 \\
1.58 & -2.69 & -2.90 & -1.04 \\
-1.11 & -0.66 & -0.59 & 0.80
\end{pmatrix}
\]

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
1. Purpose

F07AEF (DGETRS) solves a real system of linear equations with
multiple right-hand sides, AX=B or A X=B, where A has been
factorized by F07ADF (DGETRF).

2. Specification

SUBROUTINE F07AEF (TRANS, N, NRHS, A, LDA, IPIV, B, LDB,
1        INFO)
ENTRY TRANS, N, NRHS, A, LDA, IPIV, B, LDB, INFO
INTEGER N, NRHS, LDA, IPIV(*), LDB, INFO
DOUBLE PRECISION A(LDA,*), B(LDB,*)
CHARACTER*1 TRANS

The ENTRY statement enables the routine to be called by its
LAPACK name.

3. Description

To solve a real system of linear equations AX=B or A X=B, this
routine must be preceded by a call to F07ADF (DGETRF) which
computes the LU factorization of A as A=PLU. The solution is
computed by forward and backward substitution.

If TRANS = 'N', the solution is computed by solving PLY=B and
then UX=Y.

If TRANS = 'T' or 'C', the solution is computed by solving U Y=B
and then L P X=Y.

4. References
5. Parameters

1: TRANS -- CHARACTER*1  
   Input
   On entry: indicates the form of the equations as follows:
   if TRANS = 'N', then AX=B is solved for X;
       T
   if TRANS = 'T' or 'C', then A X=B is solved for X.
   Constraint: TRANS = 'N', 'T' or 'C'.

2: N -- INTEGER  
   Input
   On entry: n, the order of the matrix A. Constraint: N >= 0.

3: NRHS -- INTEGER  
   Input
   On entry: r, the number of right-hand sides. Constraint: NRHS >= 0.

4: A(LDA,*) -- DOUBLE PRECISION array  
   Input
   Note: the second dimension of the array A must be at least
       max(1,N).
   On entry: the LU factorization of A, as returned by F07ADF
       (DGETRF).

5: LDA -- INTEGER  
   Input
   On entry: the first dimension of the array A as declared in the
   (sub)program from which F07AEF is called.
   Constraint: LDA >= max(1,N).

6: IPIV(*) -- INTEGER array  
   Input
   Note: the dimension of the array IPIV must be at least
       max(1,N).
   On entry: the pivot indices, as returned by F07ADF (DGETRF).

7: B(LDB,*) -- DOUBLE PRECISION array  
   Input/Output
   Note: the second dimension of the array B must be at least
       max(1,NRHS).
   On entry: the n by r right-hand side matrix B. On exit: the
   n by r solution matrix X.

8: LDB -- INTEGER  
   Input
   On entry: the first dimension of the array B as declared in the
   (sub)program from which F07AEF is called.
   Constraint: LDB >= max(1,N).
9:  INFO -- INTEGER  
    Output
    On exit: INFO = 0 unless the routine detects an error (see
Section 6).

6. Error Indicators and Warnings

INFO < 0
If INFO = -i, the ith parameter has an illegal value. An
explanatory message is output, and execution of the program
is terminated.

7. Accuracy

For each right-hand side vector b, the computed solution x is the
exact solution of a perturbed system of equations (A+E)x=b, where

\[ |E| \leq c(n)(\text{epsilon})P|L||U|, \]

\( c(n) \) is a modest linear function of \( n \), and \( \text{epsilon} \) is the
machine precision.

If \( x \) is the true solution, then the computed solution \( x \) satisfies
a forward error bound of the form

\[ \frac{||x-x||}{||x||} \leq c(n)\text{cond}(A,x)(\text{epsilon}) \]

where \( \text{cond}(A,x) = \frac{||A|||x||}{||x||} \) <= \( \text{cond}(A) \).

Forward and backward error bounds can be computed by calling
F07AHF (DGERFS)(*), and an estimate for \( (\kappa) (A) \) can be
obtained by calling F07AGF (DGECON)(*) with NORM = 'I'.

8. Further Comments
The total number of floating-point operations is approximately
\[ 2 \times n \times r. \]
This routine may be followed by a call to F07AHF (DGERFS)(*) to
refine the solution and return an error estimate.

The complex analogue of this routine is F07ASF (ZGETRS)(*).

9. Example

To solve the system of equations \( AX = B \), where

\[
\begin{pmatrix}
1.80 & 2.88 & 2.05 & -0.89 \\
5.25 & -2.95 & -0.95 & -3.80 \\
1.58 & -2.69 & -2.90 & -1.04 \\
-1.11 & -0.66 & -0.59 & 0.80
\end{pmatrix}
\]

and

\[
\begin{pmatrix}
9.52 & 18.47 \\
24.35 & 2.25 \\
0.77 & -13.28 \\
-6.22 & -6.21
\end{pmatrix}
\]

Here \( A \) is unsymmetric and must first be factorized by F07ADF
(DGETRF)).

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F07FDF (DPOTRF) computes the Cholesky factorization of a real symmetric positive-definite matrix.

2. Specification

   SUBROUTINE F07FDF (UPLO, N, A, LDA, INFO)
   ENTRY UPLO, N, A, LDA, INFO
   INTEGER N, LDA, INFO
   DOUBLE PRECISION A(LDA,*)
   CHARACTER*1 UPLO
   The ENTRY statement enables the routine to be called by its LAPACK name.

3. Description

   This routine forms the Cholesky factorization of a real symmetric positive-definite matrix $A$ either as $A=U^T U$ if $UPLO = 'U'$ or $A=L^T L$ if $UPLO = 'L'$, where $U$ is an upper triangular matrix and $L$ is lower triangular.

4. References

5. Parameters
1: UPLO -- CHARACTER*1
   On entry: indicates whether the upper or lower triangular
   part of A is stored and how A is factorized, as follows:
   if UPLO = 'U', then the upper triangular part of A is
   stored and A is factorized as U U, where U is upper
   triangular;
   if UPLO = 'L', then the lower triangular part of A is
   stored and A is factorized as LL, where L is lower
   triangular.
   Constraint: UPLO = 'U' or 'L'.

2: N -- INTEGER
   On entry: n, the order of the matrix A. Constraint: N >= 0.

3: A(LDA,*) -- DOUBLE PRECISION array
   Note: the second dimension of the array A must be at least
   max(1,N).
   On entry: the n by n symmetric positive-definite matrix A.
   If UPLO = 'U', the upper triangle of A must be stored and
   the elements of the array below the diagonal are not
   referenced; if UPLO = 'L', the lower triangle of A must be
   stored and the elements of the array above the diagonal are
   not referenced. On exit: the upper or lower triangle of A is
   overwritten by the Cholesky factor U or L as specified by
   UPLO.

4: LDA -- INTEGER
   On entry: the first dimension of the array A as declared in the
   (sub)program from which F07FDF is called.
   Constraint: LDA >= max(1,N).

5: INFO -- INTEGER
   On exit: INFO = 0 unless the routine detects an error (see
   Section 6).

6. Error Indicators and Warnings

   INFO < 0
   If INFO = -i, the i-th parameter has an illegal value. An
   explanatory message is output, and execution of the program
   is terminated.

   INFO > 0
   If INFO = i, the leading minor of order i is not positive-
   definite and the factorization could not be completed. Hence
   A itself is not positive-definite. This may indicate an
error in forming the matrix $A$. To factorize a symmetric matrix which is not positive-definite, call F07MDF (DSYTRF)(*) instead.

7. Accuracy

If UPLO = 'U', the computed factor $U$ is the exact factor of a perturbed matrix $A+E$, where

$$
|E| \leq c(n)(\text{epsilon})|U| |U|,
$$

$c(n)$ is a modest linear function of $n$, and (epsilon) is the machine precision. If UPLO = 'L', a similar statement holds for the computed factor $L$. It follows that

$$
|e_{ij}| \leq c(n)(\text{epsilon}) |a_{ii}a_{jj}|
$$

8. Further Comments

The total number of floating-point operations is approximately $13^{-n}$. A call to this routine may be followed by calls to the routines:

F07FEF (DPOTRS) to solve $AX=B$;

F07FGF (DPOCON)(*) to estimate the condition number of $A$;

F07FJF (DPOTRI)(*) to compute the inverse of $A$.

The complex analogue of this routine is F07FRF (ZPOTRF)(*).

9. Example

To compute the Cholesky factorization of the matrix $A$, where

$\begin{bmatrix}
  4.16 & -3.12 & 0.56 & -0.10 \\
  -3.12 & 5.03 & -0.83 & 1.18 \\
  0.56 & -0.83 & 0.76 & 0.34 \\
  -0.10 & 1.18 & 0.34 & 1.18
\end{bmatrix}$

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
Real symmetric positive-definite system of linear equations

---

---

---

---

---

---

---

---

---

---

---
To solve a real symmetric positive-definite system of linear equations \( AX = B \), this routine must be preceded by a call to F07FDF (DPOTRF) which computes the Cholesky factorization of \( A \). The solution \( X \) is computed by forward and backward substitution.

If \( \text{UPLO} = 'U' \), \( A = U^T U \), where \( U \) is upper triangular; the solution \( X \) is computed by solving \( U^T Y = B \) and then \( UX = Y \).

If \( \text{UPLO} = 'L' \), \( A = L L^T \), where \( L \) is lower triangular; the solution \( X \) is computed by solving \( LY = B \) and then \( L^T X = Y \).

4. References

5. Parameters

1: \text{UPLO} -- CHARACTER*1 Input
On entry: indicates whether the upper or lower triangular part of \( A \) is stored and how \( A \) is factorized, as follows:

\[ T \]
if \( \text{UPLO} = 'U' \), then \( A = U^T U \) where \( U \) is upper triangular;

\[ T \]
if \( \text{UPLO} = 'L' \), then \( A = LL^T \) where \( L \) is lower triangular.
Constraint: \( \text{UPLO} = 'U' \) or 'L'.

2: \text{N} -- INTEGER Input
On entry: \( n \), the order of the matrix \( A \). Constraint: \( N \geq 0 \).

3: \text{NRHS} -- INTEGER Input
On entry: \( r \), the number of right-hand sides. Constraint: \( \text{NRHS} \geq 0 \).

4: \( A(\text{LDA},*) \) -- DOUBLE PRECISION array Input
Note: the second dimension of the array \( A \) must be at least \( \max(1,N) \).
On entry: the Cholesky factor of \( A \), as returned by F07FDF (DPOTRF).

5: \text{LDA} -- INTEGER Input
On entry: the first dimension of the array \( A \) as declared in the (sub)program from which F07FEF is called.
Constraint: \( \text{LDA} \geq \max(1, N) \).

6: \( B(\text{LDB},*) \) -- DOUBLE PRECISION array Input/Output
Note: the second dimension of the array \( B \) must be at least \( \max(1, \text{NRHS}) \).
On entry: the \( n \) by \( r \) right-hand side matrix \( B \).

7: \( \text{LDB} \) -- INTEGER Input
On entry:
the first dimension of the array \( B \) as declared in the
(sub)program from which \( \text{F07FEF} \) is called.
Constraint: \( \text{LDB} \geq \max(1, N) \).

8: \( \text{INFO} \) -- INTEGER Output
On exit: \( \text{INFO} = 0 \) unless the routine detects an error (see
Section 6).

6. Error Indicators and Warnings

\( \text{INFO} < 0 \)
If \( \text{INFO} = -i \), the \( i \)th parameter has an illegal value. An
explanatory message is output, and execution of the program
is terminated.

7. Accuracy

For each right-hand side vector \( b \), the computed solution \( x \) is the
exact solution of a perturbed system of equations \( (A+E)x = b \), where

\[
T
|E| \leq c(n)(\epsilon)|U||U| \text{ if } \text{UPLO} = 'U',
\]

\[
T
|E| \leq c(n)(\epsilon)|L||L| \text{ if } \text{UPLO} = 'L',
\]

\( c(n) \) is a modest linear function of \( n \), and \( (\epsilon) \) is the
machine precision.

If \( x \) is the true solution, then the computed solution \( x \) satisfies
a forward bound of the form

\[
\frac{||x-x||}{||x||} \leq c(n)\text{cond}(A,x)(\epsilon)
\]
where \( \text{cond}(A,x) = \frac{|||A||x||}{||x||} \leq \infty \infty \)

\[-1\]

\( \text{cond}(A) = \frac{|||A||||}{||A||} \leq (\kappa) (A) \). Note that \( \text{cond}(A,x) \infty \infty \) can be much smaller than \( \text{cond}(A) \).

Forward and backward error bounds can be computed by calling \( \text{F07FHF (DPORFS)}(*) \), and an estimate for \( (\kappa) (A) \) \( \infty \infty \) = \( (\kappa) (A) \) can be obtained by calling \( \text{F07FGF (DPOCON)}(*) \).

8. Further Comments

The total number of floating-point operations is approximately

\[ 2n^3 \]

This routine may be followed by a call to \( \text{F07FHF (DPORFS)}(*) \) to refine the solution and return an error estimate.

The complex analogue of this routine is \( \text{F07FSF (ZPOTRS)}(*) \).

9. Example

To compute the Cholesky factorization of the matrix \( A \), where

\[
\begin{bmatrix}
4.16 & -3.12 & 0.56 & -0.10 \\
-3.12 & 5.03 & -0.83 & 1.18 \\
0.56 & -0.83 & 0.76 & 0.34 \\
-0.10 & 1.18 & 0.34 & 1.18
\end{bmatrix}
\]

and

\[
\begin{bmatrix}
8.70 & 8.30 \\
-13.35 & 2.13 \\
1.89 & 1.61 \\
-4.14 & 5.00
\end{bmatrix}
\]

Here \( A \) is symmetric positive-definite and must first be factorized by \( \text{F07FDF (DPOTRF)} \).

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
1. Scope of the Chapter

This chapter is concerned with sorting numeric data. It handles only the simplest types of data structure and it is concerned only with internal sorting -- that is, sorting a set of data which can all be stored within the program.

Users with large files of data or complex data structures to be sorted should use a comprehensive sorting program or package.

2. Background to the Problems

The usefulness of sorting is obvious (perhaps a little too obvious, since sorting can be expensive and is sometimes done when not strictly necessary). Sorting may traditionally be associated with data-processing and non-numerical programming, but it has many uses within the realm of numerical analysis, for example, to arrange eigenvalues in ascending order of absolute value and in the ranking of observations for nonparametric statistics.

The general problem may be defined as follows. We are given \( N \) items of data

\[ R_1, R_2, \ldots, R_N. \]

Each item \( R_i \) contains a key \( K_i \) which can be ordered relative to any other key according to some specified criterion (for example, ascending numeric value). The problem is to determine a
22.5. NAGF.HT

A permutation

\[ p(1), p(2), \ldots, p(N) \]

which puts the keys in order:

\[ K \leq K \leq \ldots \leq K \]

\[ p(1) \quad p(2) \quad \ldots \quad p(N) \]

Sometimes we may wish actually to rearrange the items so that their keys are in order; for other purposes we may simply require a table of indices so that the items can be referred to in sorted order; or yet again we may require a table of ranks, that is, the positions of each item in the sorted order.

For example, given the single-character items, to be sorted into alphabetic order:

\[ E \quad B \quad A \quad D \quad C \]

the indices of the items in sorted order are

\[ 3 \quad 2 \quad 5 \quad 4 \quad 1 \]

and the ranks of the items are

\[ 5 \quad 2 \quad 1 \quad 4 \quad 3 \]

Indices may be converted to ranks, and vice versa, by simply computing the inverse permutation.

The items may consist solely of the key (each item may simply be a number). On the other hand, the items may contain additional information (for example, each item may be an eigenvalue of a matrix and its associated eigenvector, the eigenvalue being the key). In the latter case there may be many distinct items with equal keys, and it may be important to preserve the original order among them (if this is achieved, the sorting is called 'stable').

There are a number of ingenious algorithms for sorting. For a fascinating discussion of them, and of the whole subject, see Knuth [1].

2.1. References

3. Recommendations on Choice and Use of Routines

Four categories of routines are provided:

- routines which rearrange the data into sorted order (M01C-);
- routines which determine the ranks of the data, leaving the data unchanged (M01D-);
- routines which rearrange the data according to pre-determined ranks (M01E-);
- service routines (M01Z-).

Routines are provided for sorting double precision data only.

If the task is simply to rearrange a one-dimensional array of data into sorted order, then M01CAF should be used, since this requires no extra workspace and is faster than any other method.

For many applications it is in fact preferable to separate the task of determining the sorted order (ranking) from the task of rearranging data into a pre-determined order; the latter task may not need to be performed at all. Frequently it may be sufficient to refer to the data in sorted order via an index vector, without rearranging it. Frequently also one set of data (e.g. a column of a matrix) is used for determining a set of ranks, which are then applied to other data (e.g. the remaining columns of the matrix).

To determine the ranks of a set of data, use an M01D- routine. Routines are provided for ranking one-dimensional arrays, and for ranking rows or columns of two-dimensional arrays.

To create an index vector so that data can be referred to in sorted order, first call an M01D- routine to determine the ranks, and then call M01ZAF to convert the vector of ranks into an index vector.

To rearrange data according to pre-determined ranks: use M01EAF if the data is stored in a one-dimensional array; or if the data is stored in a more complicated structure, use an index vector to generate a new copy of the data in the desired order.

Examples of these operations can be found in the routine documents of the relevant routines.

4. Index

Ranking:

  columns of a matrix, double precision numbers  M01DJF
Sort vector of double precision numbers

— nagm.ht —
Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

M01CAF rearranges a vector of double precision numbers into ascending or descending order.

2. Specification

```fortran
SUBROUTINE M01CAF (RV, M1, M2, ORDER, IFAIL)
INTEGER M1, M2, IFAIL
DOUBLE PRECISION RV(M2)
CHARACTER*1 ORDER
```

3. Description

M01CAF is based on Singleton’s implementation of the ‘median-of-three’ Quicksort algorithm [2], but with two additional modifications. First, small subfiles are sorted by an insertion sort on a separate final pass (Sedgewick [1]). Second, if a subfile is partitioned into two very unbalanced subfiles, the larger of them is flagged for special treatment: before it is partitioned, its end-points are swapped with two random points within it; this makes the worst case behaviour extremely unlikely.

4. References

5. Parameters

1: RV(M2) -- DOUBLE PRECISION array Input/Output
On entry: elements M1 to M2 of RV must contain double precision values to be sorted. On exit: these values are rearranged into sorted order.

2: M1 -- INTEGER Input
On entry: the index of the first element of RV to be sorted.
Constraint: \( M1 > 0 \).

3: \( M2 \) -- INTEGER  
Input

On entry: the index of the last element of RV to be sorted.
Constraint: \( M2 \geq M1 \).

4: \( \text{ORDER} \) -- CHARACTER*1  
Input
On entry: if \( \text{ORDER} \) is 'A', the values will be sorted into ascending (i.e., non-decreasing) order; if \( \text{ORDER} \) is 'D', into descending order. Constraint: \( \text{ORDER} = 'A' \) or 'D'.

5: \( \text{IFAIL} \) -- INTEGER  
Input/Output
On entry: \( \text{IFAIL} \) must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: \( \text{IFAIL} = 0 \) unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry \( \text{IFAIL} = 0 \) or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

\( \text{IFAIL} = 1 \)

On entry \( M2 < 1 \),

or \( M1 < 1 \),

or \( M1 > M2 \).

\( \text{IFAIL} = 2 \)

On entry \( \text{ORDER} \) is not 'A' or 'D'.

7. Accuracy

Not applicable.

8. Further Comments

The average time taken by the routine is approximately proportional to \( n \log n \), where \( n = M2 - M1 + 1 \). The worst case time is proportional to \( n^2 \) but this is extremely unlikely to occur.
9. Example

The example program reads a list of double precision numbers and sorts them into ascending order.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

---

Ranks a vector of double precision numbers

— nagm.ht —

---

SUBROUTINE M01DAF (RV, M1, M2, ORDER, IRANK, IFAIL)
INTEGER M1, M2, IRANK(M2), IFAIL
DOUBLE PRECISION RV(M2)
CHARACTER*1 ORDER

Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

M01DAF ranks a vector of double precision numbers in ascending or descending order.

2. Specification
3. Description

M01DAF uses a variant of list-merging, as described by Knuth [1] pp 165-166. The routine takes advantage of natural ordering in the data, and uses a simple list insertion in a preparatory pass to generate ordered lists of length at least 10. The ranking is stable: equal elements preserve their ordering in the input data.

4. References

5. Parameters

1: RV(M2) -- DOUBLE PRECISION array Input
   On entry: elements M1 to M2 of RV must contain double precision values to be ranked.

2: M1 -- INTEGER Input
   On entry: the index of the first element of RV to be ranked.
   Constraint: M1 > 0.

3: M2 -- INTEGER Input
   On entry: the index of the last element of RV to be ranked.
   Constraint: M2 >= M1.

4: ORDER -- CHARACTER*1 Input
   On entry: if ORDER is 'A', the values will be ranked in ascending (i.e., non-decreasing) order; if ORDER is 'D', into descending order. Constraint: ORDER = 'A' or 'D'.

5: IRANK(M2) -- INTEGER array Output
   On exit: elements M1 to M2 of IRANK contain the ranks of the corresponding elements of RV. Note that the ranks are in the range M1 to M2: thus, if RV(i) is the first element in the rank order, IRANK(i) is set to M1.

6: IFAIL -- INTEGER Input/Output
   On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

   On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:
If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL = 1
On entry M2 < 1,
or M1 < 1,
or M1 > M2.

IFAIL = 2
On entry ORDER is not 'A' or 'D'.

7. Accuracy
Not applicable.

8. Further Comments
The average time taken by the routine is approximately proportional to n*\log n, where n = M2 - M1 + 1.

9. Example
The example program reads a list of double precision numbers and ranks them in ascending order.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

Ranks the rows of a matrix of double precision numbers

— nagm.ht —
1. Purpose

M01DEF ranks the rows of a matrix of double precision numbers in ascending or descending order.

2. Specification

```fortran
SUBROUTINE M01DEF (RM, LDM, M1, M2, N1, N2, ORDER, IRANK, IFAIL)
  INTEGER LDM, M1, M2, N1, N2, IRANK(M2), IFAIL
  DOUBLE PRECISION RM(LDM,N2)
  CHARACTER*1 ORDER
```

3. Description

M01DEF ranks rows M1 to M2 of a matrix, using the data in columns N1 to N2 of those rows. The ordering is determined by first ranking the data in column N1, then ranking any tied rows according to the data in column N1 + 1, and so on up to column N2.

M01DEF uses a variant of list-merging, as described by Knuth [1] pp 165-166. The routine takes advantage of natural ordering in the data, and uses a simple list insertion in a preparatory pass to generate ordered lists of length at least 10. The ranking is stable: equal rows preserve their ordering in the input data.

4. References

5. Parameters

1: RM(LDM,N2) -- DOUBLE PRECISION array Input
   On entry: columns N1 to N2 of rows M1 to M2 of RM must contain double precision data to be ranked.
2: LDM -- INTEGER Input
On entry:
the first dimension of the array RM as declared in the
(sub)program from which M01DEF is called.
Constraint: LDM >= M2.

3: M1 -- INTEGER Input
On entry: the index of the first row of RM to be ranked.
Constraint: M1 > 0.

4: M2 -- INTEGER Input
On entry: the index of the last row of RM to be ranked.
Constraint: M2 >= M1.

5: N1 -- INTEGER Input
On entry: the index of the first column of RM to be used.
Constraint: N1 > 0.

6: N2 -- INTEGER Input
On entry: the index of the last column of RM to be used.
Constraint: N2 >= N1.

7: ORDER -- CHARACTER*1 Input
On entry: if ORDER is 'A', the rows will be ranked in
ascending (i.e., non-decreasing) order; if ORDER is 'D',
into descending order. Constraint: ORDER = 'A' or 'D'.

8: IRANK(M2) -- INTEGER array Output
On exit: elements M1 to M2 of IRANK contain the ranks of the
corresponding rows of RM. Note that the ranks are in the
range M1 to M2: thus, if the ith row of RM is the first in
the rank order, IRANK(i) is set to M1.

9: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not
familiar with this parameter (described in the Essential
Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see
Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
On entry M2 < 1,
or \( N2 < 1 \),

or \( M1 < 1 \),

or \( M1 > M2 \),

or \( N1 < 1 \),

or \( N1 > N2 \),

or \( LDM < M2 \).

\textbf{IFAIL= 2}

On entry \texttt{ORDER} is not 'A' or 'D'.

7. Accuracy

Not applicable.

8. Further Comments

The average time taken by the routine is approximately proportional to \( n \log n \), where \( n = M2 - M1 + 1 \).

9. Example

The example program reads a matrix of double precision numbers and ranks the rows in ascending order.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
1. Purpose

M01DJF ranks the columns of a matrix of double precision numbers in ascending or descending order.

2. Specification

```fortran
SUBROUTINE M01DJF (RM, LDM, M1, M2, N1, N2, ORDER, IRANK, IFAIL)
INTEGER LDM, M1, M2, N1, N2, IRANK(N2), IFAIL
DOUBLE PRECISION RM(LDM,N2)
CHARACTER*1 ORDER
```

3. Description

M01DJF ranks columns N1 to N2 of a matrix, using the data in rows M1 to M2 of those columns. The ordering is determined by first ranking the data in row M1, then ranking any tied columns according to the data in row M1 + 1, and so on up to row M2.

M01DJF uses a variant of list-merging, as described by Knuth [1] pp 165-166. The routine takes advantage of natural ordering in the data, and uses a simple list insertion in a preparatory pass to generate ordered lists of length at least 10. The ranking is stable: equal columns preserve their ordering in the input data.

4. References

5. Parameters

1: RM(LDM,N2) -- DOUBLE PRECISION array
   On entry: rows M1 to M2 of columns N1 to N2 of RM must
contain double precision data to be ranked.

2: LDM -- INTEGER Input
On entry:
the first dimension of the array RM as declared in the
(sub)program from which M01DJF is called.
Constraint: LDM >= M2.

3: M1 -- INTEGER Input
On entry: the index of the first row of RM to be used.
Constraint: M1 > 0.

4: M2 -- INTEGER Input
On entry: the index of the last row of RM to be used.
Constraint: M2 >= M1.

5: N1 -- INTEGER Input
On entry: the index of the first column of RM to be ranked.
Constraint: N1 > 0.

6: N2 -- INTEGER Input
On entry: the index of the last column of RM to be ranked.
Constraint: N2 >= N1.

7: ORDER -- CHARACTER*1 Input
On entry: if ORDER is 'A', the columns will be ranked in
ascending (i.e., non-decreasing) order; if ORDER is 'D',
into descending order. Constraint: ORDER = 'A' or 'D'.

8: IRANK(N2) -- INTEGER array Output
On exit: elements N1 to N2 of IRANK contain the ranks of the
 corresponding columns of RM. Note that the ranks are in the
 range N1 to N2: thus, if the ith column of RM is the first
 in the rank order, IRANK(i) is set to N1.

9: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not
familiar with this parameter (described in the Essential
Introduction) the recommended value is 0.
On exit: IFAIL = 0 unless the routine detects an error (see
Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).
CHAPTER 22. NAG LIBRARY ROUTINES

\begin{verbatim}

IFAIL= 1
  On entry M2 < 1,
  or   N2 < 1,
  or   M1 < 1,
  or   M1 > M2,
  or   N1 < 1,
  or   N1 > N2,
  or   LDM < M2.

IFAIL= 2
  On entry ORDER is not 'A' or 'D'.

7. Accuracy

Not applicable.

8. Further Comments

The average time taken by the routine is approximately proportional to n*\log n, where n = N2 - N1 + 1.

9. Example

The example program reads a matrix of double precision numbers and ranks the columns in ascending order.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

\end{verbatim}

\begin{scroll}

\end{scroll}

\end{page}

Rearranges a vector of double precision numbers

— nagm.ht —

\begin{page}{manpageXXm01eaf}{NAG Documentation: m01eaf}

\end{page}
M01EAF rearranges a vector of double precision numbers into the order specified by a vector of ranks.

2. Specification

```
SUBROUTINE M01EAF (RV, M1, M2, IRANK, IFAIL)
    INTEGER M1, M2, IRANK(M2), IFAIL
    DOUBLE PRECISION RV(M2)
```

3. Description

M01EAF is designed to be used typically in conjunction with the M01D- ranking routines. After one of the M01D- routines has been called to determine a vector of ranks, M01EAF can be called to rearrange a vector of real numbers into the rank order. If the vector of ranks has been generated in some other way, then M01ZBF(*) should be called to check its validity before M01EAF is called.

4. References

None.

5. Parameters

1: RV(M2) -- DOUBLE PRECISION array Input/Output
   On entry: elements M1 to M2 of RV must contain double precision values to be rearranged. On exit: these values are rearranged into rank order. For example, if IRANK(i) = M1, then the initial value of RV(i) is moved to RV(M1).
2: M1 -- INTEGER Input

3: M2 -- INTEGER Input
On entry: M1 and M2 must specify the range of the ranks supplied in IRANK and the elements of RV to be rearranged.
Constraint: 0 < M1 <= M2.

4: IRANK(M2) -- INTEGER array Input
On entry: elements M1 to M2 of IRANK must contain a permutation of the integers M1 to M2, which are interpreted as a vector of ranks.

5: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1
On entry M2 < 1,
or M1 < 1,
or M1 > M2.

IFAIL= 2
Elements M1 to M2 of IRANK contain a value outside the range M1 to M2.

IFAIL= 3
Elements M1 to M2 of IRANK contain a repeated value.

If IFAIL = 2 or 3, elements M1 to M2 of IRANK do not contain a permutation of the integers M1 to M2. On exit, the contents of RV may be corrupted. To check the validity of IRANK without the risk of corrupting RV, use M01ZBF(*).

7. Accuracy

Not applicable.
8. Further Comments

The average time taken by the routine is approximately proportional to \( n \), where \( n = M2 - M1 + 1 \).

9. Example

The example program reads a matrix of double precision numbers and rearranges its rows so that the elements of the \( k \)th column are in ascending order. To do this, the program first calls M01DAF to rank the elements of the \( k \)th column, and then calls M01EAF to rearrange each column into the order specified by the ranks. The value of \( k \) is read from the data-file.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

M01ZAF(3NAG)    Foundation Library (12/10/92)    M01ZAF(3NAG)

M01 -- Sorting

M01ZAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose
M01ZAF inverts a permutation, and hence converts a rank vector to an index vector, or vice versa.

2. Specification

SUBROUTINE M01ZAF (IPERM, M1, M2, IFAIL)
INTEGER IPERM(M2), M1, M2, IFAIL

3. Description

There are two common ways of describing a permutation using an integer vector IPERM. The first uses ranks: IPERM(i) holds the position to which the ith data element should be moved in order to sort the data; in other words its rank in the sorted order. The second uses indices: IPERM(i) holds the current position of the data element which would occur in ith position in sorted order. For example, given the values

\begin{align*}
3.5 & \quad 5.9 & \quad 2.9 & \quad 0.5
\end{align*}

to be sorted in ascending order, the ranks would be

\begin{align*}
3 & \quad 4 & \quad 2 & \quad 1
\end{align*}

and the indices would be

\begin{align*}
4 & \quad 3 & \quad 1 & \quad 2
\end{align*}

The M01D- routines generate ranks, and the M01E- routines require ranks to be supplied to specify the re-ordering. However if it is desired simply to refer to the data in sorted order without actually re-ordering them, indices are more convenient than ranks (see the example in Section 9).

M01ZAF can be used to convert ranks to indices, or indices to ranks, as the two permutations are inverses of one another.

4. References

None.

5. Parameters

1: IPERM(M2) -- INTEGER array Input/Output
On entry: elements M1 to M2 of IPERM must contain a permutation of the integers M1 to M2. On exit: these elements contain the inverse permutation of the integers M1 to M2.
2: M1 -- INTEGER  Input

3: M2 -- INTEGER  Input
On entry: M1 and M2 must specify the range of elements used in the array IPERM and the range of values in the permutation, as specified under IPERM. Constraint: 0 < M1 <= M2.

4: IFAIL -- INTEGER  Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1
On entry M2 < 1,

or M1 < 1,

or M1 > M2.

IFAIL= 2
Elements M1 to M2 of IPERM contain a value outside the range M1 to M2.

IFAIL= 3
Elements M1 to M2 of IPERM contain a repeated value.

If IFAIL = 2 or 3, elements M1 to M2 of IPERM do not contain a permutation of the integers M1 to M2; on exit these elements are usually corrupted. To check the validity of a permutation without the risk of corrupting it, use M01ZBF(*).

7. Accuracy

Not applicable.

8. Further Comments

None.

9. Example
The example program reads a matrix of double precision numbers and prints its rows in ascending order as ranked by M01DEF. The program first calls M01DEF to rank the rows, and then calls M01ZAF to convert the rank vector to an index vector, which is used to refer to the rows in sorted order.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

\begin{center}
\textbf{Approximations of Special Functions}
\end{center}

\begin{verbatim}
S(3NAG) Foundation Library (12/10/92) S(3NAG)

S -- Approximations of Special Functions Introduction -- S
Chapter S
Approximations of Special Functions

1. Scope of the Chapter

This chapter is concerned with the provision of some commonly occurring physical and mathematical functions.

2. Background to the Problems

The majority of the routines in this chapter approximate real-valued functions of a single real argument, and the techniques involved are described in Section 2.1. In addition the chapter contains routines for elliptic integrals (see Section 2.2),
Bessel and Airy functions of a complex argument (see Section 2.3), and exponential of a complex argument.

2.1. Functions of a Single Real Argument

Most of the routines for functions of a single real argument have been based on truncated Chebyshev expansions. This method of approximation was adopted as a compromise between the conflicting requirements of efficiency and ease of implementation on many different machine ranges. For details of the reasons behind this choice and the production and testing procedures followed in constructing this chapter see Schonfelder [7].

Basically if the function to be approximated is \( f(x) \), then for \( x \) in \([a,b]\) an approximation of the form

\[
 f(x) = g(x) + C \sum_{r=0}^{\infty} T_r(t)
\]

is used, ( \( > \) denotes, according to the usual convention, a summation in which the first term is halved), where \( g(x) \) is some suitable auxiliary function which extracts any singularities, asymptotes and, if possible, zeros of the function in the range in question and \( t=t(x) \) is a mapping of the general range \([a,b]\) to the specific range \([-1,+1]\) required by the Chebyshev polynomials, \( T_r(t) \). For a detailed description of the properties of the Chebyshev polynomials see Clenshaw [5] and Fox and Parker [6].

The essential property of these polynomials for the purposes of function approximation is that \( T_r(t) \) oscillates between \( \pm 1 \) and it takes its extreme values \( n+1 \) times in the interval \([-1,+1]\). Therefore, provided the coefficients \( C \) decrease in magnitude sufficiently rapidly the error made by truncating the Chebyshev expansion after \( n \) terms is approximately given by

\[
 E(t) \approx C \sum_{r=0}^{n} T_r(t)
\]

That is the error oscillates between \( \pm C \) and takes its extreme value \( n+1 \) times in the interval in question. Now this is just the
condition that the approximation be a mini-max representation, one which minimizes the maximum error. By suitable choice of the interval, \([a,b]\), the auxiliary function, \(g(x)\), and the mapping of the independent variable, \(t(x)\), it is almost always possible to obtain a Chebyshev expansion with rapid convergence and hence truncations that provide near mini-max polynomial approximations to the required function. The difference between the true mini-max polynomial and the truncated Chebyshev expansion is seldom sufficiently great to be of significance.

The evaluation of the Chebyshev expansions follows one of two methods. The first and most efficient, and hence most commonly used, works with the equivalent simple polynomial. The second method, which is used on the few occasions when the first method proves to be unstable, is based directly on the truncated Chebyshev series and uses backward recursion to evaluate the sum. For the first method, a suitably truncated Chebyshev expansion (truncation is chosen so that the error is less than the machine precision) is converted to the equivalent simple polynomial. That is we evaluate the set of coefficients \(b\) such that

\[
y(t) = \sum_{r=0}^{n-1} b_r t^r = \sum_{r=0}^{n-1} b_r T_r(t).
\]

The polynomial can then be evaluated by the efficient Horner’s method of nested multiplications,

\[
y(t) = (b_0 + (b_1 + (b_2 + \ldots (b_{n-2} + b_{n-1})) \ldots)).
\]

This method of evaluation results in efficient routines but for some expansions there is considerable loss of accuracy due to cancellation effects. In these cases the second method is used. It is well known that if

\[
b = \sum_{n=1}^{n-1} b
\]

\[
b = 2tb + \sum_{n=2}^{n-1} b
\]

\[
b = 2tb - b + \sum_{j=n-3}^{0} b
\]

then
and this is always stable. This method is most efficiently implemented by using three variables cyclically and explicitly constructing the recursion.

That is,

\[
\begin{align*}
(\alpha) &= C \\
(\beta) &= 2t(\alpha) + C \\
(\gamma) &= 2t(\beta) - (\alpha) + C \\
(\alpha) &= 2t(\gamma) - (\beta) + C \\
(\beta) &= 2t(\alpha) - (\gamma) + C \\
&\vdots \\
(\alpha) &= 2t(\gamma) - (\beta) + C \\
(\beta) &= 2t(\alpha) - (\gamma) + C
\end{align*}
\]

The auxiliary functions used are normally functions compounded of simple polynomial (usually linear) factors extracting zeros, and the primary compiler-provided functions, sin, cos, ln, exp, sqrt, which extract singularities and/or asymptotes or in some cases basic oscillatory behaviour, leaving a smooth well-behaved function to be approximated by the Chebyshev expansion which can therefore be rapidly convergent.

The mappings of \([a, b]\) to \([-1, +1]\) used, range from simple linear mappings to the case when \(b\) is infinite and considerable improvement in convergence can be obtained by use of a bilinear form of mapping. Another common form of mapping is used when the function is even, that is it involves only even powers in its expansion. In this case an approximation over the whole interval \([-a, a]\) can be provided using a mapping \(t = 2(-)^{-1}\). This embodies the evenness property but the expansion in \(t\) involves all powers and hence removes the necessity of working with an expansion with
half its coefficients zero.

For many of the routines an analysis of the error in principle is given, viz, if $E$ and $(\nabla)$ are the absolute errors in function and argument and $(\epsilon)$ and $(\delta)$ are the corresponding relative errors, then

$$E^\approx = |f'(x)| (\nabla)$$

$$E^\approx = |xf'(x)| (\delta)$$

$$|xf'(x)|$$

$$(\epsilon)^\approx = \frac{|f(x)|}{|f(x)|}$$

If we ignore errors that arise in the argument of the function by propagation of data errors etc and consider only those errors that result from the fact that a real number is being represented in the computer in floating-point form with finite precision, then $(\delta)$ is bounded and this bound is independent of the magnitude of $x$; e.g. on an 11-digit machine

$$|(\delta)| \leq 10^{-11}$$

(This of course implies that the absolute error $(\nabla)$ is also bounded but the bound is now dependent on $x$). However because of this the last two relations above are probably of more interest. If possible the relative error propagation is discussed; that is the behaviour of the error amplification factor $|xf'(x)|/f(x)$ is described, but in some cases, such as near zeros of the function which cannot be extracted explicitly, absolute error in the result is the quantity of significance and here the factor $|xf'(x)|$ is described. In general, testing of the functions has shown that their error behaviour follows fairly well these theoretical error behaviours. In regions, where the error amplification factors are less than or of the order of one, the errors are slightly larger than the above predictions. The errors are here limited largely by the finite precision of arithmetic in the machine but $(\epsilon)$ is normally no more than a few times greater than the bound on $(\delta)$. In regions where the amplification factors are large, order of ten or greater, the theoretical analysis gives a good measure of the accuracy obtainable.

It should be noted that the definitions and notations used for the functions in this chapter are all taken from Abramowitz and Stegun [1]. Users are strongly recommended to consult this book for details before using the routines in this chapter.
22.6. Approximations to Elliptic Integrals

The functions provided here are symmetrised variants of the classic elliptic integrals. These alternative definitions have been suggested by Carlson (see [2], [3] and [4]) and he also developed the basic algorithms used in this chapter.

The standard integral of the first kind is represented by

\[
R(x,y,z) = - \int_{F}^{\infty} \frac{dt}{(t+x)(t+y)(t+z)}
\]

where \(x,y,z \geq 0\) and at most one may be equal to zero.

The normalisation factor, \(-\), is chosen so as to make

\[
R(x,x,x) = \frac{1}{\sqrt{x}}.
\]

If any two of the variables are equal, \(R\) degenerates into the second function

\[
R(x,x,y) = R(x,y,y) = - \int_{C}^{\infty} \frac{dt}{\sqrt{t+x(t+y)}}
\]

where the argument restrictions are now \(x \geq 0\) and \(y \neq 0\).

This function is related to the logarithm or inverse hyperbolic functions if \(0 < y < x\), and to the inverse circular functions if \(0 < x < y\).

The integrals of the second kind are defined by

\[
R(x,y,z) = - \int_{D}^{\infty} \frac{dt}{\sqrt{(t+x)(t+y)(t+z)}}
\]
with $z>0$, $x\geq 0$ and $y\geq 0$ but only one of $x$ or $y$ may be zero.

The function is a degenerate special case of the integral of the third kind

\[
\int_0^\infty \frac{3}{\sqrt{(t+x)(t+y)(t+z)}} \, dt
\]

with $(\rho)\neq 0$, $x, y, z \geq 0$ with at most one equality holding. Thus $R(x, y, z) = R(x, y, z, z)$. The normalisation of both these functions is chosen so that

\[
R(x, x, x) = R(x, x, x, x) = 1/(x\sqrt{x})
\]

The algorithms used for all these functions are based on duplication theorems. These allow a recursion system to be established which constructs a new set of arguments from the old using a combination of arithmetic and geometric means. The value of the function at the original arguments can then be simply related to the value at the new arguments. These recursive reductions are used until the arguments differ from the mean by an amount small enough for a Taylor series about the mean to give sufficient accuracy when retaining terms of order less than six. Each step of the recurrences reduces the difference from the mean by a factor of four, and as the truncation error is of order six, $-n\cdot 4^9$, where $n$ is the number of iterations.

The above forms can be related to the more traditional canonical forms (see Abramowitz and Stegun [1], 17.2).

If we write $q=\cos(\phi)$, $r=1-m\sin(\phi)$, $s=1+n\sin(\phi)$, where $0<\phi\leq -\pi$, we have: the elliptic integral of the first kind:

\[
\int \frac{\sin(\phi)}{\sqrt{1-k^2\sin^2(\phi)}} \, d\phi
\]

\[
F((\phi)|m) = \int_0^1 (1-t^2) (1-mt^2) \, dt = \sin(\phi) \cdot R(q,r,1);
\]

the elliptic integral of the second kind:

\[
E((\phi)|m) = \int_0^1 (1-t^2) (1-mt^2) \, dt = \sin(\phi) \cdot R(q,r,1) - m \cdot \sin(\phi) \cdot R(q,r,1);
\]

the elliptic integral of the third kind:

\[
\Pi(n;(\phi)|m) = \int_0^1 (1-t^2) (1-mt^2) (1+nt^2) \, dt = \sin(\phi) \cdot R(q,r,1) - n \cdot \sin(\phi) \cdot R(q,r,1,1);
\]

Also the complete elliptic integral of the first kind:

\[
K(m) = \int_0^{\pi/2} (1-m\sin^2(\theta)) \, d\theta = R(0,1-m,1);
\]

the complete elliptic integral of the second kind:

\[
E(m) = \int_0^{\pi/2} (1-m\sin^2(\theta)) \, d\theta = R(0,1-m,1) - m \cdot R(0,1-m,1);
\]

2.3. Bessel and Airy Functions of a Complex Argument

The routines for Bessel and Airy functions of a real argument are based on Chebyshev expansions, as described in Section 2.1. The routines for functions of a complex argument, however, use
different methods. These routines relate all functions to the modified Bessel functions $I_{\nu}(z)$ and $K_{\nu}(z)$ computed in the right-half complex plane, including their analytic continuations. $I_{\nu}$ and $K_{\nu}$ are computed by different methods according to the values of $z$ and $\nu$. The methods include power series, asymptotic expansions and Wronskian evaluations. The relations between functions are based on well known formulae (see Abramowitz and Stegun [1]).

2.4. References

3. Recommendations on Choice and Use of Routines

3.1. Elliptic Integrals

IMPORTANT ADVICE: users who encounter elliptic integrals in the course of their work are strongly recommended to look at transforming their analysis directly to one of the Carlson forms, rather than the traditional canonical Legendre forms. In general, the extra symmetry of the Carlson forms is likely to simplify the analysis, and these symmetric forms are much more stable to calculate.

The routine S21BAF for $\mathbf{R}$ is largely included as an auxiliary to the other routines for elliptic integrals. This integral
essentially calculates elementary functions, e.g.

\[
\frac{(1+x)^2}{x-1} = x \ln(x) + (x-1), \quad x > 0;
\]

\[
\text{C}(\frac{2}{1-x}, 1), \quad |x| \leq 1;
\]

2
\[
\text{arcsinx} = x \ln(1-x, 1), \quad |x| \leq 1;
\]

2
\[
\text{arcsinhx} = x \ln(1+x, 1), \quad \text{etc}
\]

In general this method of calculating these elementary functions is not recommended as there are usually much more efficient specific routines available in the Library. However, S21BAF may be used, for example, to compute \(\ln(x)/(x-1)\) when \(x\) is close to 1, without the loss of significant figures that occurs when \(\ln(x)\) and \(x-1\) are computed separately.

3.2. Bessel and Airy Functions

For computing the Bessel functions \(J_\nu(x), Y_\nu(x), I_\nu(x)\) and \(K_\nu(x)\) where \(x\) is real and \(\nu = 0\) or 1, special routines are provided, which are much faster than the more general routines that allow a complex argument and arbitrary real \(\nu \geq 0\) functions and their derivatives \(\text{Ai}(x), \text{Bi}(x), \text{Ai}'(x), \text{Bi}'(x)\) for a real argument which are much faster than the routines for complex arguments.

CHAPTER 22. NAG LIBRARY ROUTINES

2. Specification

COMPLEX(KIND(1.0D0)) FUNCTION S01EAF (Z, IFAIL)
INTEGER IFAIL
COMPLEX(KIND(1.0D0)) Z

3. Description

This routine evaluates the exponential function $e^z$, taking care to avoid machine overflow, and giving a warning if the result cannot be computed to more than half precision. The function is evaluated as $e^z = e^x \cos y + i e^x \sin y$, where $x$ and $y$ are the real and imaginary parts respectively of $z$.

Since $\cos y$ and $\sin y$ are less than or equal to 1 in magnitude, it is possible that $e^x \cos y$ may overflow although $e^x \sin y$ does not. In this case the alternative formula $\text{sign} \cos y e^{x+\ln|\cos y|}$ is used for the real part of the result, and $\text{sign} \sin y e^{x+\ln|\sin y|}$ for the imaginary part. If either part of the result still overflows, a warning is returned through parameter IFAIL.

If $\text{Im} z$ is too large, precision may be lost in the evaluation of $\sin y$ and $\cos y$. Again, a warning is returned through IFAIL.

4. References

None.

5. Parameters

1: Z -- COMPLEX(KIND(1.0D0)) Input
   On entry: the argument $z$ of the function.

2: IFAIL -- INTEGER Input/Output
   On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

   On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:
IFAIL= 1
The real part of the result overflows, and is set to the largest safe number with the correct sign. The imaginary part of the result is meaningful.

IFAIL= 2
The imaginary part of the result overflows, and is set to the largest safe number with the correct sign. The real part of the result is meaningful.

IFAIL= 3
Both real and imaginary parts of the result overflow, and are set to the largest safe number with the correct signs.

IFAIL= 4
The computed result is accurate to less than half precision, due to the size of Im z.

IFAIL= 5
The computed result has no precision, due to the size of Im z, and is set to zero.

7. Accuracy

Accuracy is limited in general only by the accuracy of the Fortran intrinsic functions in the computation of \( \sin y \), \( \cos y \) and \( x e \), where \( x=\text{Re } z \), \( y=\text{Im } z \). As \( y \) gets larger, precision will probably be lost due to argument reduction in the evaluation of the sine and cosine functions, until the warning error IFAIL = 4 occurs when \( y \) gets larger than \( \sqrt{1}/(\text{epsilon}) \), where (epsilon) is the machine precision. Note that on some machines, the intrinsic functions \( \sin \) and \( \cos \) will not operate on arguments larger than about \( \sqrt{1}/(\text{epsilon}) \), and so IFAIL can never return as 4.

In the comparatively rare event that the result is computed by \( x+\ln|\cos y| \) and \( x+\ln|\sin y| \), a further small loss of accuracy may be expected due to rounding errors in the logarithmic function.

8. Further Comments

None.
9. Example

The example program reads values of the argument z from a file, evaluates the function at each value of z and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

Returns the value of the exponential integral \( E(x) \)

S13 -- Approximations of Special Functions      S13AAF
S13AAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S13AAF returns the value of the exponential integral \( E(x) \), via the routine name.

2. Specification

\begin{verbatim}
DOUBLE PRECISION FUNCTION S13AAF (X, IFAIL)
INTEGER IFAIL
\end{verbatim}
DOUBLE PRECISION X

3. Description

The routine calculates an approximate value for

\[ E(x) = \frac{\infty}{e^{-u}} \]

\[ = \frac{1}{x} \int_0^\infty \frac{du}{e^u}, \quad x > 0. \]

For \( 0 < x \leq 4 \), the approximation is based on the Chebyshev expansion

\[ E(x) = y(t) - \ln x = \sum_{r=0}^{1} a_r T_r(t) - \ln x, \quad \text{where} \quad t = -x - 1. \]

For \( x > 4 \),

\[ E(x) = \frac{1}{x^r} y(t) = \sum_{r=0}^{1} a_r T_r(t), \quad \text{where} \quad t = -1.0 + 14.5/(x + 3.25) = \frac{11.25 - x}{3.25 + x}. \]

In both cases, \(-1 \leq t \leq +1\).

To guard against producing underflows, if \( x > x_{\text{hi}} \) the result is set directly to zero. For the value \( x \) see the Users’ Note for your implementation.

4. References

5. Parameters

1: X -- DOUBLE PRECISION
Input
On entry: the argument \( x \) of the function. Constraint: \( X > 0 \).
2: IFAIL -- INTEGER Input/Output

Before entry, IFAIL must be assigned a value. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

Unless the routine detects an error (see Section 6), IFAIL contains 0 on exit.

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
The routine has been called with an argument less than or equal to zero for which the function is not defined. The result returned is zero.

7. Accuracy

If (delta) and (epsilon) are the relative errors in argument and result respectively, then in principle,

\[ \frac{|-x|}{|E(x)|} \approx \frac{|(epsilon)|}{E(x)} \cdot (delta) \]

so the relative error in the argument is amplified in the result \(-x\) by at least a factor \(e / E(x)\). The equality should hold if (delta) is greater than the machine precision ((delta) due to data errors etc) but if (delta) is simply a result of round-off in the machine representation, it is possible that an extra figure may be lost in internal calculation and round-off.

The behaviour of this amplification factor is shown in Figure 1.

---

Figure 1
Please see figure in printed Reference Manual

It should be noted that, for small \(x\), the amplification factor tends to zero and eventually the error in the result will be limited by machine precision.

For large \(x\),

\[ (epsilon)^{-x}(delta) = (Delta), \]
the absolute error in the argument.

8. Further Comments

None.

9. Example

The example program reads values of the argument $x$ from a file, evaluates the function at each value of $x$ and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

\end{verbatim}

\end{page}

---

Returns the value of the cosine integral

— nags.ht —

\begin{page}{manpageXXs13acf}{NAG Documentation: s13acf}
\beginscroll
\begin{verbatim}
S13ACF(3NAG) Foundation Library (12/10/92) S13ACF(3NAG)

S13 -- Approximations of Special Functions
S13ACF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S13ACF returns the value of the cosine integral
\[ \text{Ci}(x) = (\gamma) + \ln x + \int_{u=0}^{x} \frac{\cos^{-1} u}{u} \, du, \quad x > 0 \]

via the routine name, where \((\gamma)\) denotes Euler’s constant.

2. Specification

\[
\text{DOUBLE PRECISION FUNCTION S13ACF (X, IFAIL)}
\]

\[
\text{INTEGER IFAIL}
\]

\[
\text{DOUBLE PRECISION X}
\]

3. Description

The routine calculates an approximate value for \(\text{Ci}(x)\).

For \(0 < x \leq 16\) it is based on the Chebyshev expansion

\[
\frac{(x)^2}{\text{Ci}(x)} = \ln x + \sum_{r=0}^{\infty} a_r \text{T}_r(\cos^{-1} x) - 1.
\]

For \(16 < x < \text{hi}\) where the value of \(x\) is given in the Users’ Note for your implementation,

\[
\frac{f(x)\sin x}{x^2} \quad \frac{g(x)\cos x}{x}
\]

\[
\text{Ci}(x) = \sum_{r=0}^{\infty} f_r \text{T}_r(\cos^{-1} x) \quad \sum_{r=0}^{\infty} g_r \text{T}_r(\cos^{-1} x) - 1.
\]

For \(x \geq \text{hi}\), \(\text{Ci}(x) = 0\) to within the accuracy possible (see Section 7).

4. References

5. Parameters
1: X -- DOUBLE PRECISION  
   Input
   On entry: the argument x of the function. Constraint: X > 0.

2: IFAIL -- INTEGER  
   Input/Output
   On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
   On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
   The routine has been called with an argument less than or equal to zero for which the function is not defined. The result returned is zero.

7. Accuracy

If E and (epsilon) are the absolute and relative errors in the result and (delta) is the relative error in the argument then in principle these are related by

\[
| \frac{(\delta)\cos x}{E} | \sim |(\delta)\cos x| \quad \text{and} \quad |(\epsilon)| \sim \frac{|(\delta)\cos x|}{|\text{Ci}(x)|}.
\]

That is accuracy will be limited by machine precision near the origin and near the zeros of \( \cos x \), but near the zeros of \( \text{Ci}(x) \) only absolute accuracy can be maintained.

The behaviour of this amplification is shown in Figure 1.

\[
\frac{\sin x}{x}
\]

For large values of x, \( Ci(x) \sim \frac{x}{\sin x} \) therefore

\[
(\epsilon) \sim (\delta)xcotx \quad \text{and} \quad (\delta) \text{is limited by the finite precision of the machine it becomes impossible to return results which have any relative accuracy. That is, when } x \geq 1/(\delta) \text{ we have that } |Ci(x)| \leq E \text{ and hence is not significantly different from zero.}
\]
Hence \( x \) is chosen such that for values of \( x \gg x^* \), \( C_i(x) \) in principle would have values less than the machine precision and so is essentially zero.

8. Further Comments

For details of the time taken by the routine see the Users’ Note for your implementation.

9. Example

The example program reads values of the argument \( x \) from a file, evaluates the function at each value of \( x \) and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
1. Purpose

S13ADF returns the value of the sine integral

\[
Si(x) = \int_{0}^{x} \frac{\sin u}{u} \, du
\]

via the routine name.

2. Specification

DOUBLE PRECISION FUNCTION S13ADF (X, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X

3. Description

The routine calculates an approximate value for Si(x).

For |x|<=16.0 it is based on the Chebyshev expansion

\[
Si(x) = x - \sum_{r=0}^{\infty} a_r T_r(\frac{x}{16})
\]

where \(a_r\) are constants.

For 16<|x|<x , where x is an implementation dependent number,

\[
Si(x) = \text{sign}(x) \left\{ \frac{\pi}{2} \left[ \frac{f(x)}{x} \cos x - g(x) \sin x \right] \right\}
\]

where \(f(x) = > f T(t)\) and \(g(x) = > g T(t)\), t=2( --) -1.

For |x|>=x , Si(x) = -(\pi)signx to within machine precision.

4. References

5. Parameters

1: X -- DOUBLE PRECISION  
   Input
   On entry: the argument x of the function.

2: IFAIL -- INTEGER  
   Input/Output
   On entry: IFAIL must be set to 0, -1 or 1. For users not
   familiar with this parameter (described in the Essential
   Introduction) the recommended value is 0.
   
   On exit: IFAIL = 0 unless the routine detects an error (see
   Section 6).

6. Error Indicators and Warnings

There are no failure exits from this routine. The parameter IFAIL
has been included for consistency with other routines in this
chapter.

7. Accuracy

If (delta) and (epsilon) are the relative errors in the argument
and result, respectively, then in principle

\[
\frac{|(delta)| \sin x|}{\frac{1}{Si(x)}} \approx \frac{1}{\epsilon}.
\]

The equality may hold if (delta) is greater than the machine
precision ((delta) due to data errors etc) but if (delta) is
simply due to round-off in the machine representation, then since
the factor relating (delta) to (epsilon) is always less than one,
the accuracy will be limited by machine precision.

8. Further Comments

For details of the time taken by the routine see the Users’ Note
for your implementation.

9. Example

The example program reads values of the argument x from a file,
evaluates the function at each value of x and prints the results.

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.
Returns the value of the Gamma function

— nags.ht —

S14AAF(3NAG) Foundation Library (12/10/92) S14AAF(3NAG)

S14 -- Approximations of Special Functions
S14AAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S14AAF returns the value of the Gamma function \((\Gamma)(x)\), via the routine name.

2. Specification

```c
DOUBLE PRECISION FUNCTION S14AAF (X, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X
```

3. Description

This routine evaluates an approximation to the Gamma function \((\Gamma)(x)\). The routine is based on the Chebyshev expansion:

\[
(\Gamma)(1+u) = \sum_{r=0}^{\infty} a_r T_r(t), \quad \text{where } 0 \leq u < 1, \quad t = 2u - 1,
\]

where \(T_r(t)\) are Chebyshev polynomials of the first kind.
and uses the property \((\Gamma)(1+x) = x(\Gamma)(x)\). If \(x = N + 1 + u\) where \(N\) is integral and \(0 \leq u < 1\) then it follows that:

\[
\begin{align*}
\text{for } N > 0 & \quad (\Gamma)(x) = (x-1)(x-2)\ldots(x-N)(\Gamma)(1+u), \\
\text{for } N = 0 & \quad (\Gamma)(x) = (\Gamma)(1+u), \\
\text{for } N < 0 & \quad (\Gamma)(x) = \frac{(\Gamma)(1+u)}{x(x+1)(x+2)\ldots(x-N-1)}.
\end{align*}
\]

There are four possible failures for this routine:

(i) if \(x\) is too large, there is a danger of overflow since \((\Gamma)(x)\) could become too large to be represented in the machine;

(ii) if \(x\) is too large and negative, there is a danger of underflow;

(iii) if \(x\) is equal to a negative integer, \((\Gamma)(x)\) would overflow since it has poles at such points;

(iv) if \(x\) is too near zero, there is again the danger of overflow on some machines. For small \(x\), \((\Gamma)(x)\approx \frac{1}{x}\), and on some machines there exists a range of non-zero but small values of \(x\) for which \(1/x\) is larger than the greatest representable value.

4. References

5. Parameters

1: \(X\) -- DOUBLE PRECISION Input
On entry: the argument \(x\) of the function. Constraint: \(X\) must not be a negative integer.

2: \(IFAIL\) -- INTEGER Input/Output
On entry: \(IFAIL\) must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: \(IFAIL = 0\) unless the routine detects an error (see Section 6).
6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
The argument is too large. On soft failure the routine returns the approximate value of (Gamma)(x) at the nearest valid argument.

IFAIL= 2
The argument is too large and negative. On soft failure the routine returns zero.

IFAIL= 3
The argument is too close to zero. On soft failure the routine returns the approximate value of (Gamma)(x) at the nearest valid argument.

IFAIL= 4
The argument is a negative integer, at which value (Gamma)(x) is infinite. On soft failure the routine returns a large positive value.

7. Accuracy

Let (delta) and (epsilon) be the relative errors in the argument and the result respectively. If (delta) is somewhat larger than the machine precision (i.e., is due to data errors etc), then (epsilon) and (delta) are approximately related by:

(epsilon)\approx |x(\Psi)(x)| (delta)

(provided (epsilon) is also greater than the representation error). Here (\Psi)(x) is the digamma function (Gamma)'(x) (Gamma)(x)

Figure 1 shows the behaviour of the error amplification factor |x(\Psi)(x)|.

Figure 1
Please see figure in printed Reference Manual

If (delta) is of the same order as machine precision, then rounding errors could make (epsilon) slightly larger than the above relation predicts.

There is clearly a severe, but unavoidable, loss of accuracy for arguments close to the poles of (Gamma)(x) at negative integers.
However relative accuracy is preserved near the pole at $x=0$ right up to the point of failure arising from the danger of overflow.

Also accuracy will necessarily be lost as $x$ becomes large since in this region

$$(\varepsilon) = (\delta) x \ln x.$$

However since $(\Gamma)(x)$ increases rapidly with $x$, the routine must fail due to the danger of overflow before this loss of accuracy is too great. (e.g. for $x=20$, the amplification factor $\approx 60$.)

8. Further Comments

For details of the time taken by the routine see the Users’ Note for your implementation.

9. Example

The example program reads values of the argument $x$ from a file, evaluates the function at each value of $x$ and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

---

Returns a value for the logarithm of the Gamma function

— nags.ht —

S14ABF(3NAG)  Foundation Library (12/10/92)  S14ABF(3NAG)
1. Purpose

S14ABF returns a value for the logarithm of the Gamma function, \( \ln(\Gamma(x)) \), via the routine name.

2. Specification

```fortran
DOUBLE PRECISION FUNCTION S14ABF (X, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X
```

3. Description

This routine evaluates an approximation to the logarithm of the Gamma function, \( \ln(\Gamma(x)) \). It is based on two Chebyshev expansions.

For \( 0 < x \leq x_{\text{small}} \), \( \ln(\Gamma(x)) = -\ln(x) \) to within machine accuracy.

For \( x_{\text{small}} < x \leq 15.0 \), the recursive relation

\[ (\Gamma)(1+x) = x(\Gamma)(x) \]

is used to reduce the calculation to one involving \( (\Gamma)(1+u) \), \( 0 \leq u < 1 \) which is evaluated as:

\[
(\Gamma)(1+u) = \sum_{r=0}^{\infty} a_r T_r(t), \quad t = 2u - 1.
\]

Once \( (\Gamma)(x) \) has been calculated, the required result is produced by taking the logarithm.

For \( 15.0 < x \leq x_{\text{big}} \),

\[
\ln(\Gamma(x)) = (x - 1)\ln(x) - \frac{1}{2}\ln(2\pi) + y(x)/x
\]

where

\[
y(x) = \sum_{r=0}^{\infty} b_r T_r(t), \quad t = 2 - 2(\cdots) - 1.
\]

The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.
r=0

For \( x < x \leq x \) the term \( y(x)/x \) is negligible and so its calculation is omitted.

For \( x > x \) there is a danger of setting overflow so the routine must fail.

For \( x \leq 0.0 \) the function is not defined and the routine fails.

Note: \( x \) is calculated so that if \( x < x \), \((\Gamma)(x)=1/x\) to small within machine accuracy. \( x \) is calculated so that if \( x > x \),

\[
\ln(\Gamma)(x) = (x-1)\ln x - x + \frac{1}{2}\ln 2\pi
\]

to within machine accuracy. \( x \) is calculated so that \( \ln(\Gamma)(x) \) is close to the value returned by X02ALF(*).

4. References

5. Parameters

1: \( X \) -- DOUBLE PRECISION
   Input
   On entry: the argument \( x \) of the function. Constraint: \( X > 0.0 \).

2: \( IFAIL \) -- INTEGER
   Input/Output
   On entry: \( IFAIL \) must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

   On exit: \( IFAIL = 0 \) unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

\( IFAIL = 1 \)
X <= 0.0, the function is undefined. On soft failure, the routine returns zero.

IFAIL= 2
X is too large, the function would overflow. On soft failure, the routine returns the value of the function at the largest permissible argument.

7. Accuracy

Let (delta) and (epsilon) be the relative errors in the argument and result respectively, and E be the absolute error in the result.

If (delta) is somewhat larger than the relative machine precision, then

\[
E \approx \left| \frac{x \Psi(x)}{\ln(\Gamma(x))} \right| (\text{epsilon}) \approx \left| \frac{x \Psi(x)}{\ln(\Gamma(x))} \right| (\text{delta})
\]

where (Psi)(x) is the digamma function \[ \frac{(\Gamma)'(x)}{\Gamma(x)} \]

Figure 1 and Figure 2 show the behaviour of these error amplification factors.

Figure 1
Please see figure in printed Reference Manual

Figure 2
Please see figure in printed Reference Manual

These show that relative error can be controlled, since except near x=1 or 2 relative error is attenuated by the function or at least is not greatly amplified.

For large x, (epsilon) \approx (1 + \frac{1}{\ln x}) (delta) and for small x,

( 1 )

For large x, (epsilon) \approx (1 + \frac{1}{\ln x}) (delta) and for small x,

( 1 )

The function ln(\Gamma(x)) has zeros at x=1 and 2 and hence relative accuracy is not maintainable near those points. However absolute accuracy can still be provided near those zeros as is shown above.

If however, (delta) is of the order of the machine precision,
then rounding errors in the routine’s internal arithmetic may result in errors which are slightly larger than those predicted by the equalities. It should be noted that even in areas where strong attenuation of errors is predicted the relative precision is bounded by the effective machine precision.

8. Further Comments

For details of the time taken by the routine see the Users’ Note for your implementation.

9. Example

The example program reads values of the argument x from a file, evaluates the function at each value of x and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

---

Incomplete gamma functions $P(a,x)$ and $Q(a,x)$

--- nags.ht ---

Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.
1. Purpose

S14BAF computes values for the incomplete gamma functions $P(a,x)$ and $Q(a,x)$.

2. Specification

```fortran
SUBROUTINE S14BAF (A, X, TOL, P, Q, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION A, X, TOL, P, Q
```

3. Description

This subroutine evaluates the incomplete gamma functions in the normalised form

$$
P(a,x) = \frac{1}{(\Gamma(a))} \int_{0}^{\infty} t^{1/a - 1} e^{-t} dt,
$$

$$
Q(a,x) = \frac{1}{(\Gamma(a))} \int_{x}^{\infty} t^{1/a - 1} e^{-t} dt,
$$

with $x \geq 0$ and $a > 0$, to a user-specified accuracy. With this normalisation, $P(a,x) + Q(a,x) = 1$.

Several methods are used to evaluate the functions depending on the arguments $a$ and $x$, the methods including Taylor expansion for $P(a,x)$, Legendre's continued fraction for $Q(a,x)$, and power series for $Q(a,x)$. When both $a$ and $x$ are large, and $a \approx x$, the uniform asymptotic expansion of Temme [3] is employed for greater efficiency - specifically, this expansion is used when $a \geq 20$ and $0.7a \leq x \leq 1.4a$.

Once either of $P$ or $Q$ is computed, the other is obtained by subtraction from 1. In order to avoid loss of relative precision in this subtraction, the smaller of $P$ and $Q$ is computed first.

This routine is derived from subroutine GAM in Gautschi [2].

4. References

5. Parameters

1: A -- DOUBLE PRECISION Input
   On entry: the argument a of the functions. Constraint: A > 0.0.

2: X -- DOUBLE PRECISION Input
   On entry: the argument x of the functions. Constraint: X >= 0.0.

3: TOL -- DOUBLE PRECISION Input
   On entry: the relative accuracy required by the user in the results. If S14BAF is entered with TOL greater than 1.0 or less than machine precision, then the value of machine precision is used instead.

4: P -- DOUBLE PRECISION Output

5: Q -- DOUBLE PRECISION Output
   On exit: the values of the functions P(a,x) and Q(a,x) respectively.

6: IFAIL -- INTEGER Input/Output
   On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

   On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
   On entry A <= 0.0.

IFAIL= 2
   On entry X < 0.0.

IFAIL= 3
Convergence of the Taylor series or Legendre continued fraction fails within 600 iterations. This error is extremely unlikely to occur; if it does, contact NAG.

7. Accuracy

There are rare occasions when the relative accuracy attained is somewhat less than that specified by parameter TOL. However, the error should never exceed more than one or two decimal places. Note also that there is a limit of 18 decimal places on the achievable accuracy, because constants in the routine are given to this precision.

8. Further Comments

The time taken for a call of S14BAF depends on the precision requested through TOL, and also varies slightly with the input arguments a and x.

9. Example

The example program reads values of the argument a and x from a file, evaluates the function and prints the results. The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

---

Returns the value of the complementary error function
S15 -- Approximations of Special Functions
S15ADF
S15ADF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S15ADF returns the value of the complementary error function, erfcx, via the routine name.

2. Specification

    DOUBLE PRECISION FUNCTION S15ADF (X, IFAIL)
    INTEGER IFAIL
    DOUBLE PRECISION X

3. Description

The routine calculates an approximate value for the complement of the error function

\[
\text{erfc } x = \frac{2}{\sqrt{\pi}} \int_u^\infty e^{-u^2} \, du = 1 - \text{erf } x.
\]

For \( x \geq 0 \), it is based on the Chebyshev expansion

\[
\text{erfc } x = e^{-x} \sum_{r=0}^{\infty} a_r T_r(t),
\]

where \( y(x) = > a T(t) \) and \( t = (x - 3.75)/(x + 3.75) \), \(-1 \leq t \leq +1\). For \( x \geq x_h \), where there is a danger of setting underflow, the result is returned as zero.

For \( x < 0 \), \( \text{erfc } x = 2 - e^{-x} y(|x|) \).
For \( x < x < 0 \), the result is returned as 2.0 which is correct to low within machine precision. The values of \( x \) and \( x \) are given in the Users' Note for your implementation.

4. References

5. Parameters

1: \( X \) -- DOUBLE PRECISION 
   Input
   On entry: the argument \( x \) of the function.

2: \( IFAIL \) -- INTEGER 
   Input/Output
   On entry: \( IFAIL \) must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
   On exit: \( IFAIL = 0 \) unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

There are no failure exits from this routine. The parameter \( IFAIL \) has been included for consistency with other routines in this chapter.

7. Accuracy

If (\( \delta \)) and (\( \varepsilon \)) are relative errors in the argument and result, respectively, then in principle

\[
\frac{2}{\pi} \text{erfc} x
\]

That is, the relative error in the argument, \( x \), is amplified by a factor \( \frac{2}{\pi} \text{erfc} x \) in the result.
\( \sqrt{\pi} \text{erfc} \ x \)

The behaviour of this factor is shown in Figure 1.

Figure 1

Please see figure in printed Reference Manual

It should be noted that near \( x=0 \) this factor behaves as \(-\frac{2x}{\sqrt{\pi}}\)

and hence the accuracy is largely determined by the machine precision. Also for large negative \( x \), where the factor is

\[ \frac{2}{\sqrt{\pi}} \]

\( xe \)

\(-\frac{2x}{\sqrt{\pi}}\), accuracy is mainly limited by machine precision.

\( \sqrt{\pi} \)

However, for large positive \( x \), the factor becomes \(-\frac{2x}{\sqrt{\pi}}\) and to an extent relative accuracy is necessarily lost. The absolute accuracy \( E \) is given by

\[ \frac{2}{\sqrt{\pi}} \frac{2xe}{\delta} \]

so absolute accuracy is guaranteed for all \( x \).

8. Further Comments

For details of the time taken by the routine see the Users’ Note for your implementation.

9. Example

The example program reads values of the argument \( x \) from a file, evaluates the function at each value of \( x \) and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation.
Library software and should be available on-line.

Returns the value of the error function \( \text{erfx} \)

**— nags.ht —**

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. **Purpose**

   \text{S15AEF} \text{returns the value of the error function \( \text{erfx} \), via the routine name.}

2. **Specification**

   \text{DOUBLE PRECISION FUNCTION S15AEF (X, IFAIL)}
   \text{INTEGER IFAIL}
   \text{DOUBLE PRECISION X}

3. **Description**

   Evaluates the error function,
   \[
   \frac{2}{2} x - t \quad 2 \quad / 
   \]
erf \( x \) = \frac{1}{\sqrt{\pi}} \int_{0}^{\infty} e^{-t^2} dt.

For \( |x| \leq 2 \),
\[
\text{erf} \ x = x > a \ T (t), \text{ where } t = -x - \frac{1}{2},
\]
\[r = 0\]

For \( 2 < |x| < x \),
\[
\text{erf} \ x = \text{sign} x \left( 1 - \frac{e^{-x^2}}{\sqrt{\pi} \ r r} \right) \text{ for } x + 3
\]
\[
\text{erf} \ x = \text{sign} x \left( 1 - \frac{e^{-x^2}}{\sqrt{\pi} \ r r} \right) \text{ for } x + 3
\]

For \( |x| \geq x \),
\[
\text{erf} \ x = \text{sign} x.
\]

\( x \) is the value above which erf \( x \approx -1 \) within machine precision.

4. References

5. Parameters

1: \( X \) -- DOUBLE PRECISION
   Input on entry: the argument \( x \) of the function.

2: IFAIL -- INTEGER
   Input/Output
   On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

   On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

There are no failure exits from this routine. The parameter IFAIL has been included for consistency with other routines in this chapter.
7. Accuracy

On a machine with approximately 11 significant figures the routine agrees with available tables to 10 figures and consistency checking with S15ADF of the relation

\[ \text{erf } x + \text{erfc } x = 1.0 \]

shows errors in at worst the 11th figure.

8. Further Comments

None.

9. Example

The example program reads values of the argument \( x \) from a file, evaluates the function at each value of \( x \) and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

---

Returns the value of the Bessel Function \( Y_0(x) \)

— nags.ht —
CHAPTER 22. NAG LIBRARY ROUTINES

Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S17ACF returns the value of the Bessel Function $Y(x)$, via the routine name.

2. Specification

```plaintext
DOUBLE PRECISION FUNCTION S17ACF (X, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X
```

3. Description

This routine evaluates an approximation to the Bessel Function of the second kind $Y(x)$.

Note: $Y(x)$ is undefined for $x\leq 0$ and the routine will fail for such arguments.

The routine is based on four Chebyshev expansions:

For $0<x=8$,

$$
Y(x) = \frac{\ln x}{2} - \sum_{r=0}^{\infty} \frac{a_r T_r(t)}{r!} + \sum_{r=0}^{\infty} \frac{b_r T_r(t)}{r!},
$$

where $t = \frac{2}{\pi} x - 1$.

For $x>8$,

$$
Y(x) = \frac{1}{x^2} \left\{ \frac{P(x) \sin(x) + Q(x) \cos(x)}{\pi^2} \right\},
$$

where $P(x) = \sum_{r=0}^{\infty} c_r T_r(t)$.

Note: $P(x)$ is undefined for $x=0$ and the routine will fail for such arguments.
and \( Q(x) = - \sum_{r=0}^{2} \frac{d}{dx} T_r(x) \), with \( t=2(-) -1 \).

For \( x \) near zero, \( Y(x) \approx \frac{-\ln(-1)}{(\pi)(2)} + \gamma \), where \( \gamma \) denotes Euler's constant. This approximation is used when \( x \) is sufficiently small for the result to be correct to machine precision.

For very large \( x \), it becomes impossible to provide results with any reasonable accuracy (see Section 7), hence the routine fails. Such arguments contain insufficient information to determine the phase of oscillation of \( Y(x) \); only the amplitude, \( \sqrt{x} \), can be determined and this is returned on soft failure. The range for which this occurs is roughly related to the machine precision: the routine will fail if \( x > 1/\text{machine precision} \) (see the Users' Note for your implementation for details).

4. References

5. Parameters

1: \( X \) \hspace{1cm} DOUBLE PRECISION \hspace{1cm} Input
   On entry: the argument \( x \) of the function. Constraint: \( X > 0 \).

2: \( IFAIL \) \hspace{1cm} INTEGER \hspace{1cm} Input/Output
   On entry: \( IFAIL \) must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

   On exit: \( IFAIL = 0 \) unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:
IFAIL= 1
   X is too large. On soft failure the routine returns the
   amplitude of the Y oscillation, \( \sqrt{2/(\pi)x} \).

IFAIL= 2
   X <= 0.0, Y is undefined. On soft failure the routine
   returns zero.

7. Accuracy

Let \( (\delta) \) be the relative error in the argument and \( E \) be the
absolute error in the result. (Since \( Y(x) \) oscillates about zero,
absolute error and not relative error is significant, except for
very small \( x \).)

If \( (\delta) \) is somewhat larger than the machine representation
error (e.g. if \( (\delta) \) is due to data errors etc), then \( E \) and
\( (\delta) \) are approximately related by

\[
E \approx |xY(x)|(\delta)
\]

(provided \( E \) is also within machine bounds). Figure 1 displays the
behaviour of the amplification factor \( |xY(x)| \).

Figure 1
Please see figure in printed Reference Manual

However, if \( (\delta) \) is of the same order as the machine
representation errors, then rounding errors could make \( E \) slightly
larger than the above relation predicts.

For very small \( x \), the errors are essentially independent of
\( (\delta) \) and the routine should provide relative accuracy bounded
by the machine precision.

For very large \( x \), the above relation ceases to apply. In this

\[
/ 2 \ ( (\pi)) / 2
\]
\[
region, Y (x)^{\sim} \ / \ -----\sin(x- ----). The amplitude / -----
0 \ \sqrt{ (\pi)x \ ( 4 ) } \ / (\pi)x
\]
can be calculated with reasonable accuracy for all \( x \), but
\[
( (\pi)) \ (\pi)
\]
sin(\( x- ---- \) cannot. If \( x- ---- \) is written as 2N(\( \pi \))+(\thetaeta)
22.6. **NAGS.HT**

\[
\sin(x - \frac{(4\pi)}{4})
\]

where \( N \) is an integer and \( 0 \leq (\theta) < 2(\pi) \), then \( \sin(x - \frac{(4\pi)}{4}) \) is determined by \( (\theta) \) only. If \( x > \Delta \), \( (\theta) \) cannot be determined with any accuracy at all. Thus if \( x \) is greater than, or of the order of the inverse of machine precision, it is impossible to calculate the phase of \( Y_0(x) \) and the routine must fail.

8. Further Comments

For details of the time taken by the routine see the Users’ Note for your implementation.

9. Example

The example program reads values of the argument \( x \) from a file, evaluates the function at each value of \( x \) and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
S17ADF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S17ADF returns the value of the Bessel Function \( Y(x) \), via the routine name.

2. Specification

```fortran
DOUBLE PRECISION FUNCTION S17ADF (X, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X
```

3. Description

This routine evaluates an approximation to the Bessel Function of the second kind \( Y(x) \).

Note: \( Y(x) \) is undefined for \( x \leq 0 \) and the routine will fail for such arguments.

The routine is based on four Chebyshev expansions:

For \( 0 < x \leq 8 \),

\[
Y(x) = \sum_{r=0}^{2} \left( \frac{2}{(\pi)^{r}} \right) a_{r} T_{r}(t) - \sum_{r=0}^{2} \left( \frac{2}{(\pi)^{r}} \right) b_{r} T_{r}(t), \quad \text{with } t = \frac{1}{x} - \frac{1}{8}
\]

For \( x > 8 \),

\[
Y(x) = \frac{1}{\sqrt{x}} \left\{ \sum_{r=0}^{2} \left( \frac{2}{(\pi)^{r}} \right) a_{r} T_{r}(u) - \sum_{r=0}^{2} \left( \frac{2}{(\pi)^{r}} \right) b_{r} T_{r}(u) \right\}, \quad \text{with } u = x - 3
\]

Where \( T_{r}(t) \) and \( T_{r}(u) \) are Chebyshev polynomials of the first kind.

\[
\text{where } P(x) = \sum_{r=0}^{2} c_r T(r, x), \\
\text{and } Q(x) = \sum_{r=0}^{2} d_r T(r, x), \text{ with } t=2(-)^r -1.
\]

For \( x \) near zero, \( Y(x) \approx \frac{1}{\pi x} \). This approximation is used when \( x \) is sufficiently small for the result to be correct to machine precision. For extremely small \( x \), there is a danger of overflow in calculating \( \frac{1}{\pi x} \) and for such arguments the routine will fail.

For very large \( x \), it becomes impossible to provide results with any reasonable accuracy (see Section 7), hence the routine fails. Such arguments contain insufficient information to determine the phase of oscillation of \( Y(x) \), only the amplitude, \( \frac{1}{\sqrt{\pi x}} \), can be determined and this is returned on soft failure. The range for which this occurs is roughly related to machine precision; the routine will fail if \( x > 1/\text{machine precision} \) (see the Users’ Note for your implementation for details).

4. References

5. Parameters

1: \( X \) -- DOUBLE PRECISION  
Input
On entry: the argument \( x \) of the function. Constraint: \( X > 0. \)

2: IFAIL -- INTEGER  
Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential
CHAPTER 22. NAG LIBRARY ROUTINES

Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL = 1
X is too large. On soft failure the routine returns the

\[ \frac{\sqrt{2}}{\pi x} \]

amplitude of the Y oscillation, \(-\frac{\sqrt{2}}{\pi x}\).

IFAIL = 2
X \leq 0.0, Y is undefined. On soft failure the routine
1
returns zero.

IFAIL = 3
X is too close to zero, there is a danger of overflow. On
soft failure, the routine returns the value of Y(x) at the
1
smallest valid argument.

7. Accuracy

Let (\delta) be the relative error in the argument and E be the
absolute error in the result. (Since Y(x) oscillates about zero,
1
absolute error and not relative error is significant, except for
very small x.)

If (\delta) is somewhat larger than the machine precision (e.g. if
(delta) is due to data errors etc), then E and (\delta) are
approximately related by:

\[ E = |xY(x) - Y(x)| \delta \]

(provided E is also within machine bounds). Figure 1 displays the
behaviour of the amplification factor |xY(x) - Y(x)|.

Figure 1
Please see figure in printed Reference Manual
However, if \((\delta)\) is of the same order as machine precision, then rounding errors could make \(E\) slightly larger than the above relation predicts.

For very small \(x\), absolute error becomes large, but the relative error in the result is of the same order as \((\delta)\).

For very large \(x\), the above relation ceases to apply. In this region, \(Y(x) \approx \frac{2(\pi)}{x} \sin(x - \frac{3(\pi)}{4})\). The amplitude \(\frac{2(\pi)}{x}\) can be calculated with reasonable accuracy for all \(x\), but \(\sin(x - \frac{3(\pi)}{4})\) cannot. If \(x - \frac{3(\pi)}{4}\) is written as \(2N(\pi) + (\theta)\) where \(N\) is an integer and \(0 \leq (\theta) < 2(\pi)\), then \(\sin(x - \frac{3(\pi)}{4})\) is determined by \((\theta)\) only. If \(x > (\delta)\), \((\theta)\) cannot be determined with any accuracy at all. Thus if \(x\) is greater than, or of the order of, the inverse of the machine precision, it is impossible to calculate the phase of \(Y(x)\) and the routine must fail.

8. Further Comments

For details of the time taken by the routine see the Users’ Note for your implementation.

9. Example

The example program reads values of the argument \(x\) from a file, evaluates the function at each value of \(x\) and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
Returns the value of the Bessel Function $J_0(x)$

— nags.ht —

\begin{verbatim}
S17AEF(3NAG) Foundation Library (12/10/92) S17AEF(3NAG)
S17 -- Approximations of Special Functions
S17AEF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S17AEF returns the value of the Bessel Function $J_0(x)$, via the routine name.

2. Specification

\begin{verbatim}
DOUBLE PRECISION FUNCTION S17AEF (X, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X
\end{verbatim}

3. Description

This routine evaluates an approximation to the Bessel Function of the first kind $J_0(x)$.

Note: $J_0(-x)=J_0(x)$, so the approximation need only consider $x\geq0$.

The routine is based on three Chebyshev expansions:

For $0<x\leq8$,

$$J_0(x) = \sum_{r=0}^{2} a_r T_r(t),$$

where $t=2(-x)^{1/4}$.
For $x > 8$,

$$J(x) = \frac{1}{\pi x} \left\{ P(x) \cos(x) - Q(x) \sin(x) \right\}$$

where

$$P(x) = \sum_{r=0}^{\infty} b^r T(r),$$

and

$$Q(x) = \sum_{r=0}^{\infty} c^r T(r),$$

with $t = 2^{1/2} - 1$.

For $x$ near zero, $J(x) \approx 1$. This approximation is used when $x$ is sufficiently small for the result to be correct to machine precision.

For very large $x$, it becomes impossible to provide results with any reasonable accuracy (see Section 7), hence the routine fails. Such arguments contain insufficient information to determine the phase of oscillation of $J(x)$; only the amplitude, $\sqrt{\frac{1}{\pi |x|}}$, can be determined and this is returned on soft failure. The range for which this occurs is roughly related to the machine precision; the routine will fail if $|x| \approx 1/$machine precision (see the Users’ Note for your implementation).

4. References

5. Parameters

1: X -- DOUBLE PRECISION

On entry: the argument $x$ of the function.
2: IFAIL -- INTEGER

On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

X is too large. On soft failure the routine returns the amplitude of the J oscillation, \( \frac{2}{\pi |x|} \).

7. Accuracy

Let (delta) be the relative error in the argument and E be the absolute error in the result. (Since J (x) oscillates about zero, absolute error and not relative error is significant.)

If (delta) is somewhat larger than the machine precision (e.g. if (delta) is due to data errors etc), then E and (delta) are approximately related by:

\[ E \approx |xJ (x)| (\delta) \]

( provided E is also within machine bounds). Figure 1 displays the behaviour of the amplification factor \( |xJ (x)| \). 

\[ \frac{2}{\pi |x|} \]

However, if (delta) is of the same order as machine precision, then rounding errors could make E slightly larger than the above relation predicts.

For very large x, the above relation ceases to apply. In this case
22.6. NAGS.HT

region, \( J(x) = \frac{\cos(x)}{\sqrt{\pi|x|}} \). The amplitude
\[
\frac{1}{2} \frac{\cos(x)}{\sqrt{\pi|x|}}
\]
can be calculated with reasonable accuracy for all \( x \)
\[
\frac{1}{\sqrt{\pi|x|}}
\]
but \( \cos(x) \) cannot. If \( x \) is written as
\[
\frac{2N\pi+(\theta)}{4}
\]
where \( N \) is an integer and \( 0 \leq (\theta) < 2\pi \),
\[
\frac{\cos(x)}{2N\pi+(\theta)}
\]
then \( \cos(x) \) is determined by \( (\theta) \) only. If \( x > -(\delta) \),
\[
\frac{\cos(x)}{4}
\]
(\( \theta \)) cannot be determined with any accuracy at all. Thus if \( x \)
is greater than, or of the order of, the inverse of the machine
precision, it is impossible to calculate the phase of \( J(x) \) and
the routine must fail.

8. Further Comments

For details of the time taken by the routine see the Users’ Note
for your implementation.

9. Example

Returns the value of the Bessel Function \( J_1(x) \)
Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S17AFF returns the value of the Bessel Function $J_1(x)$, via the routine name.

2. Specification

```fortran
DOUBLE PRECISION FUNCTION S17AFF (X, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X
```

3. Description

This routine evaluates an approximation to the Bessel Function of the first kind $J_1(x)$.

Note: $J_1(-x) = -J_1(x)$, so the approximation need only consider $x > 0$.

The routine is based on three Chebyshev expansions:

For $0 < x < 8$,

$$
J_1(x) = -\sum_{r=0}^{2} a_r T_r(t), \quad \text{with } t = 2(t_x - 1),
$$

where $t_x = t - \pi$.

For $x > 8$,

$$
J_1(x) = \frac{1}{\pi} \left\{ \begin{array}{c}
\frac{3}{4} (3\pi)^{1/2} (3\pi) \\
\frac{1}{4} (4) \end{array} \right\}
$$

where $P(x)$ and $Q(x)$ are the Chebyshev polynomials.

where \( P(x) = \sum_{r=0}^{2} b_r T(r), \)
and \( Q(x) = \sum_{r=0}^{2} c_r T(r), \)
with \( t = 2(\frac{x}{\pi}) - 1. \)

For \( x \) near zero, \( J(x) \approx -\). This approximation is used when \( x \) is sufficiently small for the result to be correct to machine precision.

For very large \( x \), it becomes impossible to provide results with any reasonable accuracy (see Section 7), hence the routine fails. Such arguments contain insufficient information to determine the phase of oscillation of \( J(x) \); only the amplitude, \( \sqrt{2/\pi|x|} \), can be determined and this is returned on soft failure. The range for which this occurs is roughly related to the machine precision; the routine will fail if \( |x| > 1/\text{machine precision} \) (see the Users’ Note for your implementation for details).

---

Returns a value for the Airy function, \( Ai(x) \)

— nags.ht —

\begin{verbatim}

\end{verbatim}
\end{scroll}
\end{page}
1. Purpose

S17AGF returns a value for the Airy function, \( \text{Ai}(x) \), via the routine name.

2. Specification

\[
\text{DOUBLE PRECISION FUNCTION S17AGF (X, IFAIL)}
\]

\[
\text{INTEGER IFAIL}
\]

\[
\text{DOUBLE PRECISION X}
\]

3. Description

This routine evaluates an approximation to the Airy function, \( \text{Ai}(x) \). It is based on a number of Chebyshev expansions:

For \( x < -5 \),

\[
\text{Ai}(x) = \frac{a(t) \sin z - b(t) \cos z}{1/4} \sqrt{\pi 2/3} (-x)
\]

where \( z = \frac{\sqrt{\pi}}{4} \sqrt{-x} \), and \( a(t) \) and \( b(t) \) are expansions in the variable \( t = -2(\frac{\pi}{3}) - 1 \).

For \(-5 \leq x \leq 0\),

\[
\text{Ai}(x) = f(t) - x g(t),
\]

where \( f \) and \( g \) are expansions in \( t = -2(\frac{\pi}{3}) - 1 \).

For \( 0 < x < 4.5 \),

\[\text{Ai}(x) = e^{-\frac{3x}{2}} y(t),\]

where \(y\) is an expansion in \(t = \frac{4x}{9} - 1\).

For \(4.5 \leq x < 9\),

\[\text{Ai}(x) = e^{-\frac{5x}{2}} u(t),\]

where \(u\) is an expansion in \(t = \frac{4x}{9} - 3\).

For \(x \geq 9\),

\[\text{Ai}(x) = e^{-\frac{z}{1/4}} \frac{v(t)}{x^{2/3}},\]

where \(z = -\sqrt[3]{x}\) and \(v\) is an expansion in \(t = 2(\frac{z}{3}) - 1\).

For \(|x| < \text{the machine precision}\), the result is set directly to \(\text{Ai}(0)\). This both saves time and guards against underflow in intermediate calculations.

For large negative arguments, it becomes impossible to calculate the phase of the oscillatory function with any precision and so the routine must fail. This occurs if \(x < (\frac{3}{2(\epsilon)})\), where \((\epsilon)\) is the machine precision.

For large positive arguments, where \(\text{Ai}\) decays in an essentially exponential manner, there is a danger of underflow so the routine must fail.

4. References

5. Parameters

1: X -- DOUBLE PRECISION Input
On entry: the argument x of the function.

2: IFAIL -- INTEGER
   Input/Output
   On entry: IFAIL must be set to 0, -1 or 1. For users not
   familiar with this parameter (described in the Essential
   Introduction) the recommended value is 0.
   On exit: IFAIL = 0 unless the routine detects an error (see
   Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
   X is too large and positive. On soft failure, the routine
   returns zero.

IFAIL= 2
   X is too large and negative. On soft failure, the routine
   returns zero.

7. Accuracy

For negative arguments the function is oscillatory and hence
absolute error is the appropriate measure. In the positive region
the function is essentially exponential-like and here relative
error is appropriate. The absolute error, E, and the relative
error, (epsilon), are related in principle to the relative error
in the argument, (delta), by

\[ E = |x\text{Ai}'(x)| (\delta), \quad (\epsilon) = \frac{|x\text{Ai}'(x)|}{|\text{Ai}(x)|} (\delta). \]

In practice, approximate equality is the best that can be
expected. When (delta), (epsilon) or E is of the order of the
machine precision, the errors in the result will be somewhat
larger.

For small x, errors are strongly damped by the function and hence
will be bounded by the machine precision.

For moderate negative x, the error behaviour is oscillatory but
the amplitude of the error grows like

\[ \text{amplitude} \propto \left( \frac{\text{E}}{|x|} \right)^{5/4} \]

\[ \propto \left( \frac{\delta}{\epsilon} \right)^{5/4} \frac{1}{\sqrt{\pi}}. \]
However the phase error will be growing roughly like \(-\sqrt[3]{|x|}\) and hence all accuracy will be lost for large negative arguments due to the impossibility of calculating \(\sin\) and \(\cos\) to any

\[
\frac{2}{3} \quad \frac{3}{2} \quad 1
\]

accuracy if \(-\sqrt[3]{|x|} > -----\).

\[
\frac{2}{3} \quad \frac{3}{2} \quad (\delta)
\]

For large positive arguments, the relative error amplification is considerable:

\[
\frac{\epsilon}{3} \quad \frac{3}{2} \quad \frac{3}{2} \quad \sqrt[3]{x}.
\]

\[
\frac{\epsilon}{3} \quad \frac{3}{2} \quad (\delta)
\]

This means a loss of roughly two decimal places accuracy for arguments in the region of 20. However very large arguments are not possible due to the danger of setting underflow and so the errors are limited in practice.

8. Further Comments

None.

9. Example

The example program reads values of the argument \(x\) from a file, evaluates the function at each value of \(x\) and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
Returns a value of the Airy function, $Bi(x)$

not included in the Foundation Library.

1. Purpose

S17AHF returns a value of the Airy function, $Bi(x)$, via the
routine name.

2. Specification

\begin{verbatim}
DOUBLE PRECISION FUNCTION S17AHF (X, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X
\end{verbatim}

3. Description

This routine evaluates an approximation to the Airy function
$Bi(x)$. It is based on a number of Chebyshev expansions.

For $x<5$,

\[
Bi(x) = \frac{a(t) \cos z + b(t) \sin z}{1/4 \pi^{2/3}(-x)}
\]

where $z = \frac{-\pi}{3} - \sqrt{-x}$ and $a(t)$ and $b(t)$ are expansions in the
For $-5 \leq x \leq 0$,

$$Bi(x) = \sqrt{3(f(t) + xg(t))},$$

where $f$ and $g$ are expansions in $t = -2(-) -1$.  \( 5 \)

For $0 < x < 4.5$,

$$Bi(x) = e^{\frac{11x}{8}} y(t),$$

where $y$ is an expansion in $t = 4x/9 - 1$.  \( 5 \)

For $4.5 \leq x \leq 9$,

$$Bi(x) = e^{\frac{5x}{2}} v(t),$$

where $v$ is an expansion in $t = 4x/9 - 3$.  \( 5 \)

For $x \geq 9$,

$$Bi(x) = \frac{e^{u(t)}}{x^{2/3}},$$

where $z = -\sqrt{x}$ and $u$ is an expansion in $t = 2(-) - 1$.  \( 18 \)

For $|x| < \text{the machine precision}$, the result is set directly to $Bi(0)$. This both saves time and avoids possible intermediate underflows.

For large negative arguments, it becomes impossible to calculate the phase of the oscillating function with any accuracy so the
routine must fail. This occurs if \( x \leq -\frac{1}{\sqrt{2\epsilon}} \), where \( \epsilon \) is the machine precision.

For large positive arguments, there is a danger of causing overflow since \( B_i \) grows in an essentially exponential manner, so the routine must fail.

4. References

5. Parameters

1: \( X \) -- DOUBLE PRECISION Input
   On entry: the argument \( x \) of the function.

2: IFAIL -- INTEGER Input/Output
   On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
   On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
   \( x \) is too large and positive. On soft failure, the routine returns zero.

IFAIL= 2
   \( x \) is too large and negative. On soft failure, the routine returns zero.

7. Accuracy

For negative arguments the function is oscillatory and hence absolute error is the appropriate measure. In the positive region the function is essentially exponential-like and here relative error is appropriate. The absolute error, \( E \), and the relative error, \( \epsilon \), are related in principle to the relative error in the argument, \( \delta \), by

\[ | xB_i'(x) | \]
\[ E^* = |xBi'(x)|(\delta), \quad (\epsilon)^* = \frac{| \epsilon |}{|Bi(x)|}. \]

In practice, approximate equality is the best that can be expected. When \((\delta), (\epsilon)\) or \(E\) is of the order of the machine precision, the errors in the result will be somewhat larger.

For small \(x\), errors are strongly damped and hence will be bounded essentially by the machine precision.

For moderate to large negative \(x\), the error behaviour is clearly oscillatory but the amplitude of the error grows like amplitude 5/4
\[
\begin{align*}
(\frac{E}{\delta}) |x| \\
(\frac{\epsilon}{\delta})^* \quad \frac{|x|}{\pi} \\
\end{align*}
\]

However the phase error will be growing roughly as \([-\sqrt{|x|}\] and \[3\]

hence all accuracy will be lost for large negative arguments.

This is due to the impossibility of calculating \(\sin\) and \(\cos\) to
\[
\begin{align*}
2 / 3 \\
\sqrt{\delta} \\
\end{align*}
\]

any accuracy if \(-\sqrt{|x|} > \frac{1}{3}\) (\(\delta\)).

For large positive arguments, the relative error amplification is considerable:

\[
\begin{align*}
(\epsilon) / 3 \\
\frac{\epsilon}{\delta \sqrt{x}} \\
\end{align*}
\]

This means a loss of roughly two decimal places accuracy for arguments in the region of 20. However very large arguments are not possible due to the danger of causing overflow and errors are therefore limited in practice.

8. Further Comments

For details of the time taken by the routine see the Users’ Note
9. Example

The example program reads values of the argument $x$ from a file, evaluates the function at each value of $x$ and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

---

Value of the derivative of the Airy function $Ai(x)$

--- nags.ht ---

S17AJF returns a value of the derivative of the Airy function $Ai(x)$, via the routine name.

2. Specification

\begin{verbatim}
DOUBLE PRECISION FUNCTION S17AJF (X, IFAIL)
INTEGER IFAIL
\end{verbatim}
DOUBLE PRECISION X

3. Description

This routine evaluates an approximation to the derivative of the Airy function Ai(x). It is based on a number of Chebyshev expansions.

For \( x \leq -5 \),

\[
Ai'(x) = -x \left[ a(t) \cos z + \frac{b(t)}{z^2} \sin z \right],
\]

where \( z = \frac{\pi}{3} + (\zeta) \), \( \zeta = -\sqrt{-x} \) and \( a(t) \) and \( b(t) \) are expansions in variable \( t = -2(\frac{1}{x}) - 1 \).

For \(-5 \leq x < 0\),

\[
Ai'(x) = x \left( f(t) - g(t) \right),
\]

where \( f(t) \) and \( g(t) \) are expansions in \( t = -2(\frac{1}{x}) - 1 \).

For \( 0 < x < 4.5 \),

\[
Ai'(x) = e^{-\frac{11x}{8}} y(t),
\]

where \( y(t) \) is an expansion in \( t = 4(\frac{1}{x}) - 1 \).

For \( 4.5 \leq x < 9 \),

\[
Ai'(x) = e^{-\frac{5x}{2}} v(t),
\]

where \( v(t) \) is an expansion in \( t = 4(\frac{1}{x}) - 3 \).
For \( x \geq 9 \),

\[
\begin{align*}
4 \quad &-z \\
\text{Ai}'(x) &= \sqrt{-x} e^{u(t)},
\end{align*}
\]

where \( z = -\sqrt{x} \) and \( u(t) \) is an expansion in \( t = 2(\sqrt{-1})^{-1} \).

For \(|x| < \) the square of the machine precision, the result is set directly to \( \text{Ai}'(0) \). This both saves time and avoids possible intermediate underflows.

For large negative arguments, it becomes impossible to calculate a result for the oscillating function with any accuracy and so the routine must fail. This occurs for \( x < -(\frac{4}{7})(\sqrt{\pi}) \), where \( \epsilon \) is the machine precision.

For large positive arguments, where \( \text{Ai}' \) decays in an essentially exponential manner, there is a danger of underflow so the routine must fail.

4. References

5. Parameters

1: \( X -- \text{DOUBLE PRECISION} \) Input
   On entry: the argument \( x \) of the function.

2: \( IFAIL -- \text{INTEGER} \) Input/Output
   On entry: \( IFAIL \) must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

   On exit: \( IFAIL = 0 \) unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:
IFAIL= 1
   X is too large and positive. On soft failure, the routine returns zero.

IFAIL= 2
   X is too large and negative. On soft failure, the routine returns zero.

7. Accuracy

For negative arguments the function is oscillatory and hence absolute error is the appropriate measure. In the positive region the function is essentially exponential in character and here relative error is needed. The absolute error, E, and the relative error, (epsilon), are related in principle to the relative error in the argument, (delta), by

\[
E \approx \left| \frac{2}{x \, Ai(x)} \right| \left| \frac{x \, Ai(x)}{\epsilon} \right| \left| \frac{\epsilon}{Ai'(x)} \right|
\]

In practice, approximate equality is the best that can be expected. When (delta), (epsilon) or E is of the order of the machine precision, the errors in the result will be somewhat larger.

For small x, positive or negative, errors are strongly attenuated by the function and hence will be roughly bounded by the machine precision.

For moderate to large negative x, the error, like the function, is oscillatory; however the amplitude of the error grows like

\[
\frac{7/4}{\sqrt{\pi}} \left| x \right|
\]

Therefore it becomes impossible to calculate the function with any accuracy if \( |x| > \frac{7/4}{\sqrt{\delta\pi}} \).

For large positive x, the relative error amplification is considerable:
\[
\frac{\epsilon}{3} = \sqrt[3]{x}.
\]

However, very large arguments are not possible due to the danger of underflow. Thus in practice error amplification is limited.

8. Further Comments

None.

9. Example

The example program reads values of the argument \( x \) from a file, evaluates the function at each value of \( x \) and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

S17 -- Approximations of Special Functions S17AKF
S17AKF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details.
The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S17AKF returns a value for the derivative of the Airy function Bi(x), via the routine name.

2. Specification

```plaintext
DOUBLE PRECISION FUNCTION S17AKF (X, IFAIL)
    INTEGER IFAIL
    DOUBLE PRECISION X
```

3. Description

This routine calculates an approximate value for the derivative of the Airy function Bi(x). It is based on a number of Chebyshev expansions.

For \( x \leq -5 \),

\[
\frac{4}{(\pi)^2} \left\{ \begin{array}{l}
\frac{b(t)}{z}\left(-a(t)\sin z + \frac{\cos z}{(zeta)}\right), \\
-\frac{x}{z}\left[-a(t)\sin z + \frac{\cos z}{(zeta)}\right].
\end{array} \right.
\]

where \( z = \frac{\pi}{4} + (zeta), \) \((zeta) = -\sqrt{-x} \) and \( a(t) \) and \( b(t) \) are expansions in the variable \( t = -2^{(x)} - 1 \).

For \(-5 < x \leq 0\),

\[
\frac{2}{3} \sqrt{3} \left[ (f(t) + g(t)) \right],
\]

where \( f \) and \( g \) are expansions in \( t = -2^{(x)} - 1 \).

For \( 0 < x < 4.5 \),

\[
\frac{3x}{2} e^{y(t)},
\]
where \( y(t) \) is an expansion in \( t = \frac{4x}{9} - 1 \).

For \( 4.5 \leq x < 9 \),

\[
\frac{21x}{8} \quad Bi'(x) = e^{u(t)},
\]

where \( u(t) \) is an expansion in \( t = \frac{4x}{9} - 3 \).

For \( x \geq 9 \),

\[
\frac{4}{3} z \quad Bi'(x) = \sqrt{x} e^{v(t)},
\]

\[
\frac{2}{3} \quad (18)
\]

where \( z = -\sqrt{x} \) and \( v(t) \) is an expansion in \( t = \frac{2}{3} (z - 1) \).

For \( |x| < \) the square of the machine precision, the result is set directly to \( Bi'(0) \). This saves time and avoids possible underflows in calculation.

For large negative arguments, it becomes impossible to calculate a result for the oscillating function with any accuracy so the routine must fail. This occurs for \( x < \left( -\frac{4}{7} \right) \), where \( \varepsilon \) is the machine precision.

For large positive arguments, where \( Bi' \) grows in an essentially exponential manner, there is a danger of overflow so the routine must fail.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

---

Values for the Bessel functions \( Y_{\nu+n}(z) \)
Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S17DCF returns a sequence of values for the Bessel functions $Y_{(nu)}(z)$ for complex $z$, non-negative $(nu)$ and $n=0,1,...,N-1$, $(nu)+n$ with an option for exponential scaling.

2. Specification

SUBROUTINE S17DCF (FNU, Z, N, SCALE, CY, NZ, CWRK, IFAIL)
INTEGER N, NZ, IFAIL
DOUBLE PRECISION FNU
COMPLEX(KIND(1.0D0)) Z, CY(N), CWRK(N)
CHARACTER*1 SCALE

3. Description

This subroutine evaluates a sequence of values for the Bessel function $Y_{(nu)}(z)$, where $z$ is complex, $-(\pi) < \arg z \leq (\pi)$, and $(nu)$ is the real, non-negative order. The $N$-member sequence is generated for orders $(nu)$, $(nu)+1,...,(nu)+N-1$. Optionally, the sequence is scaled by the factor $e^{-|Im z|}$.

Note: although the routine may not be called with $(nu)$ less than zero, for negative orders the formula

$$Y_{(nu)}(z) = Y_{(nu)}(z) \cos((\pi)(nu)) + J_{(nu)}(z) \sin((\pi)(nu))$$

may be used.

The routine is derived from the routine CBESY in Amos [2]. It is based on the relation

$$Y_{(nu)}(z) = \frac{H_{(nu)}(z)}{2i},$$

and $H_{(nu)}(z)$ are the Hankel functions of the first and second kinds respectively (see S17DLF).

When $N$ is greater than 1, extra values of $Y_{(nu)}(z)$ are computed
using recurrence relations.

For very large \(|z|\) or \((\nu) + N - 1\), argument reduction will cause total loss of accuracy, and so no computation is performed. For slightly smaller \(|z|\) or \((\nu) + N - 1\), the computation is performed but results are accurate to less than half of machine precision. If \(|z|\) is very small, near the machine underflow threshold, or \((\nu) + N - 1\) is too large, there is a risk of overflow and so no computation is performed. In all the above cases, a warning is given by the routine.

4. References

5. Parameters

1: \textbf{FNU -- DOUBLE PRECISION} \hspace{1cm} \textbf{Input}
   On entry: the order, \((\nu)\), of the first member of the sequence of functions. Constraint: FNU \(\geq 0.0\).

2: \textbf{Z -- COMPLEX(KIND(1.0D0))} \hspace{1cm} \textbf{Input}
   On entry: the argument, \(z\), of the functions. Constraint: Z \(/= (0.0, 0.0)\).

3: \textbf{N -- INTEGER} \hspace{1cm} \textbf{Input}
   On entry: the number, \(N\), of members required in the sequence \(Y(\nu)(z), Y(\nu+1)(z), \ldots, Y(\nu+N-1)(z)\). Constraint: N \(\geq 1\).

4: \textbf{SCALE -- CHARACTER*1} \hspace{1cm} \textbf{Input}
   On entry: the scaling option.

   If SCALE = 'U', the results are returned unscaled.

   If SCALE = 'S', the results are returned scaled by the factor \(|\text{Im}z|\).

   Constraint: SCALE = 'U' or 'S'.

5: \textbf{CY(N) -- COMPLEX(KIND(1.0D0)) array} \hspace{1cm} \textbf{Output}
   On exit: the \(N\) required function values: CY(i) contains \(Y(\nu+i-1)(z)\), for \(i=1,2,\ldots,N\).
6: NZ -- INTEGER
On exit: the number of components of CY that are set to zero
due to underflow. The positions of such components in the
array CY are arbitrary.

7: CWK(N) -- COMPLEX(KIND(1.0D)) array
Workspace

8: IFAIL -- INTEGER
On entry: IFAIL must be set to 0, -1 or 1. For users not
familiar with this parameter (described in the Essential
Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see
Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
On entry FNU < 0.0,
or Z = (0.0, 0.0),
or N < 1,
or SCALE /= 'U' or 'S'.

IFAIL= 2
No computation has been performed due to the likelihood of
overflow, because ABS(Z) is less than a machine-dependent
threshold value (given in the Users' Note for your
implementation).

IFAIL= 3
No computation has been performed due to the likelihood of
overflow, because FNU + N - 1 is too large - how large
depends on Z as well as the overflow threshold of the
machine.

IFAIL= 4
The computation has been performed, but the errors due to
argument reduction in elementary functions make it likely
that the results returned by S17DCF are accurate to less
than half of machine precision. This error exit may occur if
either ABS(Z) or FNU + N - 1 is greater than a machine-
dependent threshold value (given in the Users' Note for
IFAIL = 5
No computation has been performed because the errors due to argument reduction in elementary functions mean that all precision in results returned by S17DCF would be lost. This error exit may occur if either ABS(Z) or FNU + N - 1 is greater than a machine-dependent threshold value (given in the Users’ Note for your implementation).

IFAIL = 6
No results are returned because the algorithm termination condition has not been met. This may occur because the parameters supplied to S17DCF would have caused overflow or underflow.

7. Accuracy

All constants in subroutine S17DCF are given to approximately 18 digits of precision. Calling the number of digits of precision in the floating-point arithmetic being used t, then clearly the maximum number of correct digits in the results obtained is limited by \( p = \min(t, 18) \). Because of errors in argument reduction when computing elementary functions inside S17DCF, the actual number of correct digits is limited, in general, by \( p - s \), where

\[
10^{- \max(1, |\log |Z||, |\log (\nu)|)}
\]

represents the number of digits lost due to the argument reduction. Thus the larger the values of \(|Z|\) and \((\nu)\), the less the precision in the result. If S17DCF is called with \( N > 1 \), then computation of function values via recurrence may lead to some further small loss of accuracy.

If function values which should nominally be identical are computed by calls to S17DCF with different base values of \((\nu)\) and different \(N\), the computed values may not agree exactly. Empirical tests with modest values of \((\nu)\) and \(Z\) have shown that the discrepancy is limited to the least significant 3-4 digits of precision.

8. Further Comments

The time taken by the routine for a call of S17DCF is approximately proportional to the value of \(N\), plus a constant. In general it is much cheaper to call S17DCF with \(N\) greater than 1, rather than to make \(N\) separate calls to S17DCF.

Paradoxically, for some values of \(Z\) and \((\nu)\), it is cheaper to call S17DCF with a larger value of \(N\) than is required, and then discard the extra function values returned. However, it is not possible to state the precise circumstances in which this is
likely to occur. It is due to the fact that the base value used
to start recurrence may be calculated in different regions for
different \( N \), and the costs in each region may differ greatly.

Note that if the function required is \( y(x) \) or \( y(x) \), i.e., \( (\nu)_{0,1} \)
\[ = 0.0 \text{ or } 1.0, \] where \( x \) is real and positive, and only a single
unscaled function value is required, then it may be much cheaper
to call \texttt{S17ACF} or \texttt{S17ADF} respectively.

9. Example

The example program prints a caption and then proceeds to read
sets of data from the input data stream. The first datum is a
value for the order \( \nu \), the second is a complex value for the
argument, \( z \), and the third is a value for the parameter \( \text{SCALE} \).
The program calls the routine with \( N = 2 \) to evaluate the function
for orders \( \nu \) and \( \nu + 1 \), and it prints the results. The
process is repeated until the end of the input data stream is
encountered.

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.
Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S17DEF returns a sequence of values for the Bessel functions $J_\nu(z)$ for complex $z$, non-negative $\nu$ and $n=0,1,\ldots,N-1$, with an option for exponential scaling.

2. Specification

```fortran
SUBROUTINE S17DEF (FNU, Z, N, SCALE, CY, NZ, IFAIL)
INTEGER N, NZ, IFAIL
DOUBLE PRECISION FNU
COMPLEX(KIND(1.0D0)) Z, CY(N)
CHARACTER*1 SCALE
```

3. Description

This subroutine evaluates a sequence of values for the Bessel function $J_\nu(z)$, where $z$ is complex, $-(\pi) < \arg z \leq (\pi)$, and $\nu$ is the real, non-negative order. The $N$-member sequence is generated for orders $\nu$, $\nu+1$, $\ldots$, $\nu+N-1$. Optionally, the sequence is scaled by the factor $e^{-|\text{Im } z|}$.

Note: although the routine may not be called with $\nu$ less than zero, for negative orders the formula

$$
J_\nu(z) = J_{-\nu}(z) \cos((\pi)(\nu)) - Y_\nu(z) \sin((\pi)(\nu))
$$

may be used (for the Bessel function $Y_\nu(z)$, see S17DCF).

The routine is derived from the routine CBESJ in Amos [2]. It is based on the relations

$$
J_\nu(z) = e^{-(\nu)(pi)i/2} (iz) \quad \text{for } \nu \geq 0.0
$$

and

$$
J_\nu(z) = e^{-(\nu)(pi)i/2} (-iz) \quad \text{for } \nu < 0.0
$$

The Bessel function $I_\nu(z)$ is computed using a variety of techniques depending on the region under consideration.

When $N$ is greater than 1, extra values of $J_\nu(z)$ are computed
using recurrence relations.

For very large $|z|$ or $((\nu)+N-1)$, argument reduction will cause total loss of accuracy, and so no computation is performed. For slightly smaller $|z|$ or $((\nu)+N-1)$, the computation is performed but results are accurate to less than half of machine precision. If $\text{Im } z$ is large, there is a risk of overflow and so no computation is performed. In all the above cases, a warning is given by the routine.

4. References

5. Parameters

1: FNU -- DOUBLE PRECISION Input
   On entry: the order, $(\nu)$, of the first member of the sequence of functions. Constraint: FNU $\geq 0.0$.

2: Z -- COMPLEX(KIND(1.0D0)) Input
   On entry: the argument $z$ of the functions.

3: N -- INTEGER Input
   On entry: the number, $N$, of members required in the sequence $J_{(\nu)}(z), J_{(\nu)+1}(z), \ldots, J_{(\nu)+N-1}(z)$. Constraint: $N \geq 1$.

4: SCALE -- CHARACTER*1 Input
   On entry: the scaling option.
   
   - If SCALE = 'U', the results are returned unscaled.
   - If SCALE = 'S', the results are returned scaled by the factor $e^{-|\text{Im } z|}$.
   
   Constraint: SCALE = 'U' or 'S'.

5: CY(N) -- COMPLEX(KIND(1.0D0)) array Output
   On exit: the $N$ required function values: CY(i) contains $J_{(\nu)+i-1}(z)$, for $i=1,2,\ldots,N$.

6: NZ -- INTEGER Output
   On exit: the number of components of CY that are set to zero.
due to underflow. If NZ > 0, then elements CY(N-NZ+1), CY(N-NZ+2),...,CY(N) are set to zero.

7: IFAIL -- INTEGER Input/Output
   On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
   On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1
   On entry FNU < 0.0,
   or N < 1,
   or SCALE /= 'U' or 'S'.

IFAIL= 2
   No computation has been performed due to the likelihood of overflow, because Im Z is larger than a machine-dependent threshold value (given in the Users’ Note for your implementation). This error exit can only occur when SCALE = 'U'.

IFAIL= 3
   The computation has been performed, but the errors due to argument reduction in elementary functions make it likely that the results returned by S17DEF are accurate to less than half of machine precision. This error exit may occur if either ABS(Z) or FNU + N - 1 is greater than a machine-dependent threshold value (given in the Users’ Note for your implementation).

IFAIL= 4
   No computation has been performed because the errors due to argument reduction in elementary functions mean that all precision in results returned by S17DEF would be lost. This error exit may occur when either ABS(Z) or FNU + N - 1 is greater than a machine-dependent threshold value (given in the Users’ Note for your implementation).

IFAIL= 5
No results are returned because the algorithm termination condition has not been met. This may occur because the parameters supplied to S17DEF would have caused overflow or underflow.

7. Accuracy

All constants in subroutine S17DEF are given to approximately 18 digits of precision. Calling the number of digits of precision in the floating-point arithmetic being used t, then clearly the maximum number of correct digits in the results obtained is limited by p=min(t,18). Because of errors in argument reduction when computing elementary functions inside S17DEF, the actual number of correct digits is limited, in general, by p–s, where s=\max(1,\log_{10}|z|,\log_{10}|\nu|) represents the number of digits lost due to the argument reduction. Thus the larger the values of |z| and (\nu), the less the precision in the result. If S17DEF is called with N>1, then computation of function values via recurrence may lead to some further small loss of accuracy.

If function values which should nominally be identical are computed by calls to S17DEF with different base values of (\nu) and different N, the computed values may not agree exactly. Empirical tests with modest values of (\nu) and z have shown that the discrepancy is limited to the least significant 3–4 digits of precision.

8. Further Comments

The time taken by the routine for a call of S17DEF is approximately proportional to the value of N, plus a constant. In general it is much cheaper to call S17DEF with N greater than 1, rather than to make N separate calls to S17DEF.

Paradoxically, for some values of z and (\nu), it is cheaper to call S17DEF with a larger value of N than is required, and then discard the extra function values returned. However, it is not possible to state the precise circumstances in which this is likely to occur. It is due to the fact that the base value used to start recurrence may be calculated in different regions for different N, and the costs in each region may differ greatly.

Note that if the function required is J_0(x) or J_1(x), i.e., (\nu) = 0.0 or 1.0, where x is real and positive, and only a single unscaled function value is required, then it may be much cheaper to call S17AEF or S17AFF respectively.

9. Example
The example program prints a caption and then proceeds to read sets of data from the input data stream. The first datum is a value for the order FNU, the second is a complex value for the argument, Z, and the third is a value for the parameter SCALE.

The program calls the routine with $N = 2$ to evaluate the function for orders FNU and FNU + 1, and it prints the results. The process is repeated until the end of the input data stream is encountered.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

Value of the Airy function $Ai(z)$ or derivative $Ai'(z)$

--- nags.ht ---

S17DGF(3NAG) Foundation Library (12/10/92) S17DGF(3NAG)

S17 -- Approximations of Special Functions

S17DGF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S17DGF returns the value of the Airy function $Ai(z)$ or its derivative $Ai'(z)$ for complex $z$, with an option for exponential
scaling.

2. Specification

SUBROUTINE S17DGF (DERIV, Z, SCALE, AI, NZ, IFAIL)
INTEGER NZ, IFAIL
COMPLEX(KIND(1.0D0)) Z, AI
CHARACTER*1 DERIV, SCALE

3. Description

This subroutine returns a value for the Airy function Ai(z) or its derivative Ai'(z), where z is complex, -(pi) < arg z <= (pi).

\[ \frac{2z}{z^{1/3}} \]

Optionally, the value is scaled by the factor \( e^{2z/3} \).

The routine is derived from the routine CAIRY in Amos [2]. It is based on the relations

\[ \frac{\sqrt[3]{z}}{z} K(w) = \frac{-z}{z^{1/3}} \]

where \( K(\nu) \) is the modified Bessel function and \( w = 2z/z^{1/3} \).

For very large \( |z| \), argument reduction will cause total loss of accuracy, and so no computation is performed. For slightly smaller \( |z| \), the computation is performed but results are accurate to less than half of machine precision. If \( \Re w \) is too large, and the unscaled function is required, there is a risk of overflow and so no computation is performed. In all the above cases, a warning is given by the routine.

4. References

5. Parameters
1: DERIV -- CHARACTER*1
   On entry: specifies whether the function or its derivative
   is required.
   If DERIV = 'F', Ai(z) is returned.
   If DERIV = 'D', Ai'(z) is returned.
   Constraint: DERIV = 'F' or 'D'.

2: Z -- COMPLEX(KIND(1.0D0))
   On entry: the argument z of the function.

3: SCALE -- CHARACTER*1
   On entry: the scaling option.
   If SCALE = 'U', the result is returned unscaled.
   If SCALE = 'S', the result is returned scaled by the factor

   \[
   2z/\sqrt{z/3} e^{-z/3}
   \]
   Constraint: SCALE = 'U' or 'S'.

4: AI -- COMPLEX(KIND(1.0D0))
   On exit: the required function or derivative value.

5: NZ -- INTEGER
   On exit: NZ indicates whether or not AI is set to zero due
   to underflow. This can only occur when SCALE = 'U'.
   If NZ = 0, AI is not set to zero.
   If NZ = 1, AI is set to zero.

6: IFAIL -- INTEGER
   On entry: IFAIL must be set to 0, -1 or 1. For users not
   familiar with this parameter (described in the Essential
   Introduction) the recommended value is 0.
   On exit: IFAIL = 0 unless the routine detects an error (see
   Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
On entry DERIV /= 'F' or 'D'.

or SCALE /= 'U' or 'S'.

IFAIL= 2
No computation has been performed due to the likelihood of overflow, because Re w is too large, where w=2Z\sqrt{Z/3} -- how large depends on Z and the overflow threshold of the machine. This error exit can only occur when SCALE = 'U'.

IFAIL= 3
The computation has been performed, but the errors due to argument reduction in elementary functions make it likely that the result returned by S17DGF is accurate to less than half of machine precision. This error exit may occur if ABS(Z) is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

IFAIL= 4
No computation has been performed because the errors due to argument reduction in elementary functions mean that all precision in the result returned by S17DGF would be lost. This error exit may occur if ABS(Z) is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

IFAIL= 5
No result is returned because the algorithm termination condition has not been met. This may occur because the parameters supplied to S17DGF would have caused overflow or underflow.

7. Accuracy

All constants in subroutine S17DGF are given to approximately 18 digits of precision. Calling the number of digits of precision in the floating-point arithmetic being used t, then clearly the maximum number of correct digits in the results obtained is limited by p=min(t,18). Because of errors in argument reduction when computing elementary functions inside S17DGF, the actual number of correct digits is limited, in general, by p-s, where s=max(1,|\log |z||) represents the number of digits lost due to the argument reduction. Thus the larger the value of |z|, the less the precision in the result.

Empirical tests with modest values of z, checking relations between Airy functions Ai(z), Ai'(z), Bi(z) and Bi'(z), have
shown errors limited to the least significant 3-4 digits of precision.

8. Further Comments

Note that if the function is required to operate on a real argument only, then it may be much cheaper to call S17AGF or S17AJF.

9. Example

The example program prints a caption and then proceeds to read sets of data from the input data stream. The first datum is a value for the parameter DERIV, the second is a complex value for the argument, Z, and the third is a value for the parameter SCALE. The program calls the routine and prints the results. The process is repeated until the end of the input data stream is encountered.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
1. Purpose

S17DHF returns the value of the Airy function \( \text{Bi}(z) \) or its derivative \( \text{Bi}'(z) \) for complex \( z \), with an option for exponential scaling.

2. Specification

```fortran
SUBROUTINE S17DHF (DERIV, Z, SCALE, BI, IFAIL)
INTEGER IFAIL
COMPLEX(KIND(1.0D0)) Z, BI
CHARACTER*1 DERIV, SCALE
```

3. Description

This subroutine returns a value for the Airy function \( \text{Bi}(z) \) or its derivative \( \text{Bi}'(z) \), where \( z \) is complex, \(-\pi < \arg z \leq \pi\).

\[ |\text{Re}(2z^{\nu}/\sqrt[3]{z})| \]

Optionally, the value is scaled by the factor \( e^{\pi z/3} \).

The routine is derived from the routine CBIRY in Amos [2]. It is based on the relations:

\[ \text{Bi}(z) = \frac{1}{\sqrt[3]{z}} \left( I_{-1/3}(w) + I_{1/3}(w) \right), \]

\[ \text{Bi}'(z) = \frac{1}{\sqrt[3]{z}} \left( I_{-2/3}(w) + I_{2/3}(w) \right), \]

where \( I \) is the modified Bessel function and \( w = 2z^{\nu}/\sqrt[3]{z} \).

For very large \(|z|\), argument reduction will cause total loss of accuracy, and no computation is performed. For slightly smaller \(|z|\), the computation is performed but results are accurate to less than half of machine precision. If \( \text{Re} \ z \) is too large, and the unscaled function is required, there is a risk of overflow and so no computation is performed. In all the above cases, a warning is given by the routine.

4. References
5. Parameters

1: DERIV -- CHARACTER*1
   Input
   On entry: specifies whether the function or its derivative
   is required.
   If DERIV = 'F', Bi(z) is returned.
   If DERIV = 'D', Bi'(z) is returned.
   Constraint: DERIV = 'F' or 'D'.

2: Z -- COMPLEX(KIND(1.0D0))
   Input
   On entry: the argument z of the function.

3: SCALE -- CHARACTER*1
   Input
   On entry: the scaling option.
   If SCALE = 'U', the result is returned unscaled.
   If SCALE = 'S', the result is returned scaled by the
   $|\text{Re}(2z\sqrt{z/3})|$
   factor $e^\alpha$.
   Constraint: SCALE = 'U' or 'S'.

4: BI -- COMPLEX(KIND(1.0D0))
   Output
   On exit: the required function or derivative value.

5: IFAIL -- INTEGER
   Input/Output
   On entry: IFAIL must be set to 0, -1 or 1. For users not
   familiar with this parameter (described in the Essential
   Introduction) the recommended value is 0.
   On exit: IFAIL = 0 unless the routine detects an error (see
   Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
On entry DERIV /= 'F' or 'D'.
or SCALE /= 'U' or 'S'.

IFAIL= 2
No computation has been performed due to the likelihood of overflow, because real(Z) is too large - how large depends on the overflow threshold of the machine. This error exit can only occur when SCALE = 'U'.

IFAIL= 3
The computation has been performed, but the errors due to argument reduction in elementary functions make it likely that the result returned by S17DHF is accurate to less than half of machine precision. This error exit may occur if ABS(Z) is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

IFAIL= 4
No computation has been performed because the errors due to argument reduction in elementary functions mean that all precision in the result returned by S17DHF would be lost. This error exit may occur if ABS(Z) is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

IFAIL= 5
No result is returned because the algorithm termination condition has not been met. This may occur because the parameters supplied to S17DHF would have caused overflow or underflow.

7. Accuracy

All constants in subroutine S17DHF are given to approximately 18 digits of precision. Calling the number of digits of precision in the floating-point arithmetic being used t, then clearly the maximum number of correct digits in the results obtained is limited by p=min(t,18). Because of errors in argument reduction when computing elementary functions inside S17DHF, the actual number of correct digits is limited, in general, by p-s, where s=max(1,|log |z||) represents the number of digits lost due to the argument reduction. Thus the larger the value of |z|, the less the precision in the result.

Empirical tests with modest values of z, checking relations between Airy functions Ai(z), Ai'(z), Bi(z) and Bi'(z), have shown errors limited to the least significant 3-4 digits of precision.
8. Further Comments

Note that if the function is required to operate on a real argument only, then it may be much cheaper to call S17AHF or S17AKF.

9. Example

The example program prints a caption and then proceeds to read sets of data from the input data stream. The first datum is a value for the parameter DERIV, the second is a complex value for the argument, Z, and the third is a value for the parameter SCALE. The program calls the routine and prints the results. The process is repeated until the end of the input data stream is encountered.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
1. Purpose

S17DLF returns a sequence of values for the Hankel functions
\( H_n^{(1)}(z) \) or \( H_n^{(2)}(z) \) for complex \( z \), non-negative \( \nu \) and
\( \nu + n \)
\( n = 0, 1, \ldots, N-1 \), with an option for exponential scaling.

2. Specification

```
SUBROUTINE S17DLF (M, FNU, Z, N, SCALE, CY, NZ, IFAIL)
    INTEGER M, N, NZ, IFAIL
    DOUBLE PRECISION FNU
    COMPLEX(KIND(1.0D0)) Z, CY(N)
    CHARACTER*1 SCALE
```

3. Description

This subroutine evaluates a sequence of values for the Hankel
\( H_n^{(1)}(z) \) or \( H_n^{(2)}(z) \), where \( z \) is complex, \(-\pi < \arg z \leq \pi\), and \( \nu \) is the real, non-negative order. The \( N \)-member
sequence is generated for orders \( \nu \), \( \nu + 1 \), \ldots, \( \nu + N-1 \).

Optionally, the sequence is scaled by the factor \( e^{-iz} \) if the
\( (1) \) function is \( H_n^{(1)}(z) \) or by the factor \( e^{iz} \) if the function is
\( (2) \)
\( H_n^{(2)}(z) \).

\( \nu \)

Note: although the routine may not be called with \( \nu \) less than
zero, for negative orders the formulae
\( H_{\nu - \pi i}^{(1)}(z) = e^{\nu \pi i} H_{\nu}^{(1)}(z) \), and \( H_{\nu + \pi i}^{(2)}(z) = e^{\nu \pi i} H_{\nu}^{(2)}(z) \)
\( \nu \)
\( \nu \)
may be used.

The routine is derived from the routine CBESH in Amos [2]. It is
based on the relation
\[ H_{\nu}^{(1)}(z) = \frac{1}{\pi} \sum_{m=0}^{\infty} \frac{(-1)^m}{m! (\nu + m + 1)} \frac{(-z^2)^m}{m! (\nu + m + 1)} \]
\( \nu \)
\( \nu \)
\( \nu \)}
where \( p = i \) ---- if \( m = 1 \) and \( p = -i \) ---- if \( m = 2 \), and the Bessel function \( K^{(2)}_{\nu}(z) \) is computed in the right half-plane only. Continuation of \( K^{(2)}_{\nu}(z) \) to the left half-plane is computed in terms of the Bessel function \( I^{(0)}_{\nu}(z) \). These functions are evaluated using a variety of different techniques, depending on the region under consideration.

When \( N \) is greater than 1, extra values of \( H^{(m)}_{\nu}(z) \) are computed using recurrence relations.

For very large \(|z|\) or \((\nu)+N-1\), argument reduction will cause total loss of accuracy, and so no computation is performed. For slightly smaller \(|z|\) or \((\nu)+N-1\), the computation is performed but results are accurate to less than half of machine precision. If \(|z|\) is very small, near the machine underflow threshold, or \((\nu)+N-1\) is too large, there is a risk of overflow and so no computation is performed. In all the above cases, a warning is given by the routine.

4. References

5. Parameters

1: M -- INTEGER Input
   On entry: the kind of functions required.
   (1)
   If M = 1, the functions are \( H^{(nu)}(z) \).
   (2)
   If M = 2, the functions are \( H^{(nu)}(z) \).
   Constraint: M = 1 or 2.

2: FNU -- DOUBLE PRECISION Input
   On entry: the order, \((\nu)\), of the first member of the sequence of functions. Constraint: FNU \(\geq 0.0\).
3:  Z -- COMPLEX(KIND(1.0DO))  Input
   On entry: the argument z of the functions. Constraint: Z /= (0.0, 0.0).

4:  N -- INTEGER  Input
   On entry: the number, N, of members required in the sequence
   (M)   (M)   (M)
   (nu)   (nu)+1   (nu)+N-1

5:  SCALE -- CHARACTER*1  Input
   On entry: the scaling option.
   If SCALE = 'U', the results are returned unscaled.
   If SCALE = 'S', the results are returned scaled by the
   -iz    iz
   factor e when M = 1, or by the factor e when M = 2.
   Constraint: SCALE = 'U' or 'S'.

6:  CY(N) -- COMPLEX(KIND(1.0D)) array  Output
   On exit: the N required function values: CY(i) contains
   (M)
   H , for i=1,2,...,N.
   (nu)+i-1

7:  NZ -- INTEGER  Output
   On exit: the number of components of CY that are set to zero
   due to underflow. If NZ > 0, then if Imz>0.0 and M = 1, or
   Imz<0.0 and M = 2, elements CY(1), CY(2),...,CY(NZ) are set
   to zero. In the complementary half-planes, NZ simply states
   the number of underflows, and not which elements they are.

8:  IFAIL -- INTEGER  Input/Output
   On entry: IFAIL must be set to 0, -1 or 1. For users not
   familiar with this parameter (described in the Essential
   Introduction) the recommended value is 0.

   On exit: IFAIL = 0 unless the routine detects an error (see
   Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
On entry M /= 1 and M /= 2, 
or FNU < 0.0, 
or Z = (0.0, 0.0), 
or N < 1, 
or SCALE /= 'U' or 'S'.

IFAIL= 2
No computation has been performed due to the likelihood of overflow, because ABS(Z) is less than a machine-dependent threshold value (given in the Users’ Note for your implementation).

IFAIL= 3
No computation has been performed due to the likelihood of overflow, because FNU + N - 1 is too large - how large depends on Z and the overflow threshold of the machine.

IFAIL= 4
The computation has been performed, but the errors due to argument reduction in elementary functions make it likely that the results returned by S17DLF are accurate to less than half of machine precision. This error exit may occur if either ABS(Z) or FNU + N - 1 is greater than a machine-dependent threshold value (given in the Users’ Note for your implementation).

IFAIL= 5
No computation has been performed because the errors due to argument reduction in elementary functions mean that all precision in results returned by S17DLF would be lost. This error exit may occur when either of ABS(Z) or FNU + N - 1 is greater than a machine-dependent threshold value (given in the Users’ Note for your implementation).

IFAIL= 6
No results are returned because the algorithm termination condition has not been met. This may occur because the parameters supplied to S17DLF would have caused overflow or underflow.

7. Accuracy

All constants in subroutine S17DLF are given to approximately 18 digits of precision. Calling the number of digits of precision in the floating-point arithmetic being used t, then clearly the maximum number of correct digits in the results obtained is
limited by \( p = \min(t, 18) \). Because of errors in argument reduction when computing elementary functions inside S17DLF, the actual number of correct digits is limited, in general, by \( p-s \), where \( s = \max(1, \log |z|, \log |\nu|) \) represents the number of digits lost due to the argument reduction. Thus the larger the values of \( |z| \) and \( |\nu| \), the less the precision in the result. If S17DLF is called with \( N > 1 \), then computation of function values via recurrence may lead to some further small loss of accuracy.

If function values which should nominally be identical are computed by calls to S17DLF with different base values of \( \nu \) and different \( N \), the computed values may not agree exactly. Empirical tests with modest values of \( \nu \) and \( z \) have shown that the discrepancy is limited to the least significant 3-4 digits of precision.

8. Further Comments

The time taken by the routine for a call of S17DLF is approximately proportional to the value of \( N \), plus a constant. In general it is much cheaper to call S17DLF with \( N \) greater than 1, rather than to make \( N \) separate calls to S17DLF.

Paradoxically, for some values of \( z \) and \( \nu \), it is cheaper to call S17DLF with a larger value of \( N \) than is required, and then discard the extra function values returned. However, it is not possible to state the precise circumstances in which this is likely to occur. It is due to the fact that the base value used to start recurrence may be calculated in different regions for different \( N \), and the costs in each region may differ greatly.

9. Example

The example program prints a caption and then proceeds to read sets of data from the input data stream. The first datum is a value for the kind of function, \( M \), the second is a value for the order \( \nu \), the third is a complex value for the argument, \( z \), and the fourth is a value for the parameter \( \text{SCALE} \). The program calls the routine with \( N = 2 \) to evaluate the function for orders \( \nu \) and \( \nu + 1 \), and it prints the results. The process is repeated until the end of the input data stream is encountered.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
Returns the value of the modified Bessel Function $K_0(x)$

--- nags.ht ---

\begin{verbatim}
S18ACF(3NAG) Foundation Library (12/10/92) S18ACF(3NAG)

S18 -- Approximations of Special Functions
S18ACF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S18ACF returns the value of the modified Bessel Function $K_0(x)$, via the routine name.

2. Specification

\begin{verbatim}
DOUBLE PRECISION FUNCTION S18ACF (X, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X
\end{verbatim}

3. Description

This routine evaluates an approximation to the modified Bessel Function of the second kind $K_0(x)$.

Note: $K_0(x)$ is undefined for $x \leq 0$ and the routine will fail for such arguments.

The routine is based on five Chebyshev expansions:
For $0 < x \leq 1$,
\[
K(x) = -\ln x = a_T(t) + b_T(t), \quad \text{where} \quad t = 2x - 1;
\]
\[
K(x) = -\ln x = a_T(t) + b_T(t), \quad \text{where} \quad t = 2x - 1;
\]
\[
R = 0 \quad R = 0
\]

For $1 < x \leq 2$,
\[
K(x) = e^{-c_T(t)} \quad \text{where} \quad t = 2x - 3;
\]
\[
R = 0
\]

For $2 < x \leq 4$,
\[
K(x) = e^{-d_T(t)} \quad \text{where} \quad t = x - 3;
\]
\[
R = 0
\]

For $x > 4$,
\[
K(x) = e^{-(\gamma) - \ln \left( \frac{9-x}{1+x} \right)} \quad \text{where} \quad (\gamma) = \text{Euler's constant.}
\]

For $x$ near zero, $K(x) \approx -\ln x$, where $\gamma$ denotes Euler's constant. This approximation is used when $x$ is sufficiently small for the result to be correct to machine precision.

For large $x$, where there is a danger of underflow due to the smallness of $K$, the result is set exactly to zero.

4. References

5. Parameters

1: X -- DOUBLE PRECISION
   Input
   On entry: the argument $x$ of the function. Constraint: $X > 0$. 0.
2: IFAIL -- INTEGER

On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL = 1
X <= 0.0, K is undefined. On soft failure the routine returns zero.

7. Accuracy

Let (delta) and (epsilon) be the relative errors in the argument and result respectively.

If (delta) is somewhat larger than the machine precision (i.e., if (delta) is due to data errors etc), then (epsilon) and (delta) are approximately related by:

\[
\frac{|xK(x)|}{K(x)} \approx \frac{| \epsilon |}{(\delta)}
\]

Figure 1 shows the behaviour of the error amplification factor

\[
\frac{|xK(x)|}{K(x)} \approx | \epsilon | (\delta)
\]

However, if (delta) is of the same order as machine precision, then rounding errors could make (epsilon) slightly larger than the above relation predicts.

\[
\frac{|1|}{|\ln x|}
\]

For small x, the amplification factor is approximately

\[
\frac{|1|}{|\ln x|}
\]
which implies strong attenuation of the error, but in general (epsilon) can never be less than the machine precision.

For large x, (epsilon)^x=x(delta) and we have strong amplification of the relative error. Eventually K, which is asymptotically

\[ K \approx \frac{\gamma}{x} \]

given by \( \frac{1}{x} \), becomes so small that it cannot be calculated without underflow and hence the routine will return zero. Note that for large x the errors will be dominated by those of the Fortran intrinsic function EXP.

8. Further Comments

For details of the time taken by the routine see the appropriate the Users’ Note for your implementation.

9. Example

The example program reads values of the argument x from a file, evaluates the function at each value of x and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
1. Purpose

S18ADF returns the value of the modified Bessel Function $K_1(x)$ via the routine name.

2. Specification

```plaintext
DOUBLE PRECISION FUNCTION S18ADF (X, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X
```

3. Description

This routine evaluates an approximation to the modified Bessel Function of the second kind $K_1(x)$.

Note: $K_1(x)$ is undefined for $x \leq 0$ and the routine will fail for such arguments.

The routine is based on five Chebyshev expansions:

For $0 < x \leq 1$,

$$K_1(x) = \frac{-x \ln x}{2} + \sum_{r=0}^{1} \frac{a_{2r}}{2^{2r}} T_{2r+1}(t),$$

where $t = 2x - 1$.

For $1 < x \leq 2$,

$$K_1(x) = e^{-x} \sum_{r=0}^{1} c_{2r} T_{2r}(t),$$

where $t = 2x - 3$.

For $2 < x \leq 4$, the expansion details are not provided in this text.
\[
K(x) = e^{\frac{-x}{r \cdot (t-x)}} , \text{ where } t=x-3;
\]
where \( r=0 \).

For \( x>4 \),
\[
K(x) = e^{\frac{-x}{r \cdot (t-x)}} , \text{ where } t=\frac{9-x}{1+x},
\]
where \( r=0 \).

For \( x \) near zero, \( K(x) \approx \frac{1}{x} \). This approximation is used when \( x \) is sufficiently small for the result to be correct to machine precision. For very small \( x \) on some machines, it is impossible to calculate \( \frac{1}{x} \) without overflow and the routine must fail.

For large \( x \), where there is a danger of underflow due to the smallness of \( K \), the result is set exactly to zero.

4. References

5. Parameters

1: X -- DOUBLE PRECISION
   On entry: the argument \( x \) of the function. Constraint: \( X > 0 \).

2: IFAIL -- INTEGER
   On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
   On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL = 1
X <= 0.0, K is undefined. On soft failure the routine returns zero.

IFAIL= 2
X is too small, there is a danger of overflow. On soft failure the routine returns approximately the largest representable value.

7. Accuracy

Let (delta) and (epsilon) be the relative errors in the argument and result respectively.

If (delta) is somewhat larger than the machine precision (i.e., if (delta) is due to data errors etc), then (epsilon) and (delta) are approximately related by:

\[
\frac{|xK(x) - K(x)|}{K(x)} \approx \frac{1}{\epsilon}(\delta).
\]

Figure 1 shows the behaviour of the error amplification factor

\[
\frac{|xK(x) - K(x)|}{K(x)} \approx \frac{1}{\epsilon}(\delta).
\]

However if (delta) is of the same order as the machine precision, then rounding errors could make (epsilon) slightly larger than the above relation predicts.

For small x, (epsilon)~=(delta) and there is no amplification of errors.

For large x, (epsilon)~=x(delta) and we have strong amplification of the relative error. Eventually K, which is asymptotically given by \(-\frac{x}{e}\) becomes so small that it cannot be calculated.
without underflow and hence the routine will return zero. Note that for large \( x \) the errors will be dominated by those of the Fortran intrinsic function EXP.

8. Further Comments

For details of the time taken by the routine see the Users’ Note for your implementation.

9. Example

The example program reads values of the argument \( x \) from a file, evaluates the function at each value of \( x \) and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

---

Returns the value of the modified Bessel Function \( I_0(x) \)

--- nags.ht ---

Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.
1. Purpose

S18AEF returns the value of the modified Bessel Function $I_0(x)$ via the routine name.

2. Specification

```fortran
DOUBLE PRECISION FUNCTION S18AEF (X, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X
```

3. Description

This routine evaluates an approximation to the modified Bessel function of the first kind $I_0(x)$.

Note: $I_0(-x)=I_0(x)$, so the approximation need only consider $x \geq 0$.

The routine is based on three Chebyshev expansions:

For $0 < x \leq 4$,

$$I_0(x) = e^{-x} \sum_{r=0}^{\infty} a_r (x/4)^r$$

For $4 < x \leq 12$,

$$I_0(x) = e^{-x+8} \sum_{r=0}^{\infty} b_r (x/4)^r$$

For $x > 12$,

$$I_0(x) = e^{-x}(12) \sum_{r=0}^{\infty} c_r (x/\sqrt{x})^r$$

For small $x$, $I_0(x) \approx 1$. This approximation is used when $x$ is sufficiently small for the result to be correct to machine precision.
For large $x$, the routine must fail because of the danger of $x$ overflow in calculating $e$.

4. References

5. Parameters

1: X -- DOUBLE PRECISION
   Input
   On entry: the argument $x$ of the function.

2: IFAIL -- INTEGER
   Input/Output
   On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
   On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
   X is too large. On soft failure the routine returns the approximate value of $I(x)$ at the nearest valid argument.

7. Accuracy

Let (delta) and (epsilon) be the relative errors in the argument and result respectively.

If (delta) is somewhat larger than the machine precision (i.e., if (delta) is due to data errors etc), then (epsilon) and (delta) are approximately related by:

$$\frac{|xI(x)|}{|I(x)|} \approx \frac{1}{(epsilon)}$$

Figure 1 shows the behaviour of the error amplification factor

$$\frac{|xI(x)|}{|I(x)|}$$
However if \( \delta \) is of the same order as machine precision, then rounding errors could make \( \epsilon \) slightly larger than the above relation predicts.

\[
\frac{2}{x}
\]

For small \( x \) the amplification factor is approximately \( \frac{2}{x} \), which implies strong attenuation of the error, but in general \( \epsilon \) can never be less than the machine precision.

For large \( x \), \( \epsilon \approx x \delta \) and we have strong amplification of errors. However the routine must fail for quite moderate values of \( x \), because \( I(x) \) would overflow; hence in practice the loss of accuracy for large \( x \) is not excessive. Note that for large \( x \) the errors will be dominated by those of the Fortran intrinsic function EXP.

8. Further Comments

For details of the time taken by the routine see the Users' Note for your implementation.

9. Example

The example program reads values of the argument \( x \) from a file, evaluates the function at each value of \( x \) and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
Returns a value for the modified Bessel Function $I_1(x)$
For $4 < x \leq 12$,

$$I(x) = e^{\frac{x}{4}} \left( \frac{x}{4} \right)$$

For $x > 12$,

$$I(x) = \frac{e^{2(\sqrt{x} - 1)}}{\sqrt{x}}$$

For small $x$, $I(x) \approx x$. This approximation is used when $x$ is sufficiently small for the result to be correct to machine precision.

For large $x$, the routine must fail because $I(x)$ cannot be represented without overflow.

4. References

5. Parameters

1: $X$ -- DOUBLE PRECISION
   Input
   On entry: the argument $x$ of the function.

2: $IFAIL$ -- INTEGER
   Input/Output
   On entry: $IFAIL$ must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

   On exit: $IFAIL = 0$ unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

$IFAIL = 1$
X is too large. On soft failure the routine returns the approximate value of I(x) at the nearest valid argument.

7. Accuracy

Let (delta) and (epsilon) be the relative errors in the argument and result respectively.

If (delta) is somewhat larger than the machine precision (i.e., if (delta) is due to data errors etc), then (epsilon) and (delta) are approximately related by:

\[
\frac{| xI(x) - I(x) |}{I(x)} \approx (\delta).
\]

Figure 1 shows the behaviour of the error amplification factor

\[
\frac{| xI(x) - I(x) |}{I(x)}.
\]

Please see figure in printed Reference Manual

However if (delta) is of the same order as machine precision, then rounding errors could make (epsilon) slightly larger than the above relation predicts.

For small x, (epsilon) ~(delta) and there is no amplification of errors.

For large x, (epsilon) ~ x(delta) and we have strong amplification of errors. However the routine must fail for quite moderate values of x because I(x) would overflow; hence in practice the loss of accuracy for large x is not excessive. Note that for large x, the errors will be dominated by those of the Fortran intrinsic function EXP.

8. Further Comments

For details of the time taken by the routine see the Users’ Note for your implementation.
9. Example

The example program reads values of the argument $x$ from a file, evaluates the function at each value of $x$ and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
3. Description

This subroutine evaluates a sequence of values for the modified Bessel function $K_n(z)$, where $z$ is complex, $-(\pi) < \arg z \leq (\pi)$, and $n$ is the real, non-negative order. The $N$-member sequence is generated for orders $n$, $n+1, \ldots, n+N-1$.

Optionally, the sequence is scaled by the factor $e^z$.

The routine is derived from the routine CBESK in Amos [2].

Note: although the routine may not be called with $n$ less than zero, for negative orders the formula $K_{-n}(z)=K_n(z)$ may be used.

When $N$ is greater than 1, extra values of $K_n(z)$ are computed using recurrence relations.

For very large $|z|$ or $(n+N-1)$, argument reduction will cause total loss of accuracy, and so no computation is performed. For slightly smaller $|z|$ or $(n+N-1)$, the computation is performed but results are accurate to less than half of machine precision. If $|z|$ is very small, near the machine underflow threshold, or $(n+N-1)$ is too large, there is a risk of overflow and so no computation is performed. In all the above cases, a warning is given by the routine.

4. References

5. Parameters

1: FNU -- DOUBLE PRECISION Input
On entry: the order, $n$, of the first member of the sequence of functions. Constraint: FNU $\geq 0.0$.

2: Z -- COMPLEX(KIND(1.D0)) Input
On entry: the argument $z$ of the functions. Constraint: $z \neq (0.0, 0.0)$.

3: $N$ -- INTEGER  
On entry: the number, $N$, of members required in the sequence $K(z), K(z), \ldots, K(z)$. Constraint: $N \geq 1$.

4: SCALE -- CHARACTER*1  
On entry: the scaling option.
- If SCALE = 'U', the results are returned unscaled.
- If SCALE = 'S', the results are returned scaled by the $z$ factor $e$. Constraint: SCALE = 'U' or 'S'.

5: CY(N) -- COMPLEX(KIND(1.0D)) array  
On exit: the $N$ required function values: CY(i) contains $K(z)$, for $i=1,2,\ldots,N$.

6: NZ -- INTEGER  
On exit: the number of components of CY that are set to zero due to underflow. If NZ > 0 and Rez>=0.0, elements CY(1), CY(2), \ldots, CY(NZ) are set to zero. If Rez<0.0, NZ simply states the number of underflows, and not which elements they are.

7: IFAIL -- INTEGER  
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IAFAIL = 1  
On entry FNU < 0.0,  
or $Z = (0.0, 0.0)$,  
or $N < 1$,
or \[ \text{SCALE} 
eq 'U' \text{ or } 'S'. \]

    IFAIL= 2
    No computation has been performed due to the likelihood of overflow, because \( \text{ABS}(Z) \) is less than a machine-dependent threshold value (given in the Users' Note for your implementation).

    IFAIL= 3
    No computation has been performed due to the likelihood of overflow, because \( FNU + N - 1 \) is too large - how large depends on \( Z \) and the overflow threshold of the machine.

    IFAIL= 4
    The computation has been performed, but the errors due to argument reduction in elementary functions make it likely that the results returned by S18DCF are accurate to less than half of machine precision. This error exit may occur if either \( \text{ABS}(Z) \) or \( FNU + N - 1 \) is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

    IFAIL= 5
    No computation has been performed because the errors due to argument reduction in elementary functions mean that all precision in results returned by S18DCF would be lost. This error exit may occur when either \( \text{ABS}(Z) \) or \( FNU + N - 1 \) is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

    IFAIL= 6
    No results are returned because the algorithm termination condition has not been met. This may occur because the parameters supplied to S18DCF would have caused overflow or underflow.

7. Accuracy

All constants in subroutine S18DCF are given to approximately 18 digits of precision. Calling the number of digits of precision in the floating-point arithmetic being used \( t \), then clearly the maximum number of correct digits in the results obtained is limited by \( p = \min(t,18) \). Because of errors in argument reduction when computing elementary functions inside S18DCF, the actual number of correct digits is limited, in general, by \( p - s \), where \( s = \max(1, \log_{10} |z|, |\log_{10} (nu)|) \) represents the number of digits lost due to the argument reduction. Thus the larger the values of
If \(|z|\) and \((\nu)\), the less the precision in the result. If \(S18DCF\) is called with \(N>1\), then computation of function values via recurrence may lead to some further small loss of accuracy.

If function values which should nominally be identical are computed by calls to \(S18DCF\) with different base values of \((\nu)\) and different \(N\), the computed values may not agree exactly. Empirical tests with modest values of \((\nu)\) and \(z\) have shown that the discrepancy is limited to the least significant 3-4 digits of precision.

8. Further Comments

The time taken by the routine for a call of \(S18DCF\) is approximately proportional to the value of \(N\), plus a constant. In general it is much cheaper to call \(S18DCF\) with \(N\) greater than 1, rather than to make \(N\) separate calls to \(S18DCF\).

Paradoxically, for some values of \(z\) and \((\nu)\), it is cheaper to call \(S18DCF\) with a larger value of \(N\) than is required, and then discard the extra function values returned. However, it is not possible to state the precise circumstances in which this is likely to occur. It is due to the fact that the base value used to start recurrence may be calculated in different regions for different \(N\), and the costs in each region may differ greatly.

Note that if the function required is \(K(x)\) or \(K'(x)\), i.e., \((\nu)=0.0\) or \(1.0\), where \(x\) is real and positive, and only a single function value is required, then it may be much cheaper to call \(S18ACF\), \(S18ADF\), \(S18CCF(*)\) or \(S18CDF(*)\), depending on whether a scaled result is required or not.

9. Example

The example program prints a caption and then proceeds to read sets of data from the input data stream. The first datum is a value for the order \(\nu\), the second is a complex value for the argument, \(z\), and the third is a value for the parameter \(SCALE\). The program calls the routine with \(N=2\) to evaluate the function for orders \(\nu\) and \(\nu+1\), and it prints the results. The process is repeated until the end of the input data stream is encountered.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
Sequence of values for the modified Bessel $I_{\nu+n}$
sequence is generated for orders $(\nu)$, $(\nu)+1, \ldots, (\nu)+N-1$.

Optionally, the sequence is scaled by the factor $e^{-|\text{Re}(z)|}$.

The routine is derived from the routine CBESI in Amos [2].

Note: although the routine may not be called with $(\nu)$ less than zero, for negative orders the formula

$$I_{\nu}(z) = I_{\nu}(z) + \frac{e^{-|\pi\nu|}}{\sin(\pi\nu)}K_{\nu}(z)$$

may be used (for $-\nu$, $\nu$, $\pi$, $\nu$ the Bessel function $K_{\nu}(z)$, see S18DCF).

When $N$ is greater than 1, extra values of $I_{\nu}(z)$ are computed using recurrence relations.

For very large $|z|$ or $(\nu)+N-1$, argument reduction will cause total loss of accuracy, and so no computation is performed. For slightly smaller $|z|$ or $(\nu)+N-1$, the computation is performed but results are accurate to less than half of machine precision. If $\text{Re}(z)$ is too large and the unscaled function is required, there is a risk of overflow and so no computation is performed. In all the above cases, a warning is given by the routine.

4. References

5. Parameters

1: FNU -- DOUBLE PRECISION
   On entry: the order, $(\nu)$, of the first member of the sequence of functions. Constraint: $FNU \geq 0.0$.

2: Z -- COMPLEX(KIND(1.0D0))
   On entry: the argument $z$ of the functions.

3: N -- INTEGER
   On entry: the number, $N$, of members required in the sequence $I_{\nu}(z), I_{\nu}(z), \ldots, I_{\nu}(z)$. Constraint: $N \geq 1$.

4: SCALE -- CHARACTER*1
On entry: the scaling option.
    If SCALE = 'U', the results are returned unscaled.

    If SCALE = 'S', the results are returned scaled by the
    factor e^{-\|Rez\|}.

Constraint: SCALE = 'U' or 'S'.

5: CY(N) -- COMPLEX(KIND(1.0D)) array
On exit: the N required function values: CY(i) contains
    I_\nu(z), for i=1,2,...,N.
    (nu)+i-1

6: NZ -- INTEGER
On exit: the number of components of CY that are set to zero
    due to underflow.

    If NZ > 0, then elements CY(N-NZ+1),CY(N-NZ+2),...,CY(N) are
    set to zero.

7: IFAIL -- INTEGER
On entry: IFAIL must be set to 0, -1 or 1. For users not
    familiar with this parameter (described in the Essential
    Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see
    Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
output on the current error message unit (as defined by X04AAF).

IFAIL= 1
On entry FNU < 0.0,
    or N < 1,
    or SCALE /= 'U' or 'S'.

IFAIL= 2
No computation has been performed due to the likelihood of
overflow, because real(Z) is greater than a machine-
dependent threshold value (given in the Users' Note for
your implementation). This error exit can only occur when
SCALE = 'U'.

IFAIL= 3
The computation has been performed, but the errors due to argument reduction in elementary functions make it likely that the results returned by S18DEF are accurate to less than half of machine precision. This error exit may occur when either ABS(Z) or FNU + N - 1 is greater than a machine-dependent threshold value (given in the Users’ Note for your implementation).

IFAIL = 4
No computation has been performed because the errors due to argument reduction in elementary functions mean that all precision in results returned by S18DEF would be lost. This error exit may occur when either ABS(Z) or FNU + N - 1 is greater than a machine-dependent threshold value (given in the Users’ Note for your implementation).

IFAIL = 5
No results are returned because the algorithm termination condition has not been met. This may occur because the parameters supplied to S18DEF would have caused overflow or underflow.

7. Accuracy

All constants in subroutine S18DEF are given to approximately 18 digits of precision. Calling the number of digits of precision in the floating-point arithmetic being used t, then clearly the maximum number of correct digits in the results obtained is limited by $p = \min(t, 18)$. Because of errors in argument reduction when computing elementary functions inside S18DEF, the actual number of correct digits is limited, in general, by $p - s$, where $s = \max(1, |\log |z||, |\log (\nu)||, |\log (\nu)|)$ represents the number of digits lost due to the argument reduction. Thus the larger the values of $|z|$ and $(\nu)$, the less the precision in the result. If S18DEF is called with $N > 1$, then computation of function values via recurrence may lead to some further small loss of accuracy.

If function values which should nominally be identical are computed by calls to S18DEF with different base values of $(\nu)$ and different $N$, the computed values may not agree exactly. Empirical tests with modest values of $(\nu)$ and $z$ have shown that the discrepancy is limited to the least significant 3-4 digits of precision.

8. Further Comments

The time taken by the routine for a call of S18DEF is approximately proportional to the value of $N$, plus a constant. In general it is much cheaper to call S18DEF with $N$ greater than 1,
rather than to make \( N \) separate calls to S18DEF.

Paradoxically, for some values of \( z \) and \( \nu \), it is cheaper to call S18DEF with a larger value of \( N \) than is required, and then discard the extra function values returned. However, it is not possible to state the precise circumstances in which this is likely to occur. It is due to the fact that the base value used to start recurrence may be calculated in different regions for different \( N \), and the costs in each region may differ greatly.

Note that if the function required is \( I_0(x) \) or \( I_1(x) \), i.e.,

\[
\begin{array}{c|c}
0 & 1 \\
\hline
\nu = 0.0 & 1.0
\end{array}
\]

where \( x \) is real and positive, and only a single function value is required, then it may be much cheaper to call S18AEF, S18AFF, S18CEF(*) or S18CFF(*), depending on whether a scaled result is required or not.

9. Example

The example program prints a caption and then proceeds to read sets of data from the input data stream. The first datum is a value for the order FNU, the second is a complex value for the argument, Z, and the third is a value for the parameter SCALE. The program calls the routine with \( N = 2 \) to evaluate the function for orders FNU and FNU + 1, and it prints the results. The process is repeated until the end of the input data stream is encountered.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

---

Returns a value for the Kelvin function \( \text{ber} \ x \)
S19AAF returns a value for the Kelvin function $\text{ber} x$ via the routine name.

2. Specification

```fortran
DOUBLE PRECISION FUNCTION S19AAF (X, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X
```

3. Description

This routine evaluates an approximation to the Kelvin function $\text{ber} x$.

Note: $\text{ber}(-x) = \text{ber} x$, so the approximation need only consider $x \geq 0.0$.

The routine is based on several Chebyshev expansions:

For $0 \leq x < 5$,

\[
\text{ber} x = \sum_{r=0}^{\infty} \frac{(-x)^{4r}}{2^r r!^2} T_r(\tan^{-1}\frac{1}{2x})
\]

For $x > 5$,

\[
\text{ber} x = \frac{e^{-x/\sqrt{2}}}{\sqrt{\pi}x} \left[ (1 - a(t))\cos(\alpha) + b(t)\sin(\alpha) \right]
\]

where

\[
a(t) = \left[ \begin{array}{c} 1 \\ 1 \end{array} \right] \\
b(t) = \left[ \begin{array}{c} 1 \\ x \end{array} \right]
\]

and

\[
\alpha = \arctan(\frac{1}{2x})
\]

\[
t = \tan(\alpha/2)
\]

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.
\[ -x^{\sqrt{2}} e^{\left( \begin{array}{c} 1 \\ 1 \end{array} \right) \sin(\beta) + \frac{1}{x} \left( 1+ \frac{c(t)}{a(t)} \right) \sin(\beta) + \frac{1}{x} \left( 1+ \frac{d(t)}{a(t)} \right) \cos(\beta)} \] \]

where \( \alpha = \frac{1}{\sqrt{2}}, \beta = \frac{\pi}{8}, \)

and \( a(t), b(t), c(t), \) and \( d(t) \) are expansions in the variable \( t = \frac{1}{x(1+\frac{c(t)}{a(t)})}. \)

When \( x \) is sufficiently close to zero, the result is set directly to \( 0 = 1.0. \)

For large \( x \), there is a danger of the result being totally inaccurate, as the error amplification factor grows in an essentially exponential manner; therefore the routine must fail.

4. References

5. Parameters

1: \( X \quad \text{-- DOUBLE PRECISION} \quad \text{Input} \)
   On entry: the argument \( x \) of the function.

2: \( IFAIL \quad \text{-- INTEGER} \quad \text{Input/Output} \)
   On entry: \( IFAIL \) must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

   On exit: \( IFAIL = 0 \) unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

\( IFAIL = 1 \)

On entry \( \text{ABS}(X) \) is too large for an accurate result to be
7. Accuracy

Since the function is oscillatory, the absolute error rather than the relative error is important. Let \( E \) be the absolute error in the result and \( \delta \) be the relative error in the argument. If \( \delta \) is somewhat larger than the machine precision, then we have:

\[
| x | E = | \frac{|\text{ber} x + \text{bei} x|}{\delta} |
\]

\[
| 1 | 1 | \\
| \sqrt{2} | \\
\]

(provided \( E \) is within machine bounds).

For small \( x \) the error amplification is insignificant and thus the absolute error is effectively bounded by the machine precision.

For medium and large \( x \), the error behaviour is oscillatory and

\[
\frac{x}{\sqrt{2}} x/\sqrt{2}
\]

its amplitude grows like \( \sqrt{\frac{x}{2\pi}} \). Therefore it is not possible to calculate the function with any accuracy when

\[
\frac{x}{\sqrt{2}} /2(\pi) \\
\sqrt{x} > \text{------} \delta
\]

the minimum value of \( x \) for which the function overflows.

8. Further Comments

For details of the time taken by the routine see the Users’ Note for your implementation.

9. Example

The example program reads values of the argument \( x \) from a file, evaluates the function at each value of \( x \) and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

\]

bei $x = \frac{1}{\sqrt{2}}[(1 - a(t))\sin(\alpha) - b(t)\cos(\alpha)]$

\[
\frac{x}{2}\pi
\]

\[
[(x)^{2} - x] 
\]

\[
\sqrt{2}\pi
\]

where $(\alpha)$ = \frac{\pi}{8}, $(\beta)$ = \frac{\pi}{8},

\[
\sqrt{2}
\]

and $a(t)$, $b(t)$, $c(t)$, and $d(t)$ are expansions in the variable $t = \frac{1}{x}$.

When $x$ is sufficiently close to zero, the result is computed as

\[
2 \quad x \quad (x)^{4}
\]

bei $x = \rightarrow$. If this result would underflow, the result returned is

\[
4 \quad beix = 0.0.
\]

For large $x$, there is a danger of the result being totally inaccurate, as the error amplification factor grows in an essentially exponential manner; therefore the routine must fail.

4. References
5. Parameters

1: X -- DOUBLE PRECISION Input
On entry: the argument x of the function.

2: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not
familiar with this parameter (described in the Essential
Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see
Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
On entry ABS(X) is too large for an accurate result to be
returned. On soft failure, the routine returns zero.

7. Accuracy

Since the function is oscillatory, the absolute error rather than
the relative error is important. Let E be the absolute error in
the function, and (delta) be the relative error in the argument.
If (delta) is somewhat larger than the machine precision, then we
have:

\[ E \approx \frac{\text{abs}(\text{ber} x + \text{bei} x)}{\sqrt{2}} \times (\text{delta}) \]

(provided E is within machine bounds).

For small x the error amplification is insignificant and thus the
absolute error is effectively bounded by the machine precision.

For medium and large x, the error behaviour is oscillatory and

\[ \frac{x}{\sqrt{2}} \]

its amplitude grows like \[ \frac{\text{e}^{-x}}{2\pi} \]. Therefore it is
impossible to calculate the functions with any accuracy when
\[ \frac{x}{\sqrt{2}} / (2\pi) \]
\[
/xe > \text{delta}. \text{Note that this value of } x \text{ is much smaller than the minimum value of } x \text{ for which the function overflows.}
\]

8. Further Comments

For details of the time taken by the routine see the Users’ Note for your implementation.

9. Example

The example program reads values of the argument \( x \) from a file, evaluates the function at each value of \( x \) and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

---

Returns a value for the Kelvin function \( \mathrm{ker} \ x \)

— nags.ht —

\[ \text{S19ACF}(3\text{NAG}) \quad \text{Foundation Library (12/10/92)} \quad \text{S19ACF}(3\text{NAG}) \]

\[ \text{S19} -- \text{Approximations of Special Functions} \quad \text{S19ACF} \]
\[ \text{S19ACF} -- \text{NAG Foundation Library Routine Document} \]

Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is
not included in the Foundation Library.

1. Purpose

S19ACF returns a value for the Kelvin function \( \ker x \), via the routine name.

2. Specification

\[
\text{DOUBLE PRECISION FUNCTION S19ACF (X, IFAIL)}
\]

\[
\text{INTEGER IFAIL}
\]

\[
\text{DOUBLE PRECISION X}
\]

3. Description

This routine evaluates an approximation to the Kelvin function \( \ker x \).

Note: for \( x < 0 \) the function is undefined and at \( x = 0 \) it is infinite so we need only consider \( x > 0 \).

The routine is based on several Chebyshev expansions:

For \( 0 < x \leq 1 \),

\[
(\pi) \frac{2}{16} \ker x = f(t) \log x + \frac{x g(t) + y(t)}{16}
\]

where \( f(t) \), \( g(t) \) and \( y(t) \) are expansions in the variable \( t = 2x - 1 \);

For \( 1 < x \leq 3 \),

\[
(11) \exp(-x)q(t)
\]

where \( q(t) \) is an expansion in the variable \( t = x - 2 \);

For \( x > 3 \),

\[
-x^{-\sqrt{2}} \exp(\gamma) \left[ (1+\gamma^2)\cos(\beta)-\gamma \sin(\beta) \right]
\]

where \( \gamma \) is an expansion in the variable \( t = \sqrt{2x} \).
\[ \frac{x}{\pi} \]

where \( \beta \) = \( \frac{-\gamma}{\pi} - \frac{1}{8} \), and \( c(t) \) and \( d(t) \) are expansions in the variable \( t = \frac{1}{\sqrt{2}} x \).

When \( x \) is sufficiently close to zero, the result is computed as

\[ \frac{2}{\pi} \log(1 + x) \]

and when \( x \) is even closer to zero, simply as

\[ -\gamma - \log(1 - x) \]

For large \( x \), \( \ker x \) is asymptotically given by

\[ \frac{1}{\sqrt{2 \pi x}} \]

this becomes so small that it cannot be computed without underflow and the routine fails.

4. References

5. Parameters

1: \( X \) -- DOUBLE PRECISION Input
   On entry: the argument \( x \) of the function. Constraint: \( X > 0. \)

2: IFAIL -- INTEGER Input/Output
   On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
   On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:
IFAIL= 1
On entry X is too large, the result underflows. On soft
failure, the routine returns zero.

IFAIL= 2
On entry X <= 0, the function is undefined. On soft failure
the routine returns zero.

7. Accuracy

Let E be the absolute error in the result, (epsilon) be the
relative error in the result and (delta) be the relative error in
the argument. If (delta) is somewhat larger than the machine
precision, then we have:

\[
\begin{vmatrix}
| x | \\
\| E^- \|=| \frac{\operatorname{ker} x+\operatorname{kei} x}{\sqrt{2}} (\delta), \\
| 1 | \\
| \sqrt{2} | \\
\end{vmatrix}
\]

\[
\begin{vmatrix}
| \operatorname{ker} x+\operatorname{kei} x | \\
| x | \\
| \sqrt{2} | \\
\end{vmatrix}
\]

(epsilon)^\sim\|=| \frac{\sqrt{2}}{\operatorname{ker} x} (\delta).

For very small x, the relative error amplification factor is
approximately given by \frac{1}{\log x}, which implies a strong
attenuation of relative error. However, (epsilon) in general
cannot be less than the machine precision.

For small x, errors are damped by the function and hence are
limited by the machine precision.

For medium and large x, the error behaviour, like the function
itself, is oscillatory, and hence only the absolute accuracy for
the function can be maintained. For this range of x, the

\[
\frac{\pi x}{x-\sqrt{2}} / \approx \pi / \sqrt{2}
\]

amplitude of the absolute error decays like \frac{\pi x}{x-\sqrt{2}} / \approx \pi / \sqrt{2}

which implies a strong attenuation of error. Eventually, ker x,
which asymptotically behaves like $\frac{1}{\sqrt{2x}} e^{-x}$, becomes so small that it cannot be calculated without causing underflow, and the routine returns zero. Note that for large $x$ the errors are dominated by those of the Fortran intrinsic function EXP.

8. Further Comments

Underflow may occur for a few values of $x$ close to the zeros of $\text{ker} x$, below the limit which causes a failure with IFAIL = 1.

9. Example

The example program reads values of the argument $x$ from a file, evaluates the function at each value of $x$ and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
1. Purpose

S19ADF returns a value for the Kelvin function keix via the routine name.

2. Specification

```plaintext
DOUBLE PRECISION FUNCTION S19ADF (X, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X
```

3. Description

This routine evaluates an approximation to the Kelvin function keix.

Note: for x<0 the function is undefined, so we need only consider x>=0.

The routine is based on several Chebyshev expansions:

For 0<=x<=1,

\[
keix = \frac{2}{\pi} x \left(-\frac{1}{4f(t)} + \frac{1}{4g(t)\log x + v(t)}\right)
\]

where f(t), g(t) and v(t) are expansions in the variable t=2x - 1;

For 1<x<=3,

\[
keix = \exp(-\frac{9}{x})u(t)
\]

where u(t) is an expansion in the variable t=x-2;

For x>3,

\[
keix = \frac{\sqrt{\pi}}{2x} \left[(1+\frac{\sin(\beta)}{x})\cos(\beta) + \frac{\cos(\beta)}{x}\right]
\]

x (\pi)
where (beta)= ---+ ----, and c(t) and d(t) are expansions in the
8
\\[ t = \frac{\sqrt{2}}{6} \] variable t= --1.

For x<0, the function is undefined, and hence the routine fails and returns zero.

When x is sufficiently close to zero, the result is computed as

\[
keix = -\frac{2}{4} \pi \left( x \right) + \left( 1 - (\gamma) \log(-) \right) \frac{1}{4} (2)^4
\]

and when x is even closer to zero simply as

\[
keix = -\frac{\pi}{4}.
\]

For large x, keix is asymptotically given by

\[
keix = -\frac{\pi}{\sqrt{2x}} e
\]

this becomes so small that it cannot be computed without underflow and the routine fails.

4. References

5. Parameters

1: X -- DOUBLE PRECISION Input
   On entry: the argument x of the function. Constraint: X >= 0.

2: IFAIL -- INTEGER Input/Output
   On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
   On exit: IFAIL = 0 unless the routine detects an error (see Section 6).
6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
On entry X is too large, the result underflows. On soft failure, the routine returns zero.

IFAIL= 2
On entry X < 0, the function is undefined. On soft failure the routine returns zero.

7. Accuracy

Let E be the absolute error in the result, and (delta) be the relative error in the argument. If (delta) is somewhat larger than the machine representation error, then we have:

\[ |x| \frac{E}{E} \approx -\frac{-\text{ker} x + \text{kei} x}{1 - \frac{x}{\sqrt{2}}} (\text{delta}). \]

For small x, errors are attenuated by the function and hence are limited by the machine precision.

For medium and large x, the error behaviour, like the function itself, is oscillatory and hence only absolute accuracy of the function can be maintained. For this range of x, the amplitude of

\[ \frac{1}{(\pi) x} \frac{-x}{\sqrt{2}} \]

the absolute error decays like \[ \frac{-----e}{2} \], which implies a strong attenuation of error. Eventually, \text{kei} x, which is

\[ \frac{1}{(\pi) -x/\sqrt{2}} \]

asymptotically given by \[ \frac{-----e}{2x} \], becomes so small that it cannot be calculated without causing underflow and therefore the routine returns zero. Note that for large x, the errors are dominated by those of the Fortran intrinsic function EXP.

8. Further Comments

Underflow may occur for a few values of x close to the zeros of
keix, below the limit which causes a failure with IFAIL = 1.

9. Example

The example program reads values of the argument x from a file, evaluates the function at each value of x and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

---

Returns a value for the Fresnel Integral $S(x)$

--- nags.ht ---

---

S20ACF returns a value for the Fresnel Integral $S(x)$, via the routine name.

2. Specification

    DOUBLE PRECISION FUNCTION S20ACF (X, IFAIL)
    INTEGER IFAIL

DOUBLE PRECISION X

3. Description

This routine evaluates an approximation to the Fresnel Integral

\[ S(x) = \int_0^x \frac{\sin \left( \frac{\pi}{2} t \right)}{\sqrt{\pi}} \, dt. \]

Note: \( S(x) = -S(-x) \), so the approximation need only consider \( x \geq 0.0 \).

The routine is based on three Chebyshev expansions:

For \( 0 < x \leq 3 \),

\[ S(x) = x \left[ a \sum_{r=0}^{3} \frac{b_r}{x^r} \right], \quad \text{with} \quad t = 2(1 - x) - 1. \]

For \( x > 3 \),

\[ S(x) = \frac{1}{\sqrt{2\pi}} \left[ \cos \left( \frac{\pi}{2} x \right) - \frac{1}{3} \sin \left( \frac{\pi}{2} x \right) \right], \quad 2 \leq x \leq 3. \]

where \( f(x) = \sum_{r=0}^{3} \frac{b_r}{x^r} \),

and \( g(x) = \sum_{r=0}^{3} \frac{c_r}{x^r} \), with \( t = 2(1 - x) - 1 \).

For small \( x \), \( S(x) \approx \frac{1}{\sqrt{6}} x \). This approximation is used when \( x \) is sufficiently small for the result to be correct to machine precision. For very small \( x \), this approximation would underflow; the result is then set exactly to zero.

For large \( x \), \( f(x)^* = \frac{1}{\sqrt{2\pi}} \) and \( g(x)^* = \frac{1}{3} \). Therefore for \( x \geq 3 \),
moderately large $x$, when $\frac{1}{\pi x}$ is negligible compared with $\frac{1}{2}$, the second term in the approximation for $x>3$ may be dropped. For very large $x$, when $\frac{1}{\pi x}$ becomes negligible, $S(x) \approx -\frac{1}{2}$. However there will be considerable difficulties in calculating $\cos\left(\frac{\pi}{2}x\right)$ accurately before this final limiting value can be used. Since $\cos\left(\frac{\pi}{2}x\right)$ is periodic, its value is essentially determined by the fractional part of $x$. If $x = N + \theta$ where $N$ is an integer and $0 \leq \theta < 1$, then $\cos\left(\frac{\pi}{2}x\right)$ depends on $\theta$ and on $N$ modulo 4. By exploiting this fact, it is possible to retain significance in the calculation of $\cos\left(\frac{\pi}{2}x\right)$ either all the way to the very large $x$ limit, or at least until the integer part of $x$ is equal to the maximum integer allowed on the machine.

4. References

5. Parameters

1: $X$ -- DOUBLE PRECISION  
   Input 
   On entry: the argument $x$ of the function.

2: $IFAIL$ -- INTEGER  
   Input/Output 
   On entry: $IFAIL$ must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0. 
   On exit: $IFAIL = 0$ unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings
There are no failure exits from this routine. The parameter IFAIL has been included for consistency with other routines in this chapter.

7. Accuracy

Let (delta) and (epsilon) be the relative errors in the argument and result respectively.

If (delta) is somewhat larger than the machine precision (i.e., if (delta) is due to data errors etc), then (epsilon) and (delta) are approximately related by:

\[
| (\pi/2) |
|------------------|------------------|
| x \sin(\pi/2 - x ) |
| ( 2 ) |
\]

\[
(\text{epsilon}) \approx \frac{| \pi/2 |}{| S(x) |} (\text{delta}).
\]

Figure 1 shows the behaviour of the error amplification factor

\[
<table>
<thead>
<tr>
<th>\pi/2</th>
</tr>
</thead>
<tbody>
<tr>
<td>x \sin(\pi/2 - x )</td>
</tr>
<tr>
<td>( 2 )</td>
</tr>
</tbody>
</table>
\]

\[
| \text{epsilon} | \approx \frac{| \pi/2 |}{| S(x) |} (\text{delta}).
\]

However if (delta) is of the same order as the machine precision, then rounding errors could make (epsilon) slightly larger than the above relation predicts.

For small x, \((\text{epsilon}) \approx 3(\text{delta})\) and hence there is only moderate amplification of relative error. Of course for very small x where the correct result would underflow and exact zero is returned, relative error-control is lost.

For moderately large values of x,

\[
<table>
<thead>
<tr>
<th>(\pi/2)</th>
</tr>
</thead>
<tbody>
<tr>
<td>2x \sin(\pi/2 - x )</td>
</tr>
<tr>
<td>( 2 )</td>
</tr>
</tbody>
</table>
\]

\[
|(\text{epsilon})| \approx 2 |x \sin(\pi/2 - x )| (\text{delta}).
\]

and the result will be subject to increasingly large amplification of errors. However the above relation breaks down
for large values of $x$ (i.e., when \( \frac{2}{x} \) is of the order of the
\( \frac{2}{x} \) machine precision in this region the relative error in the result
\( \frac{2}{x} \) is essentially bounded by \( \frac{(\pi)x}{2} \).
\( \frac{(\pi)x}{2} \)

Hence the effects of error amplification are limited and at worst
the relative error loss should not exceed half the possible
number of significant figures.

8. Further Comments
None.

9. Example
The example program reads values of the argument $x$ from a file,
evaluates the function at each value of $x$ and prints the results.

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.
Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S20ADF returns a value for the Fresnel Integral C(x), via the routine name.

2. Specification

```fortran
DOUBLE PRECISION FUNCTION S20ADF (X, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X
```

3. Description

This routine evaluates an approximation to the Fresnel Integral

\[
C(x) = \int_0^x \frac{\cos \left( \frac{t}{(\pi)^2} \right)}{t} \, dt.
\]

Note: C(x) = -C(-x), so the approximation need only consider x \geq 0.0

The routine is based on three Chebyshev expansions:

For 0 < x \leq 3,

\[
C(x) = \sum_{r=0}^{\text{---}} a_r T_r(t), \quad \text{with } t = 2(-)^r - 1;
\]

For x > 3,

\[
C(x) = \frac{1}{2} f(x) \left( \frac{\pi}{2} \right) + g(x) \left( \frac{\pi}{2} \right)
\]

\[
+ \frac{1}{x} \sum_{r=0}^{\text{---}} b_r T_r(t),
\]

where \( f(x) = \sum_{r=0}^{\text{---}} \),

\[
+ \frac{1}{x} \sum_{r=0}^{\text{---}} \frac{1}{x} \sum_{r=0}^{\text{---}}
\]

\[
\text{where } f(x) = \sum_{r=0}^{\text{---}} \frac{1}{x} \sum_{r=0}^{\text{---}} \]
and \( g(x) = > c T(t) \), with \( t = 2( -)^{-1} \).
\[
\begin{array}{c}
\text{For small } x, C(x) = x. \text{ This approximation is used when } x \text{ is sufficiently small for the result to be correct to machine precision.}
\end{array}
\]
\[
\begin{array}{c}
\text{For large } x, \frac{1}{\pi} = \frac{1}{2} \text{ and } \frac{g(x)}{\pi} = \frac{1}{2}. \text{ Therefore for }
\end{array}
\]
\[
\begin{array}{c}
\text{moderately large } x, \text{ when } \frac{1}{2} \text{ is negligible compared with } - \frac{3}{2},
\end{array}
\]
\[
\begin{array}{c}
\text{the second term in the approximation for } x > 3 \text{ may be dropped. For very large } x, \text{ when } \frac{1}{2} \text{ becomes negligible, } C(x) = \frac{1}{2}. \text{ However}
\end{array}
\]
\[
\begin{array}{c}
\text{there will be considerable difficulties in calculating}
\end{array}
\]
\[
\begin{array}{c}

\text{sin( } \frac{\pi}{2} \text{ ) either all the way to the very large } x \text{ limit, or at least until the integer part of } \frac{x}{2} \text{ is equal to the maximum integer allowed on the machine.}
\end{array}
\]

4. References

5. Parameters
1:  X -- DOUBLE PRECISION                   Input
       On entry: the argument x of the function.

2:  IFAIL -- INTEGER            Input/Output
       On entry: IFAIL must be set to 0, -1 or 1. For users not
               familiar with this parameter (described in the Essential
               Introduction) the recommended value is 0.
       On exit: IFAIL = 0 unless the routine detects an error (see
               Section 6).

6. Error Indicators and Warnings

There are no failure exits from this routine. The parameter IFAIL
has been included for consistency with other routines in this
chapter.

7. Accuracy

Let (delta) and (epsilon) be the relative errors in the argument
and result respectively.

If (delta) is somewhat larger than the machine precision (i.e if
(delta) is due to data errors etc), then (epsilon) and (delta)
are approximately related by:

\[ (epsilon) \approx \frac{(pi)^2}{x \cos\left(\frac{x}{2}\right)} \cdot \frac{(2\times\delta)}{C(x)} \]

Figure 1 shows the behaviour of the error amplification factor

\[ \frac{(pi)^2}{x \cos\left(\frac{x}{2}\right)} \cdot \frac{(2\times\delta)}{C(x)} \]

However if (delta) is of the same order as the machine precision,
then rounding errors could make (epsilon) slightly larger than
the above relation predicts.

For small x, (epsilon)\approx(\delta) and there is no amplification of
relative error.
For moderately large values of $x$,

\[ | (\pi)^2 | \approx |2\pi\epsilon| \approx 2\pi x \cos \left( \frac{\epsilon}{2} x \right) |(\delta)| \]

and the result will be subject to increasingly large amplification of errors. However the above relation breaks down for large values of $x$ (i.e., when $\frac{\epsilon}{2}$ is of the order of the machine precision); in this region the relative error in the result is essentially bounded by $\frac{\epsilon}{(\pi)x}$.

Hence the effects of error amplification are limited and at worst the relative error loss should not exceed half the possible number of significant figures.

8. Further Comments

None.

9. Example

The example program reads values of the argument $x$ from a file, evaluates the function at each value of $x$ and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
S21 -- Approximations of Special Functions
S21BAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S21BAF returns a value of an elementary integral, which occurs as a degenerate case of an elliptic integral of the first kind, via the routine name.

2. Specification

```
DOUBLE PRECISION FUNCTION S21BAF (X, Y, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X, Y
```

3. Description

This routine calculates an approximate value for the integral

\[
R(x,y) = \int_{0}^{\infty} \frac{1}{\sqrt{t+x(t+y)}} dt
\]

where \( x \geq 0 \) and \( y > 0 \).

This function, which is related to the logarithm or inverse hyperbolic functions for \( y < x \) and to inverse circular functions if \( x < y \), arises as a degenerate form of the elliptic integral of the first kind. If \( y < 0 \), the result computed is the Cauchy principal value of the integral.

The basic algorithm, which is due to Carlson [2] and [3], is to reduce the arguments recursively towards their mean by the system:

\[
x = x,
\]
\[ y = y_0 \]
\[ (\mu) = (x + 2y_0) / 3, \]
\[ S = (y - x_0) / 3(\mu) \]
\[ (\lambda) = y + 2 / (x + y_0) \]
\[ x = (x + (\lambda)) / 4, \]
\[ y = (y + (\lambda)) / 4. \]

The quantity \(|S_n|\) for \(n=0,1,2,3,\ldots\) decreases with increasing \(n\), eventually \(|S_n| \sim 1/4\). For small enough \(S\) the required function value can be approximated by the first few terms of the Taylor series about the mean. That is
\[
R(x,y) = (1 + \frac{S}{3} + \frac{3S}{3} + \frac{9S}{9} + \ldots) / (\mu). 
\]

The truncation error involved in using this approximation is bounded by \(16|S| / (1 - 2|S|)\) and the recursive process is stopped when \(S\) is small enough for this truncation error to be negligible compared to the machine precision.

Within the domain of definition, the function value is itself representable for all representable values of its arguments. However, for values of the arguments near the extremes the above algorithm must be modified so as to avoid causing underflows or overflows in intermediate steps. In extreme regions arguments are pre-scaled away from the extremes and compensating scaling of the
result is done before returning to the calling program.

4. References

5. Parameters

1: X -- DOUBLE PRECISION Input

2: Y -- DOUBLE PRECISION Input
   On entry: the arguments x and y of the function, respectively. Constraint: X >= 0.0 and Y /= 0.0.

3: IFAIL -- INTEGER Input/Output
   On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
   On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1
   On entry X < 0.0; the function is undefined.

IFAIL= 2
   On entry Y = 0.0; the function is undefined.
   On soft failure the routine returns zero.

7. Accuracy

In principle the routine is capable of producing full machine precision. However round-off errors in internal arithmetic will result in slight loss of accuracy. This loss should never be
excessive as the algorithm does not involve any significant amplification of round-off error. It is reasonable to assume that the result is accurate to within a small multiple of the machine precision.

8. Further Comments

Users should consult the Chapter Introduction which shows the relationship of this function to the classical definitions of the elliptic integrals.

9. Example

This example program simply generates a small set of non-extreme arguments which are used with the routine to produce the table of low accuracy results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
not included in the Foundation Library.

1. Purpose

S21BBF returns a value of the symmetrised elliptic integral of the first kind, via the routine name.

2. Specification

\[
\text{DOUBLE PRECISION FUNCTION S21BBF (X, Y, Z, IFAIL)}
\]
\[
\text{INTEGER IFAIL}
\]
\[
\text{DOUBLE PRECISION X, Y, Z}
\]

3. Description

This routine calculates an approximation to the integral

\[
\frac{1}{\text{F}} \int_{0}^{\infty} \frac{\text{dt}}{2\sqrt{(t+x)(t+y)(t+z)}}
\]

where \(x, y, z \geq 0\) and at most one is zero.

The basic algorithm, which is due to Carlson [2] and [3], is to reduce the arguments recursively towards their mean by the rule:

\[
x = \min(x, y, z), z = \max(x, y, z),
\]
\[
y = \text{remaining third intermediate value argument}.
\]

(This ordering, which is possible because of the symmetry of the function, is done for technical reasons related to the avoidance of overflow and underflow.)

\[
\mu = \frac{(x + y + z)}{3}
\]
\[
X = \frac{(1-x)}{\mu}
\]
\[
Y = \frac{(1-y)}{\mu}
\]
\[
Z = \frac{(1-z)}{\mu}
\]
(lambda) = \( /x \ y + /y \ z + /z \ x \)
\( n \ \sqrt{n} \ n \ n / \ n \ n / \ n \ n \)

\[ x = (x + (\text{lambda})) / 4 \]
\( n+1 \ n \ n \ n \ n \)

\[ y = (y + (\text{lambda})) / 4 \]
\( n+1 \ n \ n \ n \ n \)

\[ z = (z + (\text{lambda})) / 4 \]
\( n+1 \ n \ n \ n \ n \)

(epsilon) = max(|X|, |Y|, |Z|) and the function may be approximated adequately by a 5th order power series:

\[
\frac{R(x,y,z)}{f(\mu)} = \frac{1}{(1 - \cdots - \cdots - \cdots)}
\]
\( \sqrt{n} \ n \)

where \( E = X \ Y + Y \ Z + Z \ X \), \( E = X \ Y \ Z \).

\[ (2 \ E \ E \ 3E \ E \ E) \]

\[ 1 \ (2 \ 2 \ 2 \ 3 \ 3) \]

The truncation error involved in using this approximation is bounded by \( (\text{epsilon}) / 4 (1 - (\text{epsilon}) ) \) and the recursive process is stopped when this truncation error is negligible compared with the machine precision.

Within the domain of definition, the function value is itself representable for all representable values of its arguments. However, for values of the arguments near the extremes the above algorithm must be modified so as to avoid causing underflows or overflows in intermediate steps. In extreme regions arguments are pre-scaled away from the extremes and compensating scaling of the result is done before returning to the calling program.

4. References

Duplication. (Preprint) Department of Physics, Iowa State University.

5. Parameters

1: X -- DOUBLE PRECISION Input

2: Y -- DOUBLE PRECISION Input

3: Z -- DOUBLE PRECISION Input
   On entry: the arguments x, y and z of the function.
   Constraint: X, Y, Z >= 0.0 and only one of X, Y and Z may be zero.

4: IFAIL -- INTEGER Input/Output
   On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
   On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1
   On entry one or more of X, Y and Z is negative; the function is undefined.

IFAIL= 2
   On entry two or more of X, Y and Z are zero; the function is undefined.

On soft failure, the routine returns zero.

7. Accuracy

In principle the routine is capable of producing full machine precision. However round-off errors in internal arithmetic will result in slight loss of accuracy. This loss should never be excessive as the algorithm does not involve any significant amplification of round-off error. It is reasonable to assume that the result is accurate to within a small multiple of the machine
8. Further Comments

Users should consult the Chapter Introduction which shows the relationship of this function to the classical definitions of the elliptic integrals.

If two arguments are equal, the function reduces to the elementary integral $R$, computed by S21BAF.

9. Example

This example program simply generates a small set of non-extreme arguments which are used with the routine to produce the table of low accuracy results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

Value of the symmetrised elliptic integral of second kind

— nags.ht —

Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is
not included in the Foundation Library.

1. Purpose

S21BCF returns a value of the symmetrised elliptic integral of the second kind, via the routine name.

2. Specification

```plaintext
DOUBLE PRECISION FUNCTION S21BCF (X, Y, Z, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X, Y, Z
```

3. Description

This routine calculates an approximate value for the integral

\[
\int_{\infty}^{3} \frac{dt}{(t+x)(t+y)(t+z)}
\]

where \( x, y \geq 0 \), at most one of \( x \) and \( y \) is zero, and \( z > 0 \).

The basic algorithm, which is due to Carlson [2] and [3], is to reduce the arguments recursively towards their mean by the rule:

\[
\begin{align*}
    x &= x \\
    0 \\
    y &= y \\
    0 \\
    z &= z \\
    0 \\
    (\mu) &= (x + y + 3z) / 5 \\
    X &= (1 - x) / (\mu) \\
    Y &= (1 - y) / (\mu) \\
    Z &= (1 - z) / (\mu)
\end{align*}
\]
CHAPTER 22. NAG LIBRARY ROUTINES

\[(\lambda) = \frac{x + y + y + z + z + x}{4}\]

\[x = \frac{(x + (\lambda))}{4}\]

\[y = \frac{(y + (\lambda))}{4}\]

\[z = \frac{(z + (\lambda))}{4}\]

For \(n\) sufficiently large,

\[(1)n\]

\[(\epsilon) = \max(|X|, |Y|, |Z|)^{-n}\]

and the function may be approximated adequately by a 5th order power series

\[R(x,y,z) = 3 \left( \sum_{m=0}^{n} \frac{(z + (\lambda))}{z} \right)\]

\[\frac{1}{(\mu)}\]

where

\[(m) (m m m)\]

\[S = \frac{(X + Y + 3Z)}{2m}\]

The truncation error in this expansion is bounded by

\[6\]

\[3(\epsilon)^n\]

and the recursive process is terminated when
The routine may fail either because it has been called with arguments outside the domain of definition, or with arguments so extreme that there is an unavoidable danger of setting underflow or overflow.

\[-3/2\]

Note: \( R(x,x,x) = x \), so there exists a region of extreme arguments for which the function value is not representable.

22.6. NAGS.HT

Value of the symmetrised elliptic integral of third kind

--- nags.ht ---

\begin{page}{manpageXXs21bdf}{NAG Documentation: s21bdf}
\beginscroll
\begin{verbatim}
S21BDF(3NAG) Foundation Library (12/10/92) S21BDF(3NAG)

S21 -- Approximations of Special Functions
S21BDF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

S21BDF returns a value of the symmetrised elliptic integral of the third kind, via the routine name.

2. Specification

DOUBLE PRECISION FUNCTION S21BDF (X, Y, Z, R, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X, Y, Z, R

3. Description

This routine calculates an approximation to the integral

\[
\int_{0}^{\infty} \frac{3}{2} \frac{dt}{(t+(\rho))(t+x)(t+y)(t+z)}
\]

where \( x, y, z \geq 0 \), \( \rho \neq 0 \) and at most one of \( x, y \) and \( z \) is zero.

If \( p < 0 \), the result computed is the Cauchy principal value of the
integral.

The basic algorithm, which is due to Carlson [2] and [3], is to reduce the arguments recursively towards their mean by the rule:

\[
\begin{align*}
x &= x_0 \\
y &= y_0 \\
z &= z_0 \\
(\rho) &= (\rho)_0 \\
\mu &= (x + y + z + 2(\rho))/5 \\
X &= (1-x)/\mu \\
Y &= (1-y)/\mu \\
Z &= (1-z)/\mu \\
P &= (1-(\rho))/\mu \\
\lambda &= \frac{\sqrt{x^2 + y^2 + z^2}}{x + y + z} \\
x &= (x + \lambda)/4 \\
y &= (y + \lambda)/4 \\
z &= (z + \lambda)/4 \\
(\rho) &= (\rho + \lambda)/4 \\
\end{align*}
\]

\[
\begin{align*}
\mu &= (x + y + z + 2(\rho))/5 \\
X &= (1-x)/\mu \\
Y &= (1-y)/\mu \\
Z &= (1-z)/\mu \\
P &= (1-(\rho))/\mu \\
\end{align*}
\]
(alpha) =\( [(\rho) \{ x + y + z \} + xyz] \)
\[
\begin{array}{c}
\alpha \\
n \\
n \\
n \\
n \\
n \\
n n n n n n n n
\end{array}
\]

2

(beta) = (\rho) ((\rho) + (\lambda))
\[
\begin{array}{c}
\beta \\
n \\
n n n n n n n
\end{array}
\]

For \( n \) sufficiently large,
\[
(\epsilon) = \max(|X|, |Y|, |Z|, |P|)^{-1} --
\begin{array}{c}
\epsilon \\
n \\
n n n n n n n
\end{array}
\]

and the function may be approximated by a 5th order power series
\[
R(x, y, z, (\rho)) = 3 > 4 R((\alpha), (\beta))
\begin{array}{c}
J \\
n \-- \\
m m m m m m m
\end{array}
\]

\[\begin{array}{c}
\begin{array}{l}
4 \quad [ \quad 3 \ 2 \quad 1 \ (3) \ 3 \ 2 \quad 3 \ (4) \ 3 \ 2 \ (3) \ 3 \ (5)] \\
\quad + \ \ \ \ \ \ [1+ -S + S + -(S) + -S + -S + S + -S] \\
\quad \quad [ \quad 7 n \ 3 n \ 22 n \ 11 n \ 13 n \ n \ 13 n ] \\
\quad / \quad 3 \\
\quad / (\mu) \\
\quad \ \ \ \ \ \ \ \ n \\
\end{array}
\end{array}\]

\[
\begin{array}{c}
\begin{array}{l}
(m) \\
m n n m n n m m
\end{array}
\end{array}
\]

where \( S = (X + Y + Z + 2P)/2m. \)
\[
\begin{array}{c}
n \\
n n n n n n n
\end{array}
\]

The truncation error in this expansion is bounded by
\[
6 / 3
3(\epsilon)/ (1-(\epsilon)) \quad \text{and the recursion process is terminated when this quantity is negligible compared with the machine precision. The routine may fail either because it has been called with arguments outside the domain of definition or with arguments so extreme that there is an unavoidable danger of setting underflow or overflow.}
\begin{array}{c}
3 \\
- - \\
2
\end{array}\]
Note: \( R(x,x,x,x) = x \), so there exists a region of extreme arguments for which the function value is not representable.

4. References

5. Parameters

1: X -- DOUBLE PRECISION Input
2: Y -- DOUBLE PRECISION Input
3: Z -- DOUBLE PRECISION Input
4: R -- DOUBLE PRECISION Input
   On entry: the arguments \( x, y, z \) and \((\rho)\) of the function.
   Constraint: \( X, Y, Z \geq 0.0, R \neq 0.0 \) and at most one of \( X, Y \) and \( Z \) may be zero.
5: IFAIL -- INTEGER Input/Output
   On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
   On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL = 1
   On entry at least one of \( X, Y \) and \( Z \) is negative, or at least two of them are zero; the function is undefined.

IFAIL = 2
   On entry \( R = 0.0 \); the function is undefined.
IFAIL = 3
On entry either R is too close to zero, or any two of X, Y
and Z are too close to zero; there is a danger of setting
overflow.

IFAIL = 4
On entry at least one of X, Y, Z and R is too large; there
is a danger of setting underflow.

IFAIL = 5
An error has occurred in a call to S21BAF. Any such
occurrence should be reported to NAG.

On soft failure, the routine returns zero.

7. Accuracy

In principle the routine is capable of producing full machine
precision. However round-off errors in internal arithmetic will
result in slight loss of accuracy. This loss should never be
excessive as the algorithm does not involve any significant
amplification of round-off error. It is reasonable to assume that
the result is accurate to within a small multiple of the machine
precision.

8. Further Comments

Users should consult the Chapter Introduction which shows the
relationship of this function to the classical definitions of the
elliptic integrals.

If the argument R is equal to any of the other arguments, the
function reduces to the integral $R$, computed by S21BCF.

9. Example

This example program simply generates a small set of non-extreme
arguments which are used with the routine to produce the table of
low accuracy results.

The example program is not reproduced here. The source code for
each example programs is distributed with the NAG Foundation
Library software and should be available on-line.
Mathematical Constants

1. Scope of the Chapter

This chapter is concerned with the provision of mathematical constants required by other routines within the Library.

It should be noted that because of the trivial nature of the routines individual routine documents are not provided.

2. Background to the Problems

Some Library routines require mathematical constants to maximum machine precision. These routines call Chapter X01 and thus lessen the number of changes that have to be made between different implementations of the Library.

3. Recommendations on Choice and Use of Routines

Although these routines are primarily intended for use by other routines they may be accessed directly by the user:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Fortran Specification</th>
</tr>
</thead>
<tbody>
<tr>
<td>(pi)</td>
<td>DOUBLE PRECISION FUNCTION X01AAF(X)</td>
</tr>
<tr>
<td></td>
<td>DOUBLE PRECISION X</td>
</tr>
</tbody>
</table>
(gamma)  DOUBLE PRECISION FUNCTION X01ABF(X)
(Euler constant)  DOUBLE PRECISION X

The argument X of these routines is a dummy argument.

Machine Constants

— nafx.ht —
of a single implementation they are constants.

The parameters are intended for use primarily by other routines in the Library, but users of the Library may sometimes need to refer to them directly.

Each parameter-value is returned by a separate Fortran function. Because of the trivial nature of the functions, individual routine documents are not provided; the necessary details are given in Section 3 of this Introduction.

2. Background to the Problems

2.1. Floating-Point Arithmetic

2.1.1. A model of floating-point arithmetic

In order to characterise the important properties of floating-point arithmetic by means of a small number of parameters, NAG uses a simplified model of floating-point arithmetic. The parameters of the model can be chosen to provide a sufficiently close description of the behaviour of actual implementations of floating-point arithmetic, but not, in general, an exact description; actual implementations vary too much in the details of how numbers are represented or arithmetic operations are performed.

The model is based on that developed by Brown [1], but differs in some respects. The essential features are summarised here.

The model is characterised by four integer parameters and one logical parameter. The four integer parameters are:

- \( b \) : the base
- \( p \) : the precision (i.e. the number of significant base-B digits)
- \( e_{\min} \) : the minimum exponent
- \( e_{\max} \) : the maximum exponent

These parameters define a set of numerical values of the form:

\[ e \frac{f}{b} \]

where the exponent \( e \) must lie in the range \([e_{\min}, e_{\max}]\), and the
fraction $f$ (also called the mantissa or significand) lies in the range $[1/b, 1)$, and may be written:

$$f = 0.f_1 f_2 \ldots f_p$$

Thus $f$ is a $p$-digit fraction to the base $b$; the $f_i$ are the base-$b$ digits of the fraction: they are integers in the range 0 to $b-1$, and the leading digit $f_1$ must not be zero.

The set of values so defined (together with zero) are called model numbers. For example, if $b=10$, $p=5$, $e_{\min} = -99$ and $e_{\max} = +99$, then a typical model number is $0.12345 \times 10^{67}$.

The model numbers must obey certain rules for the computed results of the following basic arithmetic operations: addition, subtraction, multiplication, negation, absolute value, and comparisons. The rules depend on the value of the logical parameter $\text{ROUNDS}$.

If $\text{ROUNDS}$ is true, then the computed result must be the nearest model number to the exact result (assuming that overflow or underflow does not occur); if the exact result is midway between two model numbers, then it may be rounded either way.

If $\text{ROUNDS}$ is false, then: if the exact result is a model number, the computed result must be equal to the exact result; otherwise, the computed result may be either of the adjacent model numbers on either side of the exact result.

For division and square root, this latter rule is further relaxed (regardless of the value of $\text{ROUNDS}$): the computed result may also be one of the next adjacent model numbers on either side of the permitted values just stated.

On some machines, the full set of representable floating-point numbers conforms to the rules of the model with appropriate values of $b$, $p$, $e_{\min}$, $e_{\max}$ and $\text{ROUNDS}$. For example, for machines with IEEE arithmetic, in double precision:

$$b = 2$$

$$p = 53$$
For other machines, values of the model parameters must be chosen which define a large subset of the representable numbers; typically it may be necessary to decrease \( p \) by 1 (in which case \texttt{ROUNDS} is always set to false), or to increase \( e \) or decrease \( \min e \) by a little bit. There are additional rules to ensure that arithmetic operations on those representable numbers which are not model numbers, are consistent with arithmetic on model numbers.

(Note: the model used here differs from that described in Brown [1] in the following respects: square-root is treated, like division, as a weakly supported operator; and the logical parameter \texttt{ROUNDS} has been introduced to take account of machines with good rounding.)

2.1.2. Derived parameters of floating-point arithmetic

Most numerical algorithms require access, not to the basic parameters of the model, but to certain derived values, of which the most important are:

(1) \( 1-p \)

the machine precision = \((-)*b \) if \texttt{ROUNDS} is true,

(\textit{epsilon})

(2)

\( 1-p \)

= \( b \) otherwise (but see Note below).

\( e \rightarrow -1 \)

\( \min e \)

the smallest positive = \( b \)

model number:

\( e \rightarrow \)

\( -p \)

\( \max e \)

the largest positive = \((1-b)*b \)

model number:

Note: this value is increased very slightly in some implementations to ensure that the computed result of \( 1+(\text{epsilon}) \) or \( 1-(\text{epsilon}) \) differs from 1. For example in IEEE binary single -24 -47
Two additional derived values are used in the NAG Foundation Library. Their definitions depend not only on the properties of the basic arithmetic operations just considered, but also on properties of some of the elementary functions. We define the safe range parameter to be the smallest positive model number $z$ such that for any $x$ in the range $[z,1/z]$ the following can be computed without undue loss of accuracy, overflow, underflow or other error:

- $-x$
- $1/x$
- $-1/x$
- $\text{SQRT}(x)$
- $\text{LOG}(x)$
- $\text{EXP}(\text{LOG}(x))$
- $y^{\text{LOG}(x)/\text{LOG}(y)}$ for any $y$

In a similar fashion we define the safe range parameter for complex arithmetic as the smallest positive model number $z$ such that for any $x$ in the range $[z,1/z]$ the following can be computed without any undue loss of accuracy, overflow, underflow or other error:

- $-w$
- $1/w$
- $-1/w$
- $\text{SQRT}(w)$
- $\text{LOG}(w)$
- $\text{EXP}(\text{LOG}(w))$
- $y^{\text{LOG}(w)/\text{LOG}(y)}$ for any $y$
- $\text{ABS}(w)$

where $w$ is any of $x$, $ix$, $x+ix$, $1/x$, $i/x$, $1/x+i/x$, and $i$ is the square root of $-1$. 
This parameter was introduced to take account of the quality of complex arithmetic on the machine. On machines with well implemented complex arithmetic, its value will differ from that of the real safe range parameter by a small multiplying factor less than 10. For poorly implemented complex arithmetic this factor may be larger by many orders of magnitude.

2.2. Other Aspects of the Computing Environment

No attempt has been made to characterise comprehensively any other aspects of the computing environment. The other functions in this chapter provide specific information that is occasionally required by routines in the Library.

2.3. References

3. Recommendations on Choice and Use of Routines

3.1. Parameters of Floating-point Arithmetic

DOUBLE PRECISION FUNCTION returns the machine precision i.e.
\( X02AJF() \)
\[ (1-p) 1-p \]
\[ (-)^b \quad \text{if ROUNDS is true or } b \]
\[ (2) \]
\[ \text{otherwise (or a value very slightly larger than this, see Section 2.1.2) } \]

DOUBLE PRECISION FUNCTION returns the smallest positive model
\( X02ARF() \)
\[ e^{-1} \min \]
number i.e. \( b \)

DOUBLE PRECISION FUNCTION returns the largest positive model
\( X02ALF() \)
\[ e^{-p} \max \]
number i.e. \( (1-b) \) \( *b \)

DOUBLE PRECISION FUNCTION returns the safe range parameter as defined in Section 2.1.2
\( X02AMF() \)

DOUBLE PRECISION FUNCTION returns the safe range parameter for complex arithmetic as defined in Section 2.1.2
\( X02ANF() \)

INTEGER FUNCTION \( X02BHF() \) returns the model parameter \( b \)
INTEGER FUNCTION X02BJF() returns the model parameter \( p \)
INTEGER FUNCTION X02BKF() returns the model parameter \( e_{\text{min}} \)
INTEGER FUNCTION X02BLF() returns the model parameter \( e_{\text{max}} \)
LOGICAL FUNCTION X02DJF() returns the model parameter ROUNDS

3.2. Parameters of Other Aspects of the Computing Environment

DOUBLE PRECISION FUNCTION X02AHF(X) returns the largest positive real argument for which the SIN and COS routines return a result with some meaningful accuracy

INTEGER FUNCTION X02BBF(X) returns the largest positive integer value

INTEGER FUNCTION X02BEF(X) returns the maximum number of decimal digits which can be accurately represented over the whole range of floating-point numbers

The argument \( X \) of these routines is a dummy argument.

4. Example Program Text

The example program simply prints the values of all the functions in Chapter X02. Obviously the results will vary from one implementation of the Library to another.
CHAPTER 22. NAG LIBRARY ROUTINES

X02ANF Safe range of complex floating-point arithmetic
X02BBF Largest representable integer
X02BEF Maximum number of decimal digits that can be represented
X02BHF Parameter of floating-point arithmetic model, b
X02BJF Parameter of floating-point arithmetic model, p
X02BKF Parameter of floating-point arithmetic model, e_{min}
X02BLF Parameter of floating-point arithmetic model, e_{max}
X02DJF Parameter of floating-point arithmetic model, ROUNDS

---

Input/Output Utilities

--- nagx.ht ---

---

X04(3NAG) Foundation Library (12/10/92) X04(3NAG)

X04 -- Input/Output Utilities Introduction -- X04
Chapter X04
Input/Output Utilities

1. Scope of the Chapter

This chapter contains utility routines concerned with input and output to or from an external file.
2. Background to the Problems

2.1. Output from NAG Foundation Library Routines

Output from NAG Foundation Library routines to an external file falls into two categories:

(a) Error messages which are always associated with an error exit from a routine, that is, with a non-zero value of IFAIL as specified in Section 6 of the routine document.

(b) Advisory messages which include output of final results, output of intermediate results to monitor the course of a computation, and various warning or informative messages.

Each category of output is written to its own Fortran output unit - the error message unit or the advisory message unit. In practice these may be the same unit number. Default unit numbers are provided for each implementation of the Library (see the Users' Note); they may be changed by users. Output of error messages may be controlled by the setting of IFAIL (see the Essential Introduction). Output of advisory messages may usually be controlled by the setting of some other parameter (e.g. MSGVLVL) (or in some routines also by IFAIL). An alternative mechanism for completely suppressing output is to set the relevant unit number < 0.

For further information about error and advisory messages, see Chapter P01.

2.2. Matrix Printing Routines

Routines are provided to allow formatted output of general rectangular or triangular matrices stored in a two-dimensional array (real and complex data types).

All output is directed to the unit number for output of advisory messages, which may be altered by a call to X04ABF.

3. Recommendations on Choice and Use of Routines

Apart from the obvious utility of the matrix printing routines, users of the Library may need to call routines in Chapter X04 for the following purposes:

- if the default unit number for error messages (given in the Users' Note for your implementation) is not satisfactory, it may be changed to a new value NERR by the statement

  CALL X04AAF(1,NERR)
Similarly the unit number for advisory messages may be changed to a new value NADV by the statement

\[
\text{CALL X04ABF(1,NADV)}
\]

4. Index

Accessing unit number:
- of advisory message unit \( \text{X04ABF} \)
- of error message unit \( \text{X04AAF} \)

Printing matrices:
- general complex matrix \( \text{X04DAF} \)
- general real matrix \( \text{X04CAF} \)

---

Value of the current error message unit number

---

\[
\text{X04AAF(3NAG) Foundation Library (12/10/92) X04AAF(3NAG)}
\]
Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

X04AAF returns the value of the current error message unit number, or sets the current error message unit number to a new value.

2. Specification

```fortran
SUBROUTINE X04AAF (IFLAG, NERR)
INTEGER IFLAG, NERR
```

3. Description

This routine enables those library routines which output error messages, to determine the number of the output unit to which the error messages are to be sent; in this case X04AAF is called with IFLAG = 0. X04AAF may also be called with IFLAG = 1 to set the unit number to a specified value. Otherwise a default value (stated in the Users’ Note for your implementation) is returned.

Records written to this output unit by other library routines are at most 80 characters long (including a line-printer carriage control character).

Note that if the unit number is set < 0, no messages will be output.

4. References

None.

5. Parameters

1: IFLAG -- INTEGER  
   Input
   On entry: the action to be taken (see NERR). Constraint: IFLAG = 0 or 1.

2: NERR -- INTEGER  
   Input/Output
   On entry:
if IFLAG = 0, NERR need not be set;

if IFLAG = 1, NERR must specify the new error message unit number.

On exit:
  if IFLAG = 0, NERR is set to the current error message unit number,

    if IFLAG = 1, NERR is unchanged.

Note that Fortran unit numbers must be positive or zero. If NERR is set < 0, output of error messages is totally suppressed.

6. Error Indicators and Warnings

None.

7. Accuracy

Not applicable.

8. Further Comments

The time taken by the routine is negligible.

9. Example

In this example X04AAF is called by the user's main program to make the error message from the routine DUMMY appear on the same unit as the rest of the output (unit 6). Normally a NAG Foundation Library routine with an IFAIL parameter (see Essential Introduction) would take the place of DUMMY.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
X04ABF returns the value of the current advisory message unit number, or sets the current advisory message unit number to a new value.

2. Specification

SUBROUTINE X04ABF (IFLAG, NADV)
INTEGER IFLAG, NADV

3. Description

This routine enables those library routines which output advisory messages, to determine the number of the output unit to which the advisory messages are to be sent; in this case X04ABF is called with IFLAG = 0. X04ABF may also be called with IFLAG = 1 to set the unit number to a specified value. Otherwise a default value (stated in the User's Note for your implementation) is returned.

Records written to this output unit by other library routines are at most 120 characters long (including a line-printer carriage control character), unless those library routines allow users to specify longer records.

Note that if the unit number is set < 0, no messages will be output.

4. References

None.

5. Parameters
CHAPTER 22. NAG LIBRARY ROUTINES

1: IFLAG -- INTEGER
   Input
   On entry: the action to be taken (see NADV). Constraint:
   IFLAG = 0 or 1.

2: NADV -- INTEGER
   Input/Output
   On entry:
   if IFLAG = 0, NADV need not be set;
   if IFLAG = 1, NADV must specify the new advisory
   message unit number.
   On exit:
   if IFLAG = 0, NADV is set to the current advisory
   message unit number;
   if IFLAG = 1, NADV is unchanged.
   Note that Fortran unit numbers must be positive or zero. If
   NADV is set < 0, output of advisory messages is totally
   suppressed.

6. Error Indicators and Warnings

None.

7. Accuracy

Not applicable.

8. Further Comments

The time taken by this routine is negligible.

9. Example

In this example X04ABF is called by the user’s main program to
make the advisory message from the routine DUMMY appear on the
same unit as the rest of the output (unit 6). Normally a NAG
Foundation Library routine with an IFAIL parameter (see Essential
Introduction) would take the place of DUMMY.

The example program is not reproduced here. The source code for
all example programs is distributed with the NAG Foundation
Library software and should be available on-line.
Print a real matrix stored in a two-dimensional array

--- nagx.ht ---

\begin{verbatim}
SUBROUTINE X04CAF (MATRIX, DIAG, M, N, A, LDA, TITLE, IFAIL)
    INTEGER M, N, LDA, IFAIL
    DOUBLE PRECISION A(LDA,*)
    CHARACTER*1 MATRIX, DIAG
    CHARACTER*(*) TITLE

3. Description

X04CAF prints a real matrix. It is an easy-to-use driver for X04CBF(*). The routine uses default values for the format in which numbers are printed, for labelling the rows and columns, and for output record length.

X04CAF will choose a format code such that numbers will be printed with either an F8.4, F11.4 or a 1PE13.4 format. The F8.4 code is chosen if the sizes of all the matrix elements to be printed lie between 0.001 and 1.0. The F11.4 code is chosen if the sizes of all the matrix elements to be printed lie between 0.001 and 9999.9999. Otherwise the 1PE13.4 code is chosen.
\end{verbatim}
The matrix is printed with integer row and column labels, and with a maximum record length of 80.

The matrix is output to the unit defined by X04ABF.

4. References

None.

5. Parameters

1: MATRIX -- CHARACTER*1 Input
   On entry: indicates the part of the matrix to be printed, as follows:

   MATRIX = 'G' (General), the whole of the rectangular matrix.

   MATRIX = 'L' (Lower), the lower triangle of the matrix, or the lower trapezium if the matrix has more rows than columns.

   MATRIX = 'U' (Upper), the upper triangle of the matrix, or the upper trapezium if the matrix has more columns than rows. Constraint: MATRIX must be one of 'G', 'L' or 'U'.

2: DIAG -- CHARACTER*1 Input
   On entry: unless MATRIX = 'G', DIAG must specify whether the diagonal elements of the matrix are to be printed, as follows:

   DIAG = 'B' (Blank), the diagonal elements of the matrix are not referenced and not printed.

   DIAG = 'U' (Unit diagonal), the diagonal elements of the matrix are not referenced, but are assumed all to be unity, and are printed as such.

   DIAG = 'N' (Non-unit diagonal), the diagonal elements of the matrix are referenced and printed.

   If MATRIX = 'G', then DIAG need not be set. Constraint: If MATRIX /= 'G', then DIAG must be one of 'B', 'U' or 'N'.

3: M -- INTEGER Input

4: N -- INTEGER Input
   On entry: the number of rows and columns of the matrix, respectively, to be printed.
If either of \( M \) or \( N \) is less than 1, X04CAF will exit immediately after printing TITLE; no row or column labels are printed.

5: \( A(LDA,*) \) -- DOUBLE PRECISION array
   Input
   Note: the second dimension of the array \( A \) must be at least \( \max(1,N) \).
   On entry: the matrix to be printed. Only the elements that will be referred to, as specified by parameters \( \text{MATRIX} \) and \( \text{DIAG} \), need be set.

6: \( LDA \) -- INTEGER
   Input
   On entry:
   the first dimension of the array \( A \) as declared in the (sub)program from which X04CAF is called.
   Constraint: \( LDA \geq M \).

7: \( TITLE \) -- CHARACTER\((\ast)\) Input
   On entry: a title to be printed above the matrix. If \( TITLE = ' ' \), no title (and no blank line) will be printed.
   If \( TITLE \) contains more than 80 characters, the contents of \( TITLE \) will be wrapped onto more than one line, with the break after 80 characters.
   Any trailing blank characters in \( TITLE \) are ignored.

8: \( IFAIL \) -- INTEGER
   Input/Output
   On entry: \( IFAIL \) must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
   On exit: \( IFAIL = 0 \) unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry \( IFAIL = 0 \) or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

\( IFAIL=1 \)
   On entry \( \text{MATRIX} /= 'G', 'L' \) or \( 'U' \).

\( IFAIL=2 \)
   On entry \( \text{MATRIX} = 'L' \) or \( 'U' \), but \( \text{DIAG} /= 'N', 'U' \) or \( 'B' \).

\( IFAIL=3 \)
   On entry \( LDA < M \).
7. Accuracy

Not applicable.

8. Further Comments

A call to X04CAF is equivalent to a call to X04CBF(*) with the following argument values:

NCOLS = 80
INDENT = 0
LABROW = 'I'
LABCOL = 'I'
FORMAT = ' ' 

9. Example

This example program calls X04CAF twice, first to print a 3 by 5 rectangular matrix, and then to print a 5 by 5 lower triangular matrix.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

X04DAF is an easy-to-use routine to print a complex matrix stored in a two-dimensional array.

2. Specification

```
SUBROUTINE X04DAF (MATRIX, DIAG, M, N, A, LDA, TITLE, IFAIL)
  INTEGER M, N, LDA, IFAIL
  COMPLEX(KIND(1.0D0)) A(LDA,*)
  CHARACTER*1 MATRIX, DIAG
  CHARACTER*(*) TITLE
```

3. Description

X04DAF prints a complex matrix. It is an easy-to-use driver for X04DBF(*). The routine uses default values for the format in which numbers are printed, for labelling the rows and columns, and for output record length.

X04DAF will choose a format code such that numbers will be printed with either an F8.4, F11.4 or a 1PE13.4 format. The F8.4 code is chosen if the sizes of all the matrix elements to be printed lie between 0.001 and 1.0. The F11.4 code is chosen if the sizes of all the matrix elements to be printed lie between 0.001 and 9999.9999. Otherwise the 1PE13.4 code is chosen. The chosen code is used to print each complex element of the matrix with the real part above the imaginary part.

The matrix is printed with integer row and column labels, and with a maximum record length of 80.

The matrix is output to the unit defined by X04ABF.

4. References

None.

5. Parameters
1: MATRIX -- CHARACTER*1 Input
   On entry: indicates the part of the matrix to be printed, as follows:

   MATRIX = 'G' (General), the whole of the rectangular matrix.

   MATRIX = 'L' (Lower), the lower triangle of the matrix, or
   the lower trapezium if the matrix has more rows than
   columns.

   MATRIX = 'U' (Upper), the upper triangle of the matrix, or
   the upper trapezium if the matrix has more columns than
   rows. Constraint: MATRIX must be one of 'G', 'L' or 'U'.

2: DIAG -- CHARACTER*1 Input
   On entry: unless MATRIX = 'G', DIAG must specify whether the
diagonal elements of the matrix are to be printed, as follows:

   DIAG = 'B' (Blank), the diagonal elements of the matrix are
   not referenced and not printed.

   DIAG = 'U' (Unit diagonal), the diagonal elements of the
   matrix are not referenced, but are assumed all to be unity,
   and are printed as such.

   DIAG = 'N' (Non-unit diagonal), the diagonal elements of the
   matrix are referenced and printed.

   If MATRIX = 'G', then DIAG need not be set. Constraint: If
   MATRIX /= 'G', then DIAG must be one of 'B', 'U' or 'N'.

3: M -- INTEGER Input

4: N -- INTEGER Input
   On entry: the number of rows and columns of the matrix,
   respectively, to be printed.

   If either of M or N is less than 1, X04DAF will exit
   immediately after printing TITLE; no row or column labels
   are printed.

5: A(LDA,*) -- COMPLEX(KIND(1.0D)) array Input
   Note: the second dimension of the array A must be at least
   max(1,N).

   On entry: the matrix to be printed. Only the elements that
   will be referred to, as specified by parameters MATRIX and
   DIAG, need be set.

6: LDA -- INTEGER Input
On entry: the first dimension of the array A as declared in the (sub)program from which X04DAF is called.
Constraint: LDA >= M.

7: TITLE -- CHARACTER(*)

On entry: a title to be printed above the matrix. If TITLE = ' ', no title (and no blank line) will be printed.
If TITLE contains more than 80 characters, the contents of TITLE will be wrapped onto more than one line, with the break after 80 characters.
Any trailing blank characters in TITLE are ignored.

8: IFAIL -- INTEGER

On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:
If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1
On entry MATRIX /= 'G', 'L' or 'U'.

IFAIL= 2
On entry MATRIX = 'L' or 'U', but DIAG /= 'N', 'U' or 'B'.

IFAIL= 3
On entry LDA < M.

7. Accuracy

Not applicable.

8. Further Comments

A call to X04DAF is equivalent to a call to X04DBF(*) with the following argument values:
NCOLS = 80
INDENT = 0
LABROW = 'I'
LABCOL = 'I'
FORMAT = ', '
USEFRM = 'A'

9. Example

This example program calls X04DAF twice, first to print a 4 by 3 rectangular matrix, and then to print a 4 by 4 lower triangular matrix.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

---

Date and Time Utilities

--- nagx.ht ---

---

X05(3NAG) Foundation Library (12/10/92) X05(3NAG)

X05 -- Date and Time Utilities

Chapter X05
Date and Time Utilities

1. Scope of the Chapter

This chapter provides routines to obtain the current real time, and the amount of processor time used.
2. Background to the Problems

2.1. Real Time

Routines are provided to obtain the current time in two different formats, and to compare two such times.

2.2. Processor Time

A routine is provided to return the current amount of processor time used. This allows the timing of a particular routine or section of code.

3. Recommendations on Choice and Use of Routines

X05AAF returns the current date/time in integer format.

X05ABF converts from integer to character string date/time.

X05ACF compares two date/time character strings.

X05BAF returns the amount of processor time used.

X05 -- Date and Time Utilities

Chapter X05

Date and Time Utilities

X05AAF Return date and time as an array of integers

X05ABF Convert array of integers representing date and time to character string

X05ACF Compare two character strings representing date and time

X05BAF Return the CPU time

\end{verbatim}
\endscroll
\end{page}
Returns the current date and time

— nagx.ht —

\begin{verbatim}
X05AAF(3NAG) Foundation Library (12/10/92) X05AAF(3NAG)

X05 -- Date and Time Utilities
X05AAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

X05AAF returns the current date and time.

2. Specification

SUBROUTINE X05AAF (ITIME)
INTEGER ITIME(7)

3. Description

X05AAF returns the current date and time as a set of seven integers.

4. References

None.

5. Parameters

1: ITIME(7) -- INTEGER array Output
On exit: the current date and time, as follows:

ITIME(1) contains the current year.

ITIME(2) contains the current month, in the range 1--12.
ITIME(3) contains the current day, in the range 1--31.

ITIME(4) contains the current hour, in the range 0--23.

ITIME(5) contains the current minute, in the range 0--59.

ITIME(6) contains the current second, in the range 0--59.

ITIME(7) contains the current millisecond, in the range 0--999.

6. Error Indicators and Warnings

None.

7. Accuracy

The accuracy of this routine depends on the accuracy of the host machine. In particular, on some machines it may not be possible to return a value for the current millisecond, for example. In this case, the value returned will be zero.

8. Further Comments

None.

9. Example

This program prints out the vector ITIME after a call to X05AAF.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

---

From seven-integer format time and date to character string
1. Purpose

X05ABF converts from a seven-integer format time and date, as returned by X05AAF, into a character string, returned via the routine name.

2. Specification

```
CHARACTER*30 FUNCTION X05ABF (ITIME)
INTEGER ITIME(7)
```

3. Description

X05ABF returns a character string of length 30 which contains the date and time as supplied in argument ITIME. On exit, the character string has the following format:

```
'DAY XXTH MTH YEAR HR:MN:SC.MIL,'
```

where

- **DAY** is one of 'Sun', 'Mon', 'Tue', 'Wed', 'Thu', 'Fri', 'Sat',
- **XX** is an integer denoting the day of the month,
- **TH** is one of 'st', 'nd', 'rd', 'th',
- **MTH** is one of 'Jan', 'Feb', 'Mar', 'Apr', 'May', 'Jun', 'Jul', 'Aug', 'Sep', 'Oct', 'Nov', 'Dec',
- **YEAR** is the year as a four digit integer,
- **HR** is the hour,
- **MN** is the minute,
SC is the second,

MIL is the millisecond.

If on entry the date in ITIME is invalid, the string returned is

4. References

None.

5. Parameters

1: ITIME(7) -- INTEGER array Input
   On entry: a date and time in the format returned by X05AAF, as follows:
   ITIME must contain the year as a positive integer.
   (1)
   ITIME must contain the month, in the range 1-12.
   (2)
   ITIME must contain the day, in the range 1 to p, where
   (3) p = 28, 29, 30 or 31, depending on the month and year.
   ITIME must contain the hour, in the range 0-23.
   (4)
   ITIME must contain the minute, in the range 0-59.
   (5)
   ITIME must contain the second, in the range 0-59.
   (6)
   ITIME must contain the millisecond, in the range 0-999.

6. Error Indicators and Warnings

None.

7. Accuracy

The day name included as part of the character string returned by this routine is calculated assuming that the date is part of the Gregorian calendar. This calendar has been in operation in Europe since October the 15th 1582, and in Great Britain since September the 14th 1752. Entry to this routine with a date earlier than these will therefore not return a day name that is historically
accurate.

8. Further Comments

Two dates stored in character string format, as returned by this routine, may be compared by X05ACF.

9. Example

This program initialises a time in ITIME, and converts it to character format by a call to X05ABF.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

Compares two date/time character strings

— nagx.ht —

X05ACF(3NAG) Foundation Library (12/10/92) X05ACF(3NAG)

X05 -- Date and Time Utilities X05ACF
X05ACF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users’ Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

X05ACF compares two date/time character strings, each stored in the format returned by X05ABF.
2. Specification

    INTEGER FUNCTION X05ACF (CTIME1, CTIME2)
    CHARACTER*(*) CTIME1, CTIME2

3. Description

X05ACF compares two date/time character strings, and returns an integer that specifies which one is the earliest. The result is an integer returned through the routine name, with meaning as follows:

- X05ACF = -1: the first date/time string is earlier than the second.
- X05ACF = 0: the two date/time strings are equivalent.
- X05ACF = 1: the first date/time string is later than the second.

4. References

None.

5. Parameters

1: CTIME1 -- CHARACTER*(*) Input
2: CTIME2 -- CHARACTER*(*) Input

On entry: the date/time strings to be compared. These are expected to be in the format returned by X05ABF, although X05ACF will still attempt to interpret the strings if they vary slightly from this format. See Section 8 for further details.

6. Error Indicators and Warnings

None.

7. Accuracy

Not applicable.

8. Further Comments

For flexibility, X05ACF will accept various formats for the two date/time strings CTIME1 and CTIME2.

The strings do not have to be the same length. It is permissible,
for example, to enter with one or both of the strings truncated to a smaller length, in which case missing fields are treated as zero.

Each character string may be of any length, but everything after character 80 is ignored.

Each string may or may not include an alphabetic day name, such as 'Wednesday', at its start. These day names are ignored, and no check is made that the day name corresponds correctly to the rest of the date.

The month name may contain any number of characters provided it uniquely identifies the month, however all characters that are supplied are significant.

Each field in the character string must be separated by one or more spaces.

The case of all alphabetic characters is insignificant.

Any field in a date time string that is indecipherable according to the above rules will be converted to a zero value internally. Thus two strings that are completely indecipherable will compare equal.

According to these rules, all the following date/time strings are equivalent:

'Thursday 10th July 1958 12:43:17.320'

'THU 10th JULY 1958 12:43:17.320'

'10th Jul 1958 12:43:17.320'

9. Example

This program initialises two date/time strings, and compares them by a call to X05ACF.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.
Amount of processor time used

--- nagx.ht ---

X05BAF(3NAG) Foundation Library (12/10/92) X05BAF(3NAG)

X05 -- Date and Time Utilities X05BAF
X05BAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

X05BAF returns the amount of processor time used since an unspecified previous time, via the routine name.

2. Specification

    DOUBLE PRECISION FUNCTION X05BAF ()

3. Description

X05BAF returns the number of seconds of processor time used since some previous time. The previous time is system dependent, but may be, for example, the time the current job or the current program started running.

If the system clock of the host machine is inaccessible for any reason, X05BAF returns the value zero.

4. References

None.

5. Parameters
6. Error Indicators and Warnings

None.

7. Accuracy

The accuracy of the value returned depends on the accuracy of the system clock on the host machine.

8. Further Comments

Since the value returned by X05BAF is the amount of processor time since some unspecified earlier time, no significance should be placed on the value other than as a marker to be compared with some later figure returned by X05BAF. The amount of processor time that has elapsed between two calls of X05BAF can be simply calculated as the earlier value subtracted from the later value.

9. Example

This program makes a call to X05BAF, performs some computations, makes another call to X05BAF, and gives the time used by the computations as the difference between the two returned values.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

About the Axiom/NAG Expert System

In applied mathematics, electronic and chemical engineering, the modelling process can produce a number of mathematical problems which require numerical solutions for which symbolic methods are either not possible or not obvious. With the plethora of numerical library routines for the solution of these problems often the numerical analyst has to answer the question \textit{Which routine to choose?}

Some analysis needs to be carried out before the appropriate routine can be identified i.e. \textit{How stiff is this ODE?} and \textit{Is this function continuous?} It may well be the case that more than one routine is applicable to the problem. So the question may become \textit{Which is likely to be the best?} Such a choice may be critical for both accuracy and efficiency.

An expert system is thus required to make this choice based on the result of its own analysis of the problem, call the routine and act on the outcome. This may be to put the answer in a relevant form or react to an apparent failure of the chosen routine and thus choose and call an alternative. It should also have sufficient explanation mechanisms to inform on the choice of routine and the reasons for that choice.
Introduction to the Axiom/NAG Expert System

Deciding amongst, and then implementing, several possible approaches to solving a numerical problem can be daunting for a novice user, or tedious for an expert. Different attributes of the problem need to be identified and their possible interactions weighed up before a final decision about which method to use can be made.

The implementation is then largely an automatic, if laborious, process of writing, compiling and linking usually Fortran code. The aim is to build an expert system which will use computer algebra to analyse such features of a problem, inference mechanisms and a knowledge base to choose a numerical method appropriate to the solution of a given problem.

Any interactive system is constrained by the need to provide a reasonable response time for the user. Given the complexity of some of the analysis our system will need to do, it is clear that we should only aim to select a good method, rather than try to identify the best one available. The overall goal is to provide a "black-box" interface to numerical software which allows non-experts access to its full potential. It will also provide explanation mechanisms commensurate with its role as a teaching aid.

Given, say, an integration to perform (which may or may not be able to be handled symbolically), the system should choose and apply an appropriate method, thus mirroring as closely as possible the way that an experienced numerical analyst would think so, for example, given an integration to perform:

\begin{verbatim}
\int x \text{d}x
\end{verbatim}

the experienced analyst would see that the integral is semi-infinite and transform it by splitting the range and transforming the integral over \begin{verbatim}
[1, \text{infty}]
\end{verbatim} into an integral over \begin{verbatim}
[0, 1]
\end{verbatim} using the transformation \begin{verbatim}
x \rightarrow 1/t.
\end{verbatim} A different numerical routine might be used over each sub-region and the results added to give the final answer.
It then requires
the translation of the problem into Fortran code which may be extensive.
Even with this simple example, the process is quite involved.
\end{scroll}
\end{page}

Example using the Axiom/NAG Expert System

could be minimized as follows:
\begin{verbatim}
(X[2]-2*X[3])**4 + 10*(X[1]-X[4])**4, [3,-1,0,1], [1,-2,\%minusInfinity,1], 
[3,0,\%plusInfinity,3])\bound{ans3} }
\end{verbatim}

It creates a composite structure for which the field containing the minimum can be expanded as required.
\begin{verbatim}
\spadpaste{ans3 . objf\free{ans3}}
\end{verbatim}
Some features are either present or absent in a problem. Examples of such binary decisions include \emph{is a matrix symmetric?} and \emph{is a function continuous?} However in practice many questions are about the \emph{degree} to which a problem exhibits a property: \emph{how much does a function oscillate?}, or \emph{how stiff are these differential equations?}

We have therefore created decision agents of two types, reflecting their property --- \emph{Binary Agents} are Boolean functions returning either true or false and \emph{Intensity Functions} are quantitative and return a range of different values, either numerical or structured types. The framework we are developing is able to deal with both these forms of information.

In any given problem area (for example solving ordinary differential equations, optimization etc.) we have a selection of \emph{methods}. These might be to use a particular NAG routine, or they might involve employing a higher-level strategy such as transforming the problem...
into an equivalent, but easier to solve, form.

Associated with every method we define a measure function which assesses the suitability of that method to a particular problem. Each measure function has access to a range of symbolic agents which can answer questions about the various properties of the problem in hand.

Inference Mechanisms

The inference machine will take the problem description as provided by the user and perform an initial analysis to verify its validity. It will consider, in turn, all of the available methods within its knowledge base which might solve that problem. In doing so it analyses the input problem to find out about any attributes that could affect the ability of the methods under consideration to perform effectively.

Some of these measures may use lazy evaluation in the sense that, if a method already assessed is believed to be a good candidate, and if evaluating the current measure will be relatively expensive, then that measure will not be evaluated unless later evidence shows that the selected method is not, in fact, a successful strategy, for example if it has failed.
Method Domains

⇒ “notitle” (UXANNAMeas) 24.1 on page 3994
⇒ “notitle” (UXANNAgent) 24.1 on page 3995
⇒ “notitle” (UXANNAEx) 24.1 on page 3984

An Axiom \textit{domain} has been created for each method or strategy for solving the problem. These method domains each implement two functions with a uniform (method independant) interface.

\textbf{measure:} A function which calculates an estimate of suitability of this particular method to the problem if there is a possibility that the method under consideration is more appropriate than one already investigated.

If it may be possible to improve on the current favourite method, the function will call computational agents to analyse the problem for specific features and calculate the measure from the results these agents return, using a variation on the Lucks/Gladwell intensity and compatibility model if conflict between attributes, as investigated by these computational agents, may be present.

\textbf{implementation:} A function which may be one of two distinct kinds. The first kind uses the interface to the NAG Library to call a particular routine with the required parameters. Some of the parameters may need to be calculated from the data provided before the external function call.

The other kind will apply a ‘‘high level’’ strategy to try to solve the problem e.g. a transformation of an expression from one that is difficult to solve to one which is easier, or a splitting of the problem into several more easily solvable parts. For example, for a solution of the equation above, since the integral is semi-infinite we might wish to transform the range by, say, using the mapping \( \iota y \rightarrow 1/x \) on the section \( \iota 1 < x < \infty \) and adding the result to the unmapped section \( \iota 0 < x < 1 \).
Measure Functions

⇒ “notitle” (UXANNAgent) 24.1 on page 3995
⇒ “notitle” (UXANNAEx) 24.1 on page 3984

Each measure function will estimate the ability of a particular method to solve a problem. It will consult whichever agents are needed to perform analysis on the problem in order to calculate the measure. There is a parameter which would contain the best compatibility value found so far.

However, the interpretation we give to the results of some tests is not always clear-cut. If a set of tests give conflicting advice as to the appropriateness of a particular method, it becomes important to decide not only whether certain properties are present but also their degree. This gives us a basis for estimating the compatibility of each property.

We have taken for our model the system recommended by Lucks and Gladwell which uses a system of measurement of compatibility allowing for interaction and conflict between a number of attributes. All of these processes may not be required if the choice is clear-cut e.g. we have an integral to calculate which has a particular singularity structure for which one particular method has been specifically constructed. However, for more difficult cases a composite picture should be built up to calculate a true measurement.

How the compatibility functions interpret the measurements of various attributes is up to them and may vary between differing methods. It is this area that takes as its basis the judgement of Numerical Analysis ‘experts’ whether that be from the documentation (which may be deficient in certain respects) or from alternative sources. However, its assessment of the suitability or otherwise of a
particular method is reflected in a single normalised value facilitating the direct comparison of the suitability of a number of possible methods.

\downlink{ Examples }{UXANNAEx}
\end{page}

\section{Computational Agents}

\begin{page}{UXANNAAgent}{Computational Agents}
\begin{scroll}

Computational Agents are those program segments which investigate the attributes of the input function or functions, such as \textbf{stiffnessAndStabilityOfODEIF} (the \textit{IF} indicates that it is an \textit{Intensity Function} i.e. one that returns a normalised real number or a set of normalised real numbers). They are usually functions or programs written completely in the Axiom language and implemented using computer algebra.

Some agents will be common to more than one problem domain whereas others will be specific to a single domain. They also vary greatly in their complexity. It is a fairly simple task to return details about the range of a function since this information will have been included in the problem specification. It is a different order of complexity to return details of its singularity structure.

As an example, here is a call to the computational agent \textbf{singularitiesOf} to obtain the list of singularities of the function $\tan x$ which are in the range $0..12\pi$:

\spadpaste{s := singularitiesOf(tan x, [x], 0..12*\%pi)$ESCONT \free{lib3} }
Each of these computational agents which may be called by a number of method domains retain their output in a dynamic hash-table, so speeding the process and retaining efficiency.

Due to the awesome programming skills of Scott Morrison the htadd program will use the original source file in literate form to build the ht.db

| * |

\[$\{PAGEFILE\}$: $\{BOOK\}$
@echo 1 making $\{PAGEFILE\}$ from $\{BOOK\}$
@cp $\{BOOK\}$ $\{PAGEFILE\}$

| * |

\[\%
@echo 1 making $\{HYPER\}/$*.ht from $\{BOOK\}$
@echo '($tangle "$\{BOOK\}$ "$\{HYPER\}/$*.ht")' | \n  $\{OBJ\}$/SYS/bin/lisp

The patch/paste files are now included directly in bookvol7.1 Add new patch/paste files is a manual process when editing the book.

| * |

\[$\{HYPER\}/ht.db$: $\{BOOK\}$
@echo 2 making $\{HYPER\}$ from $\{BOOK\}$
@ (cd $\{HYPER\} ; \n
